"The partially dried, ripe fruit of *Serenoa serrulata* (Michaux) Hooker filius (Fam. *Palmæ*). Preserve Sabal in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.*

The *Saw palmetto* flourishes on the Atlantic coast from South Carolina to Florida, where it forms the so-called "palmetto scrub." According to Schneider it is also found in southern portions of California. (*Pacific Pharm.*, ii, p. 466.) It was introduced into medicine in 1879. (*Bull. Lloyd Library*, 1911, No. 18, p. 71.) The stem of saw palmetto is from 6 to 10 feet high, has a crown of large leaves, long petioled, with a circular fan-shaped leaf blade split at the edge into from 15 to 30 divisions, which are slightly cleft at their apices. The fruit is a one-sided blackish-brown drupe, from half an inch to one inch long; ovoid-oblong in shape, with a somewhat wrinkled exterior, and a sweetish, not agreeable taste. It occurs in a large panicle which in some cases may weigh as much as nine pounds.

Properties.—Sabal is officially described as follows: "Ellipsoidal or ovoid, occasionally compressed, from 1.5 to 3 cm. in length and from 1 to 1.5 cm. in diameter; externally brownish-black to bluish-black, smooth and somewhat oily, with a few large, more or less angular depressions due to the contraction of the inner layer on drying, summit marked by the scar of the style, and the base either with a short stalk or stem-scar; epicarp and sarcocarp together forming a thin coriaceous shell enclosing a hard but thin endocarp, which is externally reddish-brown and somewhat fibrous as is also the inner layer of the sarcocarp; inner layer of endocarp smooth, enclosing a hard, ellipsoidal or ovoid, somewhat flattened, reddish-brown seed; odor pronounced, aromatic; taste sweetish, aromatic, slightly acrid. The powder is yellowish-brown; when examined under the microscope it exhibits large, irregular fragments; parenchyma cells of sarcocarp containing a yellowish-brown or brownish-red, amorphous substance; whitish fragments of endosperm; the walls being considerably thickened and with large pores; stone cells occasional, nearly colorless, more or less tabular or irregular in shape, about 0.125 mm. in length, walls about 0.015 mm. in thickness, and with numerous simple or branching pores." *U. S.*

Kraemer gives an illustrated article on the pharmacognosy of the saw palmetto in the *Practical Druggist*, 1910, xxviii, p. 97. In it Coblentz (*Proc. New Jersey Pharm. Assoc.*, 1895, 45) believes that he found, besides a volatile oil an alkaloid. In the studies of Sherman and Briggs (*Ph. Archiv.*, vol. 2) no alkaloid could be detected. Sieker (*Ph. Rev.*, 1897, 113) examined the fixed oil: the sp. gr. was 0.9138, and it was soluble in alcohol, ether, and petroleum benzin. By pressure the fruit yields about 1½ per cent. of a brownish-yellow to dark red oil, soluble in alcohol, ether, chloroform and benzene, and partly soluble in dilute solution of potassium hydroxide. It contains, according to Sherman and Briggs (*Ph. Archiv.*, 1899, 101; see also *Ph. Rev.*, 1900, 217), about 63 per cent. of free acids, and 37 per cent. of ethyl esters of these acids. The oil obtained exclusively from the nut was thick and of a greenish color, without fruity odor. It was a glyceride of fatty acids.

Vanderkleed and E'we (*Proc. P. Ph. A.*, 1916, p. 284) contribute formulas for syrup of sabal and elixir of sabal with terpin hydrate. The latter is made as follows:

Dissolve 1.75 Gm. of terpin hydrate in 40 mils of fluidextract of sabal and 10 mils of alcohol. Add 1 mil of tincture of sweet orange peel, 0.2 mil of solution of saccharin, 40 mils of glycerin, and 100 mils of syrup. This preparation will contain 8 grains of terpin hydrate and 184 grains of sabal in each fluidounce.

Uses.—The oil of saw palmetto is probably eliminated through the kidneys unchanged, although we know of no actual experiments to prove this, and appears to exert a stimulant alterative action upon the mucous membrane of the genito-urinary tract, similar to that of other alterative diuretics. Saw palmetto is milder and less stimulant than is cubeb or copaiba, or even the oil of sandal-wood. Like these drugs it also has the power of affecting the respiratory mucous membrane, so that it has been used not only in *chronic* and *sub-acute cystitis*, but also in *chronic bronchitis, laryngitis*, and the catarrhs which accompany *asthma, phthisis*, and other more serious diseases of the lungs. It has been

affirmed that saw palmetto is capable of increasing the nutrition of the testicles and of the mammæ in functional atony of these organs, but this is very doubtful. It has been especially recommended in cases of *enlarged prostate* of old men; it is not probable that it has a direct influence upon the prostatic gland itself but there is much clinical testimony as to its value and it probably acts by reducing the catarrhal irritation and the relaxed condition of the mucous membrane of the bladder and urethra, which are almost universally present in prostatic hypertrophy.

Dose, ten to twenty grains (0.65–1.3 Gm.).

SACCHARUM. U. S. (Br.)

SUGAR Sacch. [Cane Sugar, Sucrose]

(săc'ȼha-rŭm)

"Sucrose [$C_{12}H_{22}O_{11} = 342.18$] obtained from cultivated varieties of *Saccharum Officinarum* Linné (Fam. *Gramineæ*), and from *Beta vulgaris* Linné, var. *Rappa* Dumort (Fam. *Chenopodiaceæ*) and from other sources." *U. S.* "Refined Sugar is a crystallised sugar, $C_{12}H_{22}O_{11}$, obtained from the juice of the sugar-cane, sugar-beet, and other plants." *Br.*

Saccharum Purificatum, *Br.*; Refined Sugar, Cane Sugar, Sucrose; Sucre de Canne, *Fr. Cod.*; Sucre, Sucre pur, Sucre en Pains, *Fr.*; Saccharum, *P. G.*; Weisser Zucker; Zucker, Rohrzucker, *G.*; Zucchero, *It.*; Azucar, Azucar refinado, *Sp.*

The *sugar cane, Saccharum Officinarum*, is an herbaceous perennial plant, possessing a jointed, succulent rhizome, from which arises several shining, jointed, solid stems, from an inch to two inches in diameter, from six to twelve feet high, and containing a white and juicy pith. The color of the stem is yellow, greenish yellow, purple, or stripped. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base, are three or four feet long and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green color inclining to yellow. The flowers are pinkish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant has a general resemblance to Indian corn. Four varieties are mentioned: 1, the *common*, with a yellow stem; 2, the *purple*, with a purple stem and richer juice; 3, the *gigantic*, with a very large light-colored stem; and 4, the *Otaheitan*, which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh, and is distinguished by its greater height, the longer intervals between its joints, and the greater length of the hairs which surround the flowers.

Sugar cane was originally indigenous in all probability to India. It has been cultivated for its saccharine juice since remotest antiquity. At the present time it is cultivated in all tropical and sub-tropical countries.

The sugar cane is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be removed. At the end of a year or more the plant flowers, but before this takes place the canes are richest in sugar and are cut down. The quantity of sugar which they yield is variable. According to Avequin of New Orleans, the proportion of cane sugar in the recent stalk is about 10 per cent.; of uncrystallizable sugar from 3½ to 4 per cent. Cane juice is said to contain 17 per cent. of crystallizable sugar, though not more than 13 per cent. is extracted in practice.

The *Sugar beet* (*Beta vulgaris* L.) is extensively grown in temperate zones as a source of sugar, or saccharose. It is extensively grown in Europe and the Northern and Western States. The plant is a biennial resembling the ordinary garden beet. The varieties yielding sugar produce rather small tuberous roots, which are either yellowish or whitish internally. They yield 4 to 15 per cent. of cane sugar, depending upon selection and cultivation.

The term "sugars" is applied to a large number of carbohydrates. A classification of these is given below. The sugar of the Pharmacopœia is known by the chemists as *sucrose*.

The name of *glucosides* has been given to certain organic substances which are resolvable, by the presence of acids, or other slight chemical influence, into glucose and some other proximate principle, as in the instance of one variety of tannic acid, which is resolved into glucose and gallic acid. E. Fisher announced (*Ber. d. Chem. Ges.*, 1893, 2400) the discovery of a general method for the formation of glucosides. He finds that, if a glucose be dissolved in an alcohol and gaseous hydrochloric acid be passed into the solution to saturation, the two compounds unite with the elimination of water to form a glucoside or ester of the two. He has found this reaction to extend to methyl ethyl, propyl, isopropyl, amyle, allyl, and benzyl alcohols, to ethyleneglycol, and glycerine, and even to the oxyacids or alcohol acids like lactic acid. He has tested it for mannose, galactose, dextrose fructose, gluco-heptose, arabinose, xylose, and rhamnose. *Fruit sugar or levulose*, is an isomeric form of glucose, found in honey and in the juice of fruits; an uncrystallizable mixture of dextrose and levulose (both varieties of glucose) is generated from cane sugar by solution in water or weak acids, and long boiling. Hence it is present in molasses. An aqueous solution of this sugar, like grape sugar, is susceptible of the vinous fermentation without an intermediate change. In consequence of its effect on polarized light, which is the opposite of that of the cane sugar from which it is prepared, it has been named by the French chemists *invert sugar* (*sucre interverti*). A solution of *cane sugar*, like that of grape sugar, has a rotating power to the right. When it ferments, it is first changed into uncrystalliza-

ble sugar by the invertase of the yeast, according to the reaction :

$$C_{12}H_{22}O_{11} + H_2O = (C_6H_{12}O_6)_2$$

and, as the change proceeds, the rotating power to the right of the cane sugar gradually lessens and disappears, and is replaced by the rotating power to the left of the levulose which remains behind on account of its fermenting more slowly than the dextrose which is simultaneously formed in the process of inversion.

Classification of the Carbohydrates.—The group of the carbohydrates has been studied by Emil Fischer, who has not only made numerous syntheses in this group, but has greatly widened our knowledge of the relations of the several sugars, permitting a more comprehensive classification than formerly. While no sugars are found in nature containing less than six atoms of carbon, synthetic compounds are formed belonging in the first, or monosaccharide, class which contain three, four, and five atoms of carbon, as well as others containing seven, eight, and nine atoms of carbon. The nomenclature of the sugars is based upon the fact that simple sugar molecules are known which are distinguished by the Greek prefixes tri, tetra, etc., indicating the number of carbon atoms in the molecule; thus, glycerose, $C_3H_6O_3$, is a triose, while dextrose, $C_6H_{12}O_6$, is a hexose. These are called monoses. These simple sugar molecules are taken as the basis for a secondary classification based upon the number of monoses or simple sugar molecules represented in the molecular structure of the more complex members of the group. The Greek numerical prefixes are also used to distinguish these; thus, dextrose, $C_6H_{12}O_6$, is a monosaccharid, while sucrose, $C_{12}H_{22}O_{11}$, is a disaccharid produced by the union of two monosaccharid molecules with the elimination of water. Of the simple sugars, members ranging from three to nine carbon atoms are known (trioses to nonoses), while of the broader groupings, monoses, dioses, trioses (monosaccharids, etc.), contain respectively one, two, or three of the simple sugar molecules, while polyoses or polysaccharids contain an indefinite or larger number of monoses. The classification given below, is based on that of Tollens.

I. Monosaccharides.

Trioses.—Glycerose, $C_3H_6O_3$ (prepared from glycerine by oxidation).

Tetroses.—Erythrose, $C_4H_8O_4$ (prepared from erythrite by oxidation).

Pentoses.—Arabinose, $C_5H_{10}O_5$ (prepared by the action of dilute sulphuric acid upon lævorotatory gum arabic ; xylose, $C_5H_{10}O_5$ (prepared by boiling beech wood and jute with dilute acids); rhamnose or isodulcite, $C_5H_8(CH_3)O_5$, methyl pentose (obtained in the decomposition of glucosides like quercitrin).

Hexoses.—Glucose or dextrose, $C_6H_{12}O_6$; fructose or levulose, $C_6H_{12}O_6$; mannose, $C_6H_{12}O_6$ (obtained by the careful oxidation of mannite) ; galactose, $C_6H_{12}O_6$.

Heptoses.—$C_7H_{14}O_7$. Manno-heptose (obtained artificially from the corresponding mannose) ; gluco-heptose (obtained artificially from the corresponding glucose).

Octoses.—$C_8H_{16}O_8$. Manno-octose (prepared from the corresponding manose) ; gluco-octose (prepared from the corresponding glucose).

Nonoses.—$C_9H_{18}O_9$. Manno-nonose (prepared from the corresponding mannose) ; gluco-nonose (prepared from the corresponding glucose).

II. Disaccharides and Trisaccharides.

Tribioses and tetrabioses are as yet unknown.

Pentabioses.—Arabinon, $C_{10}H_{18}O_9$ (has been prepared by the moderated action of dilute sulphuric acid upon arabic acid).

Hexabioses.—Cane Sugar, $C_{12}H_{22}O_{11}$; milk sugar, $C_{12}H_{22}O_{11}$; maltose, $C_{12}H_{22}O_{11}$; isomaltose, $C_{12}H_{22}O_{11}$; trehalose, $C_{12}H_{22}O_{11}$.

Hexatrioses.—Meletriose or raffinose, $C_{18}H_{32}O_{16}$; melezitose, $C_{18}H_{32}O_{16}$.

III. Polysaccharides.

(*a*) *Crystallizable polysaccharides.*—Gentianose, lactosin.

(*b*) *Uncrystallizable polysaccharides.*—Starches, lichnin, inulin, glycogen, dextrin, natural gums, pectin substances, cellulose, lignin, tunicin.

Cane sugar is manufactured extensively on the continent of Europe from the beet, and this industry is now growing in this country, notably in the western states. It is also largely produced in Canada and the northern parts of the United States from the sap of the sugar maple (*Acer saccharium*). This variety is never refined or purified as it owes its value as a confection and flavor to the impurities naturally present in the crude product. Cane sugar may be obtained from cornstalks, and from the *Chinese sugar cane,* or *Sorghum saccharatum,* which latter source for a time assumed some importance in Kansas and the Northwest. In India, sugar is made from the sap of different species of palm. Crude *palm sugar* is called *jaggery.* Next in rank to the sugar beet as a source of cane sugar is the sugar cane, which is extensively cultivated in Africa, the East and West Indies (especially Cuba), Brazil, and some of our Southern States, particularly Louisiana.

Preparation and Purification.—The canes, when ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between a series of horizontally placed iron rollers in a mill, or they are cut in thin transverse slices and the juice extracted by diffusion with warm water. The juice, constituting 90 per cent. of the cane, though much less is actually obtained, is of a pale greenish color, sweet taste, and balsamic odor, and has a sp. gr. varying from 1.033 to 1.106. As it runs out it is received in suitable vessels, and, being quickly removed, is *immediately* mixed with lime,

in the form of milk of lime, in the proportion of about 1 part of the earth to 800 parts of the juice, and heated in a boiler to 60° C. (140° F.). The exact proportion of the lime cannot be determined, as the juice varies in quality in different seasons; but the manufacturer should aim at leaving the juice still slightly acid. The albuminous matter rises to the top, and forms a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by heat, the scum being carefully skimmed off as it forms. When sufficiently concentrated, the juice is transferred to shallow vessels called coolers, from which, when it assumes a granular aspect, it is drawn off into wooden vessels with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup is allowed to drain off from the sugar, which in this state is granular, of a yellowish color, and moist. The syrup, by a new evaporation, furnishes an additional portion of sugar, and the liquid which finally remains, incapable of yielding more sugar with advantage, is called *molasses*. Sugar produced in this way is called "open pan" sugar. It is now almost completely displaced by "vacuum pan" sugar.

In the production of raw sugars by the vacuum pan process, the juice, after "defecation" with lime and removal of excess of lime by carbonic acid gas, is run through large filters of bone black, and then into a vacuum pan for concentration. The vacuum pan is a large evaporating pan, closed above by a dome-like top, which connects with an exhausting steam pump, so that the liquid can be concentrated under very reduced pressure. The heat is supplied by coils of steam pipes which run through the interior of the pan. The saccharine juice is evaporated in this until it begins to crystallize, and even after this fresh portions are added, so that the crystals already formed grow by accretion of fresh material. After the crystallization is complete, the warm mixture of crystals and syrup is run into "centrifugals," to which a rapid motion of revolution is given, and the crystals so drained and dried.

There is no doubt that a large proportion of the sugar is lost in the ordinary process of manufacture. Melsens, of Brussels, proposed a process, which consists in the use of calcium bisulphite. This salt is alleged to act as an antiseptic, preventing the operation of any ferment; as an absorber of oxygen, opposing the action of that gas on the juice; as a clarifier, rendering insoluble at 100° C. (212° F.) all coagulable matters; as a bleacher of pre-existing coloring matters, and a preventive of the formation of a new ones; and, lastly, as a substance furnishing a base to neutralize hurtful acids, which unite with the lime, displacing the weaker sulphurous acid. This process is now largely used, and calcium bisulphite is used in British Guiana and other sugar-producing countries in immense quantities. Émil Pfeiffer proposed another refining process, which consists in the use of acid calcium phosphate, an agent previously recommended by Brande. Reynoso considered alumina the best defecating agent, having succeeded by means of it in throwing down almost all impurities most hurtful. He adds the acid aluminum phosphate to the cane juice, and decomposes this with lime, by which the calcium phosphate is produced and alumina separated, and all these, with some lime in excess, cause the elimination of coloring and nitrogenous matters, so that there remain in the liquid only some of the salts which normally accompany the sugar in the juice. (*J. P. C.*, 4e sér., ii, 232.)

The refining of brown sugar forms a distinct branch of business, and the methods pursued have undergone many improvements. The sugar is first "melted"—that is, dissolved in hot water—and then sometimes clarified by heating it with bullock's blood, although sulphites, phosphates, and other defecating agents may be used. The clarified syrup is then strained through cloth filters, whereby it is rendered limpid. The clear straw colored syrup from the bag filters is then run into the char filters —that is, large filters filled with freshly ignited bone black. The syrup after filtration goes to the vacuum pans. This great step in advance was taken by Philip Taylor and Howard. The former introduced the improvement of heating the syrup with great rapidity by means of steam made to pass through a series of tubes traversing the boiler, and the latter devised the plan of causing the syrup to boil under a diminished pressure, created by a suction pump, set in motion by a steam engine, while it was heated by steam circulating round the boiler. In this way the syrup was made to boil at a lower temperature, and with a diminished contact of the air, and the loss of cane sugar by change in to that which was uncrystallizable was in great measure avoided. Two, three, or even four vacuum pans may be coupled together, so as to economize fuel, and the vapors arising from one made to heat the next, in which a more perfect vacuum exists, allowing of evaporation at still lower temperatures. Such a combination is called a double, triple, or quadruple effect apparatus.

The process of forming *loaf sugar* by claying and displacing colored syrup by white syrup is now almost entirely replaced by the process already described under raw sugars of crystallizing in the vacuum pan and draining with a centrifugal. At one time it was the custom to discontinue the decolorization process before an entirely white sugar was obtained, and then to add a small amount of ultramarine blue to overcome the yellow appearance of the granulated sugar. This process has practically been abandoned within recent years. The syrups of lowest quality are employed in forming in-

ferior white sugar, from which a syrup finally drains containing so little cane sugar as not to repay the expense of extracting it. This constitutes *sugar-house molasses.* Good brown sugar, in the process of refining, yields about 70 per cent. of white sugar. The application of animal charcoal to the refining of sugar is now very extensive. A comprehensive historical article by C. A. Browne, on the development of the sugar industry is found in the *A. J. P.*, 1915, p. 10.

Commercial History.—*Cane sugar* was known to the ancients. It was originally obtained from India, where it was extracted from the sugar cane. About the period of the Crusades, the Venetians brought it to Europe; but at that time it was so scarce and costly as to be used exclusively as a medicine. Upon the discovery of the Cape of Good Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Subsequently the cultivation of the cane extended to Arabia, Egypt, Sicily, Spain, and the Canaries, and finally, upon the discovery of the New World, to America, where it was pursued with the greatest success, and continues to be so. In America it was produced most abundantly in the West Indies, which supplied also a part of the consumption of Europe. The Cuban production has grown rapidly in recent years, having been 2,582,845 tons in 1915, and estimated to have been 3,000,000 tons in 1916. The production in Louisiana, once large, diminished under the competition of the foreign beet sugar production, but in recent years, under the stimulus of a bounty, it has increased, and now amounts to about 300,000 tons per year. However, the American production from the sugar beet has developed rapidly, and in 1915 amounted to 722,054 tons. This production centers in California, Nebraska, Utah, Michigan, Colorado, and Montana, and is now greatly on the increase.

The European production, owing to the war conditions, decreased from 9,000,000 tons to 6,350,000 tons during 1916.

The importations of raw sugars into the United States for 1915 were 2,710,491 tons, valued at $173,992,600.

Properties.—Sugar, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosphorescent by friction, and of the sp. gr. 1.6. It forms "white, hard, dry crystals or as a white, crystalline powder, odorless, and having a sweet taste. It is permanent in the air. One Gm. of Sugar dissolves in 0.5 mil of water and in 170 mils of alcohol at 25° C. (77° F.); also in slightly over 0.2 mil of boiling water; insoluble in chloroform or ether. Its aqueous solution (1 in 20) is neutral to litmus and is dextrorotatory. The specific rotation $[\alpha]_D$ of Sugar, determined at 20° C. (68° F.), in a solution in distilled water, containing in 100 mils the equivalent of 26 Gm. of Sugar, previously dried to a constant weight at 105° C. (221° F.), and using a 200 mm. tube, is not less than +65.9° (see Part III, Test No. 21). Its aqueous solution saturated at 25° C. (77° F.) has a specific gravity of about 1.340. Incinerate about 2 Gm. of Sugar; not more than 0.05 per cent. of ash remains. An aqueous solution of Sugar (2 in 1) is colorless when viewed horizontally through a vertical cylinder of colorless glass having an inside diameter of about 25 mm. When kept in large, well-closed, and completely filled bottles, the solution deposits no sediment on prolonged standing (*insoluble salts, ultramarine, Prussian-blue*). Ten mil portions of an aqueous solution of Sugar (1 in 10) tested separately give no precipitate with an equal volume of hydrogen sulphide T.S., and not more than a faint opalescence with a few drops of ammonium oxalate T.S. (*calcium*), barium nitrate T.S. (*sulphate*), and silver nitrate T.S. (*chloride*). Dissolve 20 Gm. of Sugar in enough distilled water to make 100 mils and filter the solution if necessary. To 50 mils of the clear liquid, contained in a 250 mil beaker, add 50 mils of alkaline cupric tartrate V.S., heat the mixture at such a rate that approximately four minutes are required to bring it to the boiling point, and then boil it for exactly two minutes. Add 100 mils of cold, recently boiled distilled water, and collect and weigh the precipitated cuprous oxide in the following manner: Prepare a Gooch crucible with an asbestos layer. Thoroughly wash the asbestos with distilled water, followed successively by 10 mils of alcohol and 10 mils of ether; dry at 100° C. (212° F.) for thirty minutes and then weigh the prepared crucible. Collect the precipitated cuprous oxide on the asbestos, thoroughly wash it with hot distilled water, then with 10 mils of alcohol, and finally with 10 mils of ether and dry it at 100° C. (212° F.). The weight of the cuprous oxide does not exceed 0.155 Gm., corresponding to not more than 0.5 per cent. of invert sugar." *U. S.*

"Colorless and inodorous crystals, or in crystalline masses. Readily and completely soluble in half its weight of *water,* forming a clear, colorless and odorless syrup which does not develop an unpleasant odor when acidified with *hypophosphorous acid* and allowed to stand for twenty-four hours; the syrup, heated to about 82° C. (179.6° F.) with *solution of potassio-cupric tartrate,* does not yield more than a trace of a red or yellow precipitate (absence of glucose). Yields no *reactions* for barium, strontium, calcium, chlorides, or sulphates. Ash not more than 0.05 per cent." *Br.*

Its solution, when thick and strong, is called *syrup,* and when alcohol is mixed with it, the sugar is gradually deposited in crystals. An aqueous solution of sugar, kept in a warm place, has the property of corroding iron, partially immersed in it, just above the line where the surface of the liquid touches the metal, and the solution itself becomes impregnated with ferrous oxide, and of a deep red-brown color. A similar effect is produced on lead, but zinc and copper are but slightly acted on. A solution of sugar possesses the property also of dissolving a large quantity of calcium hydroxide, forming a compound called *calcium*

saccharate. When a concentrated syrup is gently heated, and spirit added to it, the liquid, on cooling, forms white semi-transparent crystals of hydrated sugar, having the shape of oblique four-sided prisms, and called *rock candy.* When heated to 185° C. (365° F.), it melts into a viscid, colorless liquid, which on being suddenly cooled forms a transparent mass, called *barley sugar.* At a higher temperature, between 204.4° and 215.5° C. (400° and 420° F.), it loses two molecules of water, and is converted into a black syrupy liquid called *caramel,* which is now official in the N. F. IV. (See Part II.) At a still higher temperature it yields combustible gases, carbon dioxide, empyreumatic oil, and acetic acid, and there remains about one-fourth of its weight of charcoal, which burns without residue. Sugar renders the fixed and volatile oils to a certain extent miscible with water, which is probably a colloidal suspension; such mixtures are called *oleo-saccharures.* When in solution, it is not precipitated by lead subacetate, a negative property which distinguishes it from most other organic principles.

Sugar is sometimes adulterated with crystallized glucose, and it is a common practice among many sugar refiners to "blue" sugar to conceal the yellowish tint due to insufficient refining; ultramarine was formerly largely used, but the practice has been discontinued. See the official test above. Cane sugar may be distinguished from grape sugar by the fact that it does not reduce alkaline copper tartrate (see official tests), nor basic bismuth nitrate (see *Nylander's Reagent,* Part III). Cane sugar, similarly treated, has no effect on the test. Donaldson's test for sugar in the *animal fluids* is formed of 5 parts of sodium carbonate, 5 of potassium hydroxide, 6 of potassium bitartrate, 4 of copper sulphate, and 32 of distilled water. A few drops of this solution being added to an animal fluid, and the mixture heated over a spirit-lamp, a yellowish-green color is developed, if sugar be present. M. J. Nicklés recommends carbon tetrachloride as a test for distinguishing glucose from cane sugar. This liquid, mixed with cane sugar in a glass tube, kept for some time near 100° C. (212° F.), causes a darkening of the sugar, gradually increasing until it becomes black. Glucose undergoes no such change. (*J. P. C.,* 4e sér., iii, 119.)

Action of Acids and Alkalies.—The mineral acids act differently on cane sugar according as they are concentrated or dilute. Strong nitric acid, with the assistance of heat, converts it into oxalic acid. (See *Oxalic Acid.*) The same acid, when weak, converts it into *saccharic acid,* confounded by Scheele with malic acid. Concentrated sulphuric acid chars it. Diluted hydrochloric acid, when boiled with cane sugar, converts it into a solid, brown, gelatinous mass. Weak sulphuric acid, by a prolonged action at a high temperature, converts cane sugar, first into uncrystallizable invert sugar, afterwards into grape sugar, and finally into *ulmin* and *ulmic acid.* Vegetable acids are supposed to act in a similar way. Maumené found that cane sugar undergoes the change into invert sugar when kept for a long time in aqueous solution, as well as when heated with acids. When the boiling with acids is prolonged for several days in open vessels, oxygen is absorbed, and, besides ulmin and ulmic acid, formic acid is generated. Soubeiran admits the change of the uncrystallizable into grape sugar, but attributes it to a molecular transformation of the sugar, independently of the action of the acid, as, according to his observation, the conversion takes place only after rest. In confirmation of his views, this chemist states that he found the same changes to be produced by boiling sugar with water alone.

Cane sugar unites with the alkalies and some of the alkaline earths, forming definite combinations which render the sugar less liable to change. It also unites with lead monoxide. Boiled for a long time with aqueous solutions of potassium hydroxide, the liquid becomes brown, formic acid is produced, and two new acids are generated,—one brown or black and insoluble in water, called *melassic acid,* the other colorless and very soluble, named *glucic acid.* Alkalies and the alkaline earths are said to lessen the rotatory power of sugar in relation to polarized light, but the sugar recovers its power when the alkali is saturated. (*J. P. C.,* 4e sér., iv, 314.) The action of acids and alkalies on cane sugar explains the way in which lime acts in the manufacture and refining of sugar. The acids naturally existing in the saccharine juice have the effect of converting the cane sugar into invert sugar, by which a loss of the sucrose is sustained. The lime, by neutralizing these acids, prevents this change. An excess of lime, however, must be carefully avoided, as it injures the product of cane sugar in both quantity and quality. The change in sugar which precedes fermentation, namely, the conversion of cane sugar into the uncrystallizable invert sugar, points to the necessity of operating on the juice before that process sets in, and hence the advantage of grinding canes immediately after they are cut, and boiling the juice at once.

Molasses, sometimes Latinized in prescriptions as *Syrupus Fuscus,* is of two kinds, the West India and sugar-house. *West India molasses* is a black thick liquid, of a peculiar odor and sweet empyreumatic taste. When mixed with water and with the skimmings of the vessels used in the manufacture of sugar, it forms a liquor which, when fermented and distilled, yields *rum. Sugar-house molasses, golden drips,* or *grocer's syrup* is thicker than the West India molasses, and has a different flavor; as found in commerce, it is sometimes adulterated with glucose. Its sp. gr. is about 1.4, and it contains about 75 per cent. of solid matter. Both kinds of molasses contain uncrystallizable sugar, more or less cane sugar which has escaped separation in the process of manufacture or refining, and gummy and coloring matter. *New Orleans molasses* was formerly the most largely used variety, but has practically disappeared

from the market, owing to the changed conditions of manufacture.

Uses.—Although sugar is so important a foodstuff to-day, it does not seem to have been widely employed in Europe until the tenth or eleventh century. It was known much earlier to the European writers, such as Dioscorides, who lived in the first century, by whom it seems to have been regarded as a sort of a natural curiosity. Its food value is very high, commercial cane sugar yielding more than 4 calories of energy per gramme. It is not, however, directly utilizable by the body cells, but must first be inverted into dextrose or levulose; this is true also of the other disaccharids such as lactose and maltose. This inversion is accomplished in the system probably in part by the hydrochloric acid of the gastric juice, but chiefly by a specific ferment which is found throughout the whole small intestines. It occurs with great rapidity so that the body can derive energy from ingested cane sugar almost as rapidly as it can be absorbed. So rapidly, indeed, is sugar absorbed from the intestinal tract that eating large quantities of it may overwhelm the inability of the liver to withdraw the sugar from the blood and lead to hyperglycemia and the appearance of glucose in the urine; a condition which is known as alimentary glycosuria. Glucose and levulose are directly assimilable and the body can derive nourishment from them even when injected hypodermically or intravenously.

A large portion of the muscular energy is derived from the oxidation of the blood sugars. There is reason to believe that increasing the amount of sugar in the blood, thereby offering to the working muscle readily-oxidizable, energy-yielding form of carbon, not only increases its immediate efficiency but lessens the call upon the fuel stored up within it. It is to this mechanism and the rapidity of its absorption that sugar owes its power of banishing the sense of fatigue from muscular exertion. Dixon (*J. P.*, 1907, xxxv, p. 346) has shown that a similar effect is produced upon the heart muscle and sugar has been used as a stimulant in the treatment of acute *heart failure*. Denyer (*L. L.*, April 5, 1913) reported a case of severe heart failure in which life was apparently saved by the daily use of 4 ounces of cane sugar by the mouth. Buedingen (*D. A. K. M.*, 1914. cxiv, p. 534) injected intravenously a solution of glucose isotonic with the blood (5.4 per cent.) in the treatment of *heart disease* with asserted good results.

According to S. Meslach, glucose, when given in doses of from six to six and a half ounces per day in the form of the concentrated syrup, acts as a powerful diuretic, and is very useful in the treatment of *cardiac dropsy*. If the kidneys be healthy, the glucose is said not to appear in the urine. The celebrated grape cure of Europe is said to act by virtue of the glucose in the grape.

Schreiber (*Ther. Geg.*, 1913, p. 195) asserts that intravenous injections of glucose increase the coagulability of the blood and are useful in internal *hemorrhages*, but as Kuhn (*D. Z. Chir.*) reached the opposite conclusion and recommends it to prevent *thrombosis*, it seems improbable that it has any marked effect. Magnus (*M. M. W.*, 1913, p. 406) claims that sugar has valuable antiseptic properties and recommends it in the treatment of various forms of *wounds*. *Schuecking's solution* consists of 0.08 p. c. of common salt, 0.033 p. c. of sodium saccharate ($C_{12}H_{21}O_{11}Na$) and in some cases also 0.003 to 0.015 p. c. calcium mono-saccharate. It is used for intravenous injection instead of physiological salt solution in *circulatory failure* and is said to directly stimulate the heart.

The discovery of Minkowski (*T. M.*, 1892), that in dogs, after extirpation of the pancreas, levulose, given in moderate quantities, is consumed in the system, has led to the use of it as a food substitute for true sugar in *diabetes* with some success. As much as two ounces of it a day are sometimes well borne, but levulose frequently appears in the urine when more than one ounce has been given daily and rarely should this amount be exceeded. According to Lepine, levulosuria is likely to occur when there is hepatic disease. Levulose has no direct influence upon the disease but is an addition to the dietary. Under the name of *diabetin* it has been largely advertised as a proprietary preparation. Levulose has been strongly recommended in *phthisis*, in the dose of 4 to 6 tablespoonfuls a day, also as a substitute for sugar of milk for infants when an aperient property is not desired.

Sugar is much used for the purposes of preserving organic substances. It is probable that it acts by producing rapid exosmose of the fluids of the fermentative organisms, its diluted solution being in fact prone itself to undergo fermentative change. All the different kinds of sugar susceptible of the alcoholic fermentation have this power. In pharmacy, sugar is employed to render oils miscible with water, to cover the taste of medicines, to give pharmaceutical preparations consistency, to preserve them from change, and to protect certain ferruginous preparations from oxidation. Accordingly, it enters into the composition of several mixtures, pills, and powders, of syrups and confections, and of all the troches. *Molasses* is used as an excipient for pills, and on account of its hygroscopic properties it prevents hardening.

SACCHARUM LACTIS. U. S., Br.

SUGAR OF MILK Sacch. Lact.
[Milk Sugar, Lactose]

(săc'ȼhą-rŭm lăc'tĭs)

"Lactose [$C_{12}H_{22}O_{11} + H_2O = 360.19$] obtained from the whey of cow's milk. Preserve it in tightly-closed containers." *U. S.* "Milk Sugar is a crystallised sugar, $C_{12}H_{22}O_{11},H_2O$, obtained from the whey of milk." *Br.*

Lactin, Milk Sugar; Lactose; Suere de Lait, *Fr. Cod.*; Saccharum Lactis, *P. G.*; Milchzucker, *G.*; Lattosio, Zucchero di latte, *It.*; Lactosa, Azucar de leche, *Sp.*

Preparation.—Sugar of milk is found only in milk, of which it forms about 5 per cent. (Boussingault). It is manufactured largely in Switzerland and the Bavarian Alps, especially from the whey left over in cheese making. In preparing it, milk is first coagulated by the addition of a little diluted sulphuric acid, and the resulting *whey* boiled down to about one-fifteenth of its original bulk into a brown, viscid, sweetly saline mass, which is put into tubs, where, in from twenty-four to forty-eight hours, the sugar crystallizes in a bright yellow granular mass, constituting the so-called "sugar-sand," which is afterwards decolorized by animal charcoal and repeated crystallizations. (*Am. Drug.*, Sept., 1884.) Within recent years the numerous "creameries" in the United States have produced milk sugar in such large quantities as a by-product that its importation from Switzerland has almost ceased. The American method of manufacturing sugar of milk is radically different from that followed abroad, and it is thus described by LaWall (*Alumni Report Philadelphia Coll. Pharmacy,* April, 1902): The whey left after the first curdling of the milk (by the separator system) is run into vats, and treated with about 1 per cent. of hydrochloric acid to remove remaining proteid matters, the liquid being heated to the boiling point, and exactly neutralized with calcium hydroxide. The whey is then generally filtered through a filter press and evaporated in vacuo to a thick syrup, run into pans, and allowed to stand for two days, when granular crusts form. These are then centrifuged and washed with cold water to remove calcium chloride and soluble impurities, and the washings are reserved for future operations. The crude milk sugar is of a very light yellow color, and has little taste or odor. It is redissolved in water and the solution filtered through bone black in percolators. The colorless syrupy percolate is concentrated in vacuo to a pasty mass, which is placed in a centrifuge and washed with cold water. The mass is then dried on strainers in a drying chamber at 60° C. (140° F.), powdered in a ball mill, and bolted.

The *casein* obtained by acidulation of the skim milk, and subsidence, is washed and heated with water containing a small amount of sulphuric acid, to remove impurities. The moist pulpy mass left after the removal of the water is then shredded by means of cutting knives run by a high-speed engine, the flakes being removed in wire gauze frames and rapidly dried with a current of air at 140° F. (60° C.). It is then powdered with high-speed disintegrators. See a paper on the American Milk Product Industry by J. W. England. (*Proc. A. Ph. A.*, 1902, 354.)

Properties.—"Sugar of Milk occurs in white, hard, crystalline masses, or as a white powder, producing a gritty sensation on the tongue; odorless, and having a faintly sweet taste. It is permanent in the air. It readily absorbs odors. One Gm. of Sugar of Milk dissolves in 4.9 mils of water at 25° C. (77° F.); also in 2.6 mils of boiling water; almost insoluble in alcohol; insoluble in chloroform or ether. An aqueous solution of Sugar of Milk (1 in 20) is neutral to litmus and is dextrorotatory. The specific rotation $[a]_D$ of Sugar of Milk, determined at 25° C. (77° F.), in a solution in distilled water, containing in 100 mils the equivalent of 10 Gm. and using a 200 mm. tube, is from +52.2° to +52.5° (see Part III, Test No. 21). Add an equal volume of sodium hydroxide T.S. to 5 mils of a hot, saturated, aqueous solution of Sugar of Milk and gently warm the mixture; the liquid turns yellow and finally brownish-red. On the subsequent addition of a few drops of cupric sulphate T.S., a precipitate of cuprous oxide appears. Incinerate about 1 Gm. of Sugar of Milk; not more than 0.1 per cent. of ash remains. A solution of 3 Gm. of Sugar of Milk in 10 mils of boiling distilled water is odorless, clear, and colorless or at most faintly yellow. Add 20 mils of alcohol (70 per cent. by volume) to 2 Gm. of Sugar of Milk in a fine powder, shake the mixture frequently during half an hour at 15° C. (59° F.) and then filter it. Ten mils of the filtrate remains clear after admixture with an equal volume of dehydrated alcohol (*dextrin*), and this liquid, upon evaporation on a water bath, leaves not more than 0.03 Gm. of residue (*sucrose or glucose*). An aqueous solution of Sugar of Milk (1 in 20) does not respond to the Test for heavy metals (see Part III, Test No. 3). On boiling about 1 Gm. of powdered Sugar of Milk with 50 mils of distilled water and cooling the solution, no blue color is produced upon the addition of one drop of iodine T.S. (*starch*)." *U. S.*

"A white powder, or in crystalline masses; no odor, taste slightly sweet. Soluble in 7 parts of cold *water* and in about 1 part of boiling *water*. 5 grammes dissolved in *water* require for neutralisation not more than 1.5 millilitres of *N/10 solution of sodium hydroxide* (limit of acidity). When 5 grammes are well shaken with 20 millilitres of *alcohol* (90 per cent.) and filtered, the filtrate leaves no appreciable residue on evaporation (absence of sucrose). Ash not more than 0.25 per cent." *Br.*

In commerce sugar of milk frequently occurs in cylindrical masses, the axis of which is a wooden stick, around which the crystals have been deposited. Experiments have shown that much of the milk sugar of commerce contains micro-organisms which have resulted from the decomposition of animal constituents in milk, and the tests of the Pharmacopœias do not exclude such impurities. (*D. C.*, 1893, 250; *Bull. Pharm.*, 1893, v. 5; *P. J.*, 1894, 853.) Its specific gravity is 1.54. It is not susceptible of the vinous fermentation by the direct influence of yeast; but after the action of dilute acids, which first convert it into a variety of glucose, it is capable of furnishing a spirituous liquor. It is well known that both mares' and cows' milk, after becoming

sour, are capable of forming an intoxicating drink, by fermentation. By the action of nitric acid, sugar of milk is converted into mucic acid. When anhydrous it consists of $C_{12}H_{22}O_{11}$; when crystallized, of $C_{12}H_{22}O_{11} + H_2O$. (Staedeler and Krause.) These formulas make anhydrous sugar of milk isomeric with cane sugar. Sugar of milk, when treated with weak sulphuric acid, is inverted or changed into a mixture of *galactose* and *dextrose*, both of the formula $C_6H_{12}O_6$. The galactose crystallizes in fine needles, fusing at 163° C. (325.4° F.).

Sugar of milk is sometimes adulterated with cane sugar or glucose; Hynson and Dunning (*Proc. A. Ph. A.*, 1901, 207) give the following tests for cane sugar and glucose: The test solution is composed of resorcinol 3 parts, hydrochloric acid 1 part, alcohol 100 parts. Dissolve 0.1 Gm. of the suspected milk sugar in a few drops of water contained in a porcelain dish and add to this solution 5 or 6 drops of the test solution. Evaporate slowly over a spirit lamp and allow the outer edge of the solution to boil a little, then tip the dish to one side. On the surface left moist by the receding liquid continue the heat gently. If a trace of cane sugar be present there will appear flashes of vermilion color over the surface treated. If there be an appreciable amount (5 to 10 per cent.) of cane sugar present a vermilion mirror will be formed which can be more clearly seen upon carefully evaporating the entire solution. The evaporation must take place slowly as the sugars will easily char if exposed to too much heat. A brownish-red color quickly charring and not spreading must not be mistaken for cane sugar. This coloration is caused by the milk sugar but need not be confused with the vermilion coloration of cane sugar.

J. W. England (*Proc. Penna. Pharm. Assn.*, 1915, p. 240) reported upon 17 lots of milk sugar, aggregating one-half million pounds, which showed a minimum purity of 99.73 per cent. by the polariscope with negligible traces of nitrogen, ash, and fat.

Uses.—Sugar of milk differs physically from cane sugar in the fact that it is less sweet. Because of its relative tastelessness it is sometimes preferred as an article of diet, especially in the feeding of infants, especially also, because it does not readily undergo the alcoholic fermentation. Its relation to metabolism is precisely the same as that of cane sugar except that the inversion into galactose takes place after its absorption and is probably accomplished by the epithelial cells of the intestines. Like other crystalloids when ingested in large quantities by modifying the osmotic relations of the blood it acts as a diuretic and has been practically used for this purpose by Germain Sée and others with advantage in the treatment of *cardiac dropsies*. If the kidneys be sound the lactose is said not to appear in the urine. It is used in doses of from 6 drachms to 6 ounces (23.5–186 grammes). It is used as a diluent in various official preparations.

SALICINUM. U. S., Br.

SALICIN Salicin.

(sāl-ĭ-cī′nŭm)

"A glucoside [$C_{13}H_{18}O_7$ = 286.14] obtained from several species of *Salix* and *Populus* (Fam. *Salicaceæ*). Preserve it in well-closed containers." *U. S.* "Salicin, $C_{13}H_{18}O_7$, is a crystalline glucoside, which may be obtained from the bark of various species of Salix, and of Populus." *Br.*

Orthohydroxybenzylglucoside; Salicine, *Fr.*; Salicin, *G.*; Salicina, *It.*

The discovery of salicin is claimed by Buchner of Germany, and Fontana and Rigatelli of Italy; but Leroux of France, deserves the credit of having first accurately investigated its properties. The following is Merck's process for its extraction: A boiling concentrated decoction of the bark is treated with litharge until it becomes nearly colorless. Gum, tannin, and extractive matter, which would impede the crystallization of the salicin, are thus removed from the liquid, while a portion of the oxide is dissolved in combination probably with the salicin. To separate the lead, sulphuric acid is first added, and then barium sulphide, and the liquor is filtered and evaporated. Salicin is deposited, and may be purified by repeated solution and crystallization. Erdmann has given another process. Sixteen ounces of the bark are macerated for twenty-four hours in four quarts of water mixed with two ounces of lime, and the whole is then boiled for half an hour. The process is repeated with the residue. The decoctions having been mixed, and allowed to become clear by subsidence, the liquor is poured off, concentrated to a quart, then digested with eight ounces of ivory black, filtered, and evaporated to dryness. The extract is exhausted by spirit containing 28 per cent. of alcohol, and the tincture evaporated so that the salicin may crystallize. This is purified by again dissolving, treating with ivory black, and crystallizing. Merck obtained 251 grains from 16 ounces of the bark and young twigs of *Salix Helix*, and Erdmann 300 grains from the same quantity of the bark of *Salix pentandra*. It may probably be obtained from any of the willow barks having a bitter taste. T. Fawssett states that the best material for preparing salicin is undoubtedly the willow peelings, obtained as refuse from a basket factory, and known in Belgium as "rood schors." David Brown states that the peelings are produced from *Salix fragilis*, while Crispo considers the source to be *Salix purpurea*. These peelings should be used soon after they are stripped from the twigs, and the method of preparing salicin may be conducted as follows: Macerate willow peelings in water for some hours at a temperature as much below the boiling-point as will exhaust them. Strain and remove all moisture from the marc by hydraulic pressure. Evap-

orate the fluidextract thus formed to a low bulk (*in vacuo*). Precipitate the tannin and extractive by treating the liquid successively with quick lime, lead acetate and lead subacetate, in the order named. Remove an excess of any of these precipitants with oxalic acid. Filter and evaporate the clear solution until crystals appear. This treatment generally sufficed to obtain a satisfactory product, but sometimes a final purification with animal charcoal was necessary. (*P. J.*, June 6, 1903, 784.) For a paper by Jowett on the percentage of salicin obtained from various kinds of willow bark see *Y. B. P.*, 1902, 483, and 1903, 474. Braconnot procured it from various species of *Populus*, particularly *P. tremula*, or European aspen.

Properties.—When pure, salicin is in white, shining, slender crystals, inodorous, but very bitter, with the peculiar flavor of the bark. It is soluble in cold water, much more so in boiling water, soluble in alcohol, and insoluble in ether and oil of turpentine. It neutralizes neither acids nor salifiable bases, and is not precipitated by any reagent. Concentrated sulphuric acid decomposes it, receiving from it an intense and permanent bright-red color, this is called the *rutilin reaction*. It is officially described as in "colorless, silky, shining, crystalline needles or rhombic prisms, or as a white, crystalline powder; odorless, and having a very bitter taste. One Gm. of Salicin dissolves in 23.5 mils of water and in 88.5 mils of alcohol at 25° C. (77° F.); also in 3.3 mils of water at 80° C. (176° F.) and in 30 mils of alcohol at 60° C. (140° F.); insoluble in chloroform or ether. Its aqueous solution (1 in 30) is neutral to litmus and is lævorotatory. It melts between 198° and 202° C. (388.4° and 395.6° F.). Heat a small portion of Salicin in a test tube until it turns brown, then add a few mils of distilled water, and afterwards a drop of ferric chloride T.S.; a violet color is produced. Salicin with sulphuric acid gives a red color which disappears upon the addition of distilled water. Heat gently about 0.1 Gm. of Salicin with about 0.2 Gm. of potassium dichromate and 2 mils of diluted sulphuric acid; the fragrant odor of salicylic aldehyde is developed. Incinerate about 2 Gm. of Salicin; not more than 0.05 per cent. of ash remains. Ten mils of an aqueous solution of Salicin (1 in 50) is not colored violet by a few drops of ferric chloride T.S. (*salicylic acid*). Separate portions of 10 mils each of an aqueous solution of Salicine (1 in 50) yield no precipitate on the addition of 1 mil of tannic acid T.S., picric acid T.S., or mercuric potassium iodide T.S. (*alkaloids*). An aqueous solution of Salicin does not respond to the Test for heavy metals (see Part III, Test No. 3)." *U. S.*

"Colorless, shining, trimetric, tabular crystals, or white, crystalline powder. Taste very bitter. Soluble in 28 parts of *water*, and in 80 parts of *alcohol* (90 per cent.); insoluble in *ether*. Melting point from 200° to 201° C.(392°–393.8° F.). Colored red by *sulphuric acid*. When 0.1 gramme is gently heated with 0.2 gramme of *potassium bichromate* and 2 millilitres of *diluted sulphuric acid* an odor recalling meadow-sweet is developed. No appreciable ash." *Br.*

It belongs to the class of glucosides, being resolved by boiling with diluted hydrochloric and sulphuric acids into grape sugar and *saligenin*, according to the reaction:

$$C_{13}H_{18}O_7 + H_2O = C_6H_{12}O_6 + C_7H_8O_2$$

Saligenin, which is ortho-oxybenzyl alcohol, $C_6H_4(OH)CH_2OH$, is converted by further boiling with dilute acids into a resinous body, *saliretin*, $C_{14}H_{14}O_3$. Nitric acid produces with salicin at first two principles called respectively *helicin*, $C_{13}H_{16}O_7$, and *helicoidin*, $C_{26}H_{32}O_{14}$, and afterwards picric and oxalic acids. (*J. P. C.*, xxx, 43.) Distilled with potassium dichromate and sulphuric acid, salicin yields, among other products, a volatile oleaginous liquid, identical with one of the components of oil of spiræa, and recognized as *salicyl aldehyde*, $C_7H_6O_2$ (incorrectly called *salicylous acid*), while saligenin, $C_7H_8O_2$, is the alcohol, and salicylic acid, $C_7H_6O_3$, the acid corresponding. The synthesis of salicin has been effected by Michael (*A. J. P.*, 1879, 492), who obtained first helicin by the reaction of acetochlorhydrose and salicyl aldehyde, and, by the action of nascent hydrogen upon this, salicin.

Uses.—Salicin acts upon the stomach probably as a simple bitter, and after absorption as a feeble and uncertain form of salicylic acid, since it is rapidly, although not completely, decomposed in the system, the products of its change appearing in the urine fifteen to thirty minutes after the ingestion of a single dose. The elimination is partly as salicin, partly as salicylic acid, partly as a salicyluric acid, and partly as saligenin. It has been highly recommended as a substitute for salicylic acid in *rheumatism* by Maclagan and others, but since it owes its activity to its conversion in the blood into salicylic acid and since this conversion is uncertain, salicin is inferior in power to the salicylates. By some it is believed to be less liable to upset the stomach. Salicin has been used as an antiperiodic. One or two drachms may be given in the intermission.

Dose, from ten to thirty grains (0.65–2.0 Gm.).

SANGUINARIA. U. S.

SANGUINARIA Sanguin. [Bloodroot]

(săn-guĭ-nā'rĭ-ą)

The dried rhizome and roots of *Sanguinaria canadensis* Linné (Fam. *Papaveraceæ*). *U. S.*

Blood-root, Red-root, Puccoon, Red Indian-plant, Puccoon-root, Coon-root, White puccoon, Pauson, Snakebite, Sweet-slumber, Tumeric, Red Puccoon, Tetterwort, Red Indian Paint; Sanguinaire, *Fr.*; Blutwurzel, *G.*

Bloodroot (*Sanguinaria canadensis*), or, as it is sometimes called, *puccoon*, is an herbaceous or perennial plant. The rhizome is horizontal,

abrupt, often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown color on the outside, and brighter red within. It is furnished with numerous slender roots, and makes offsets from the sides, which succeed the old plant. From the end of the rhizome arise the scape and leaf-stalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channelled petiole, is reniform, somewhat heart-shaped, deeply lobed, smooth, yellowish green on the upper surface, paler or glaucous on the under, and strongly marked by orange-colored veins. The scape is erect, round, and smooth, rising from a few inches to a foot, and terminating in a single flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The ovary is oblong and compressed, with a sessile, persistent stigma. The capsule is oblong, acute at both ends, one-celled, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-colored sap, which flows from every part when broken, but is of the deepest color in the rhizome. The bloodroot is one of the earliest and most beautiful spring flowers of the Northern United States, growing abundantly in loose, rich soils and shady situations. After the fall of the flower the leaves continue to grow, and by the middle of summer have become so large as to give the plant an entirely different aspect. Except the seeds, all parts of the plant are active.

Properties.—The following is the official description of sanguinaria: "Of horizontal growth, occasionally branching, more or less cylindrical, somewhat flattened, from 2 to 7 cm. in length, and from 5 to 15 mm. in diameter; externally dark brown, slightly annulate, with a few stem-scars on the upper surface and numerous more or less broken filiform roots and root-scars on the lower surface; fracture short and somewhat waxy, brownish-red, occasionally yellowish-white, with numerous, small, circular, yellowish fibro-vascular bundles within about 1 mm. of the epidermis, pith very large; odor slight; taste persistently acrid and bitter. Under the microscope, transverse sections of the rhizome of Sanguinaria show an outer layer of a single row of thin-walled epidermal cells; a cortex of from 10 to 15 rows of thin-walled parenchyma cells containing numerous starch grains, or a small amount of fixed oil; a zone of cambium, most of which is interfascicular; a narrow circular zone of small collateral fibro-vascular bundles, separated from each other by parenchyma; pith large, consisting of starch-bearing parenchyma cells; latex cells containing a red or orange colored secretion, either isolated or connected into irregular chains and distributed among the parenchymatous cells of the middle bark and pith; sections treated with glycerin show in the secretion cells, after twenty-four hours, spheroidal aggregates of crystals which strongly polarize light. The powder is brownish-red, sternutatory; when examined under the microscope it exhibits numerous starch grains, from 0.003 to 0.02 mm. in diameter, being mostly single, seldom 2- to 3-compound, the individual grains nearly spherical or ovoid, sometimes more or less plano-convex, somewhat resembling those of wheat starch in outline but polarizing light more strongly; numerous fragments of short latex cells with reddish-brown resinous masses; tracheal fragments few, having numerous slit-like pores." *U. S.*

For an interesting microscopical description of the rhizome by E. S. Bastin, see *Pharm.*, 1885, p. 201. Sanguinaria has a faint odor, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. Lloyd states that sanguinaria is both a contamination and an adulterant of hydrastis. (*Pharm. Rev.*, 1905, xxiii, p. 332.) It yields its virtues to water and alcohol.

Dana of New York, obtained from it an alkaloid, denominated by him *sanguinarine.* (*Ann. Lyc. of Nat. Hist., New York,* ii, 250.) It may also be conveniently procured by a process similar to that employed by Probst for obtaining chelerythrine from celandine. (*Chem. Gaz.*, i, 145.)

G. König (*A. J. P.*, 1891, p. 457) found *chelerythrine,* which is present in greatest quantity, *sanguinarine,* β- and γ-*homochelidonine,* and *protopine.* Chelerythrine crystallizes with a molecule of alcohol which is not separated at 150° C. (302° F.). Its formula is $C_{21}H_{17}O_4N$, and it is identical with the alkaloid extracted from *Chelidonium majus.* (See Part II.) The salts are lemon-yellow. Sanguinarine has the formula $C_{20}H_{15}O_4N$ (Schmidt, $C_{21}H_{15}O_4N$), and is very similar to chelerythrine in its properties. It crystallizes with one-half molecule of H_2O, and melts at 211° C. (411.8° F.). Its salts are red. The base named γ-homochelidonine is probably identical with that separated by Selle from *Chelidonium majus,* and its formula is $C_{22}H_{21}O_4N$. The fourth alkaloid, protopine, has been prepared from *Chelidonium majus,* from *Sanguinaria canadensis,* and from opium, all three of the specimens being identical. Its formula is $C_{20}H_{17}O_5N$, and it melts at 204° C. (399.2° F.). The virtues of the root are said to be rapidly deteriorated by time. Thos M. Newbold extracted from sanguinaria a non-volatile liquid acid (*sanguinarinic acid*) (*A. J. P.*, 1866, p. 496), which L. C. Hopp has shown to be a solution of impure citric and malic acids. Schlotterbeck (*Ph. Rev.*, 1900, 358) examined sanguinarine nitrate of commerce and found it to consist mainly of chelerythrine, with some sanguinarine and traces of protopine and homochelidonine; he believes that chelerythrine should be called sanguinarine. For methods of assay

of sanguinaria see *A. J. P.*, 1896, 305; *M. R.*, 1900, 451; *Proc. A. Ph. A.*, 1903, 284; *A. J. P.*, 1913, p. 395.

Uses.—Sanguinaria is an active local irritant, in large doses producing nausea and vomiting. When snuffed up the nostrils it excites much irritation and sneezing. According to the investigations of Meyer (*A. E. P. P.*, 1892, xxix, p. 397) sanguinarine is an active stimulant to the spinal cord producing in frogs strychnine-like convulsions followed, after very large doses, by complete paralysis. It also stimulates the respiratory center, increasing both the depth and rate of the breathing. By virtue of a stimulant action upon the vasomotor center it causes a rise in blood pressure which, with toxic doses, is followed by a fall in the blood pressure, due to weakening of the heart action. It also excites the flow of saliva and increases intestinal peristalsis. In toxic doses it acts as a poison to the voluntary muscles. When locally applied it causes at first pain, followed by a local anesthesia. Chelerythrine, although present in larger amounts in sanguinaria, is a much less poisonous alkaloid than sanguinarine and it is probable that it plays a rôle of relatively small importance in the action of the whole drug. It differs widely in its action from sanguinarine, acting chiefly as a paralyzant of the nerve centers, including the spinal cord, the respiratory and the vasomotor centers. It is also a poison to the voluntary muscles. It is locally irritant but has neither anesthetic nor narcotic properties. Beta-homochelidonine, the third most important alkaloid, has a feeble narcotic effect, produces cerebral convulsions, but does not increase reflex activity. It is an active local anesthetic without the irritant effect of sanguinarine.

Sanguinaria is used chiefly as an expectorant, especially in the treatment of subacute or *chronic bronchitis*. Whether it possesses any beneficial action for this purpose except that which may be attributed to its nauseating effect, seems doubtful. It has also been recommended by Graber (*J. A. M. A.*, 1907, xlix, p. 705) as a local application in chronic *eczema*, especially when secondary to *varicose ulcers*.

In toxic quantities sanguinaria produces burning in the epigastrium with vomiting, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. Twenty grains (1.3 Gm.) are said to usually act as a violent emetic. (For fatal cases, see *Am. J. M. S.*, n.s., ii, p. 506.)

The alkaloid sanguinarine has been used in doses of from one-twelfth to one-sixth of a grain (0.005–0.01 Gm.). Sanguinaria is rarely given in substance.

Dose, U. S. P., two grains (0.13 Gm.).

SANTALUM RUBRUM. U. S. (Br.)

RED SAUNDERS Santal. Rub.

(săn'tą-lŭm rŭ'brŭm)

"The heart-wood of *Pterocarpus santalinus* Linné filius (Fam. *Leguminosæ*)." *U. S.* "Red Sanders Wood is the heart-wood of Pterocarpus santalinus, *Linn. f.*" *Br.*

Pterocarpi Lignum, *Br.*, Red Sanders Wood; Lignum Santalinum Rubrum, Rasura Santalum Ligni; Red Sandal Wood; Red Santal Wood; Ruby Wood; Santal rouge, *Fr. Cod.*; Santelholz, Rothes Santelholz, *G.*; Sandalo rojo (Leno de), *Sp.*

Pterocarpus santalinus is a large tree, with alternate branches, and petiolate ternate leaves, each leaflet being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The flowers are yellow in axillary spikes, and have a papilionaceous corolla, of which the vexillum is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the alæ spreading with their edges apparently toothed, and the carina oblong, short, and somewhat inflated. The tree is a native of India, attaining the highest perfection in mountainous districts, and inhabiting especially the mountains of Coromandel and Ceylon. It is cultivated also in Southern India and in the Philippine Islands. Its wood is the official *red saunders*, though there is reason to believe that the products of other trees are also sold by the same name.

Properties.—The wood comes in heavy, irregular, roundish or angular billets of various size and thickness, externally brown from exposure, internally of a deep blood-red color, on transverse section variegated with zones of a lighter red. The structure is heavy, compact, and fibrous. In the pharmacies red saunders is usually kept in the shape of small chips, or raspings, or coarse powder, of a deep reddish-brown color, slightly astringent in taste, and when rubbed of a faint peculiar odor. It has little odor or taste. Red saunders is officially described as follows: "Usually in the form of a coarse powder, of a brownish-red or dark saffron color and nearly odorless and tasteless. Under the microscope, Red Saunders shows numerous wood-fibers which are mostly irregular in outline, with sharply pointed and occasionally forked ends, the individual fibers from 0.3 to 0.75 mm. in length, the walls being very thick, porous, yellowish, unevenly thickened, and strongly lignified, and the lumina being filled with a fine, granular, protoplasmic content; occasional tracheæ with simple or bordered pores and filled with light lemon-yellow, resinous masses; occasionally fragments showing medullary rays in narrow elliptical groups 1 cell wide and 3 to 6 cells deep; also occasional groups of crystal fibers with calcium oxalate in the form of monoclinic prisms, from 0.01 to 0.02 mm. in diameter. Mounts in hydrated chloral T.S. are of a deep, rich red color. Add 0.5 Gm. of Red Saunders to 10 mils of alcohol; the solution becomes distinctly red. Add 0.5 Gm. of Red Saunders to 10 mils of ether, the solution as-

sumes an orange-yellow color and when held in a bright light shows a distinct, greenish fluorescence. Add 0.005 Gm. of Red Saunders to 10 mils of water; the liquid remains clear and colorless. Red Saunders yields not more than 3 per cent. of ash." *U. S.*

"Imported in irregular logs or billets, freed from the pale sapwood; reddish-brown or blackish-brown externally, deep blood-red internally; hard, but easily split longitudinally. In transverse section, narrow, closely approximated, reddish medullary rays traversing a nearly black wood with scattered, large, isolated vessels. Coloring matter readily soluble in *alcohol* (90 per cent.), but almost insoluble in *water*. Odor of the warmed Wood faintly aromatic; taste very slightly astringent." *Br.*

It imparts a red color to alcohol, ether, and alkaline solutions, but not to water, and a test is thus afforded by which it may be distinguished from some other coloring woods. The alcoholic tincture produces a deep violet precipitate with ferrous sulphate, a scarlet with mercuric chloride, and a violet with the soluble salts of lead. The coloring principle, which was separated by Pelletier and called by him *santalin*, is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood, prepared with an alkaline solution. Weyermann and Haeffely have found it to possess acid properties, and give it the formula $C_{15}H_{14}O_5$. (*Ann. Ch. Ph.*, 74, p. 226.) Weidel (*Wien. Akad. Ber.*, lx, p. 388), by extracting the red saunders with potassium hydroxide, precipitating with hyrochloric acid, and again extracting from the purified precipitate with ether, obtained a colorless crystalline principle, which he calls *santal*, $C_8H_8O_3 + \frac{1}{2}H_2O$.

Cazeneuve and Hugonneng (*C. R. A. S.*, 104, 1722, 1725) have described two crystalline principles which they have extracted from red saunders, *pterocarpin*, $C_{20}H_{18}O_6$, and *homopterocarpin*, $C_{24}H_{24}O_6$, of which the former fuses at 152° C. (305.6° F.) and the latter at from 82° to 86° C. (179.6°–186.8° F.). The wood has no medicinal virtues, and is employed solely for the purpose of imparting color.

SANTONINUM. U. S., Br.

SANTONIN Santonin.

(săn-tŏ-nĭn'nŭm)

"The inner anhydride or lactone [$C_{15}H_{18}O_3 = 246.14$] of santonic acid obtained from *Artemisia pauciflora* (Ledebour) Weber (Fam. *Compositæ*). Preserve it in well-closed containers, protected from light." *U. S.* "Santonin, $C_{15}H_{18}O_3$, is a crystalline principle which may be obtained from santonica, the dried unexpanded flower-heads of Artemisia maritima, *var.* Stechmanniana, *Besser*." *Br.*

Santonine, Anhydride Santonique, *Fr. Cod.*; Santoninum, *P. G.*; Santonin, *G.*; Santonina, *It., Sp.*

The present U. S. P. and the Br. Ph. 1898 very properly omit processes for the preparation of santonin. (See U. S. D., 17th ed., 1191; also 19th ed., p. 1085.)

It has been intimated to us that the large manufacturers of santonin, abroad, first distil off from the santonica its volatile oil, which has some commercial value in Europe, and that the process for preparing santonin is probably facilitated thereby, the affinity of the oil for the santonin making the latter more difficult of purification.

Santonin was lowered in price after the erection of a factory in Tschimkent, Turkestan, where the Levant wormseed can be furnished cheaply; the process used there is to treat the wormseed with milk of lime; the calcium santoninate formed is next treated with sodium hydroxide and carbon dioxide; the sodium santonate is then decomposed by sulphuric acid. The acid liquid, on refrigeration, deposits the santonin in crystals.

Properties.—Santonin is in "colorless, shining, flattened rhombic prisms, or as a crystalline powder; odorless, and nearly tasteless at first, but afterwards developing a bitter taste; permanent in the air; it becomes yellow on exposure to light. Santonin which has become yellow may be reconverted into colorless crystals by recrystallization from alcohol. One Gm. of Santonin dissolves in 43 mils of alcohol, 1.7 mils of chloroform, and in 110 mils of ether at 25° C. (77° F.); also in 6.5 mils of boiling alcohol; very slightly soluble in water; slightly soluble in boiling water. Its solutions are neutral to litmus and are lævorotatory. It melts between 169° and 171° C. (336.2° and 339.8° F.). Heat about 0.5 Gm. of Santonin with 5 mils of alcoholic potassium hydroxide T.S.; a red color is developed. Shake about 0.01 Gm. of Santonin with a cooled mixture of 1 mil each of sulphuric acid and distilled water, heat the solution to 100° C. (212° F.), and add a minute trace of a very dilute solution of ferric chloride; a violet color results. Incinerate about 1 Gm. of Santonin; not more than 0.1 per cent. of ash remains. Two mils of sulphuric acid added to about 0.1 Gm. of Santonin produces not more than a faint, yellow color (*readily carbonizable organic impurities*). Boil about 2 Gm. of Santonin with 80 mils of distilled water and 5 mils of diluted sulphuric acid, allow the liquid to become cold and then filter it. The addition of mercuric potassium iodide T.S. or of iodine T.S. to 10 mils of the filtrate, mixed with 10 mils of distilled water, produces no cloudiness, even after standing for three hours (*alkaloids*)." *U. S.*

"Colorless, flat, rhombic prisms. Taste slightly bitter. Almost insoluble in *water;* soluble in 2.5 parts of *chloroform*, and in 50 parts of *alcohol* (90 per cent.). Melting point

170° C. (338° F). Sunlight renders it yellow. Added to warm *alcoholic solution of potassium hydroxide* it yields a violet-red color. Insoluble in diluted mineral acids. No appreciable ash." *Br.*

For a test for santonin, see *Ph. Era,* 1898, 210. The air has no effect upon it, but it becomes yellow on exposure to sunlight. According to Sestini, the santonin is changed, through the influence of light, into formic acid, and an uncrystallizable substance, much more soluble in alcohol and ether than santonin itself, which he calls *photosantonic acid,* $C_{15}H_{22}O_5$, and a red resinous substance. If the santonin be in alcoholic solution, after several months of exposure to sunlight it is changed into the ethyl ether of photosantonic acid. In its relations to polarized light it is very strongly lævogyrate, and retains this property with acids, though losing it entirely when combined with salifiable bases. (Buignet, *J. P. C.,* Janv., 1862, p. 26.)

When warmed with alkalies, santonin is changed into monobasic *santoninic acid,* $C_{15}H_{20}O_4$, while concentrated baryta water changes it on prolonged boiling into the isomeric *santonic acid.* Schmidt (*J. P. C.,* 4e sér., iii, 394) disproved the previously accepted statement that santonin was a glucoside; but Hesse (*Ber. d. Chem. Ges.,* vi, 1280) stated santonin to be the anhydride of *santoninic acid,* and prepared this acid by adding an excess of diluted hydrochloric acid to an aqueous solution of the sodium salt, and adding ether, from which the acid may be recovered by evaporation. When santoninic acid is heated to 120° C. (248° F.), it is resolved into santonin and water. It has a strongly acid reaction, and decomposes sodium and calcium carbonate.

Sodium santoninate (*Sodii Santoninas*) was official in the *Pharmacopœia Germanica* of 1872, and was recognized in the U. S. P. 1880. It is a colorless crystalline substance freely soluble in water. It was very properly dropped at the U. S. P. 1890 revision, because it is more easily absorbed than santonin in crystals, and therefore much more dangerous to the patient and much less destructive to *intestinal worms.* For method of preparation and tests of purity, see U. S. D., 19th ed., p. 1243.

For a history with a review of the chemical constituents and decomposition products of santonin see *Y. B. P.,* 1901, 487. Santonin is now considered to be the inner anhydride or lactone of santonic acid.

Cannizzaro and Carnelutti (*Ber. d. Chem. Ges.,* xvi, 2685) have shown that santonic acid breaks up on high heating into *propionic acid,* $C_3H_6O_2$, and *dihydrodimethylnaphthol,* $C_{10}H_7(CH_3)_2.OH$, and distilled over zinc dust it gives a mixture of dimethylnaphthol, $C_{10}H_5(CH_3)_2.OH$, dimethylnaphthalene, $C_{10}H_6(CH_3)_2$, and propylene. *Santonone,* $(C_{15}H_{17}O_2)_2$, a decomposition product of santonin, is made by gradually adding zinc dust to a hot solution of santonin in acetic acid, preferably in the presence of a little platinum tetrachloride. It forms silky white needles, is very soluble in benzene, less so in hot alcohol, ether or diluted acetic acid, and insoluble in water.

Uses.—Santonin is used chiefly as a vermifuge. Against the *round worm* it is generally esteemed as one of the most efficient remedies we possess, its ease of administration as well as its certainty of action making it peculiarly valuable. The coarse crystals should be preferred to the powder as being less readily dissolved, and therefore less likely to be absorbed from the stomach. It may be well administered to children in the form of lozenges made with sugar and tragacanth (for formula, see *A. J. P.,* vi, 124), which if the unbroken crystals are used, can be rendered very pleasant to the taste, so that children will eat them as candy. The dose of santonin for a child two years old is from one-fourth to one-half grain (0.016–0.032 Gm.). To older patients it is best given by enclosing in gelatin capsules. It should always be followed by a cathartic, calomel being perhaps best; although castor oil is sometimes used it should be avoided as likely to increase the absorption. The santoninates or any combination of santonin with alkali carbonates or hydroxides, should be sedulously avoided as vermifuges because of the liability of their being absorbed.

Santonin has been recommended internally in a large variety of conditions, but has failed to establish itself in any of them. It was at one time used as a stimulant to the optic nerve in *amaurosis,* especially due to *nicotinism.* Drake (*S. M.,* 1907, p. 550), reports favorably on its use in *dysentery,* and Negro has used it as an analgesic in *tabes* and various forms of *neuralgia.* The statements of Sejournet that it would diminish the output of sugar in *diabetes* have been contradicted by the observations of Walterhoefer. (*B. K. W.,* 1911).

According to Walter G. Smith, the yellow color imparted to urine by santonin is distinguished from that produced by other substances by becoming purplish-red on the addition of ammonia or other alkali. (*P. J.,* Dec., 1870, p. 528.) For researches upon the character of the urinary coloring matter, consult the same paper.

In overdose santonin produces a poisoning whose symptoms are giddiness, mental apathy or stupor, great paleness and coldness of the surface, vomiting, profuse sweating, trembling, mydriasis, and finally loss of consciousness, with convulsions, often violent and accompanied by opisthotonos and emprosthotonos and failure of respiration. Xanthopsia is an early and characteristic symptom. All objects appear discolored, generally yellow, but frequently green, and sometimes blue. At the same time the urine is tinged of a yellow or a green color. These effects were formerly thought to be due to the staining of the aqueous humor but are more probably to be attributed to a direct action on the retina. In regard to the minimum fatal dose, two grains are said to have killed a feeble child five years old, and one six or seven years old is said to have suffered death from six grains

after development of hæmaturia (*B. G. T.*, lxxiv, 362); four grains produced very serious symptoms in a child four years old. (*P. J.*, ix, 696.) The xanthopsia and discolored urine make the diagnosis of santonin poisoning easy. According to Crouzel the addition of alkalies to the urine will demonstrate the presence of santonin, before the coloration is pronounced, by the development of a characteristic carmine-red tint.

Dose, two to four grains (0.13–0.26 Gm.).

SAPO. U. S. (Br.)

SOAP [White Castile Soap]

(sā'pō)

"Soap prepared from olive oil and sodium hydroxide. Preserve dried or powdered Soap in well-closed containers." *U. S.* "Hard Soap is soap made from sodium hydroxide and olive oil; it contains not more than 30 per cent. of water." *Br.*

Sapo Durus, *Br.*; Hard Soap, Castile Soap; Savon medicinal, *Fr. Cod.*; Savon amygdalin, Savon blanc, Savon d'Espagne, *Fr.*; Sapo medicatus, *P. G.*; Medizinische Seife, Oel-Sodaseife, Seife, Spanische Seife, *G.*; Sapone medicinale, S. amigdalino, Sapone duro, *It.*; Jabon de aceite de olivas, Jabon, *Sp.*

Soaps embrace all those compounds which result from the reaction of salifiable bases with fats and oils. Fats and oils, as has been explained under the titles *Adeps* and *Olea*, consist generally of three glyceryl esters, two solid, differing in fusibility, called *stearin* and *palmitin*, and one liquid, called *olein*. Stearin is found most abundantly in fats which are firm and solid, as suet and tallow, and palmitin and olein in the oils. When the fats and oils undergo *saponification* by reaction with a salifiable base, these three esters are decomposed into fatty acids peculiar to each, discovered by Chevreul, and called stearic, palmitic, and oleic acids, which unite with the base to form the soap, and into glycerin (glycerol), which is set free. Hence it follows that stearin is a stearate of glyceryl, C_3H_5, the radical of the triatomic alcohol glycerol, $C_3H_5(OH)_3$, palmitin a palmitate, and olein an oleate, and that the fats and oils are mixtures of these three fatty salts. Hence, also, it is obvious that soaps are mixed stearates, palmitates, and oleates of certain bases.

Stearic acid, $C_{18}H_{36}O_2$, is a firm white solid, like wax, fusible at 69.2° C. (157° F.), greasy to the touch, pulverizable, soluble in alcohol, very soluble in ether, but insoluble in water. In the impure state it is used as a substitute for wax in making wax candles. *Palmitic acid*, $C_{16}H_{32}O_2$, forms a white scaly mass, and melts at 62° C. (143.6° F.). *Oleic acid*, $C_{18}H_{34}O_2$, is an oily liquid, insoluble in water, soluble in alcohol and ether, lighter than water, crystallizable in needles, a little below 0° C. (32° F.), and having a slight odor and a pungent taste. (See *Acidum Oleicum.*) *Glycerin* is described under a separate head. (See *Glycerinum.*)

Soaps are divided into the soluble and the insoluble. The soluble soaps are combinations of the fatty acids with sodium, potassium or ammonium hydroxides; the insoluble consist of the same acids united with earths or metallic oxides. It is the soluble soaps only that are detergent, and to which the name *soap* is usually applied. Several of the insoluble soaps are employed in pharmacy, as, for example, the lead monoxide soap, or lead plaster, and the lime soap, or lime liniment. (See *Emplastrum Plumbi* and *Linimentum Calcis.*) The two official soaps are of the soluble kind. One is a soda soap, made with olive oil (Castile soap), the other a potassium soap (soft soap). (See *Sapo Mollis.*) The soap of ammonia is noticed elsewhere. (See *Linimentum Ammoniæ.*)

The consistence of the fixed alkaline soaps depends partly on the nature of the oil or fat, and partly on the alkali present. Soaps are harder the more stearate and palmitate they contain, and softer when the oleate predominates, and, as regards the alkali present, they are harder when formed with sodium hydroxide, and softer when containing potassium hydroxide. Hence it is that of pure soaps, considered as salts, sodium stearate is the hardest and least soluble, and potassium oleate the softest and most soluble.

Liquid soaps are largely coming into use as economical and sanitary substitutes for soap in public lavatories. Several good formulas have been proposed by E. R. Jones (*J. A. Ph. A.*, 1914, 1537) for use with soft, medium and hard waters, respectively.

Preparation.—The following is an outline of the process for making soap. The oil or fat is boiled with a solution of caustic alkali, beginning with a weak solution, and as saponification proceeds using a stronger lye until the whole forms a thick mass, which can be drawn out into long clear threads. After the soap is completely formed, the next step is to separate it from the excess of alkali, the glycerin, and the redundant water. This is effected by adding common salt, or a very strong alkaline lye, in either of which the soap is insoluble. The same end may be attained by boiling down the solution until the excess of the alkali forms a strong alkaline solution, which acts the same part in separating the soap as the addition of a similar solution. As soon as the soap is completely separated, it rises to the surface, and, when it has ceased to froth in boiling, it is ladled out into wooden frames to congeal, after which it is cut into bars by means of a wire. The soap, as first separated, is called *grain soap*. It may be purified by dissolving it in an alkaline lye and separating it by common salt. During this process the impurities subside, and the soap combines with more water, and hence it becomes weaker, although purer and whiter. If the grain soap be not purified, it will form *marbled soap*—the colored streaks arising principally from an insoluble soap of

oxidized iron. Sometimes the marbled appearance is produced by adding to the soap, as soon as it is completely separated, a fresh portion of lye, and immediately afterwards a solution of ferrous sulphate. The greenish-black ferrous hydroxide is precipitated, and gives rise to dark-colored streaks, which, by exposure to the air, become red in consequence of the conversion of the black hydroxide into the ferric hydroxide.

When commercial toilet soap is required, the *grained* soap, or, as it is sometimes called, *boiled* soap, is often remelted, perfumed, and worked over by the process of *milling, plotting,* and *moulding,* whereby the soap is brought into the desired shape for popular use. The *cold process* is also used, and is preferred by many because of its simplicity and economy. The following (from Sadtler's *Industrial Organic Chemistry,* 1906, 64) gives the outlines of the process. The so-called "cold process" requires the use of exact weights of well-refined fats and of caustic soda of a given specific gravity (from 32° to 36° B.), the quantities being such that only just enough soda is present to completely saponify the fat. The materials are allowed to stand together for a short time and then thoroughly mixed in a kettle provided with steam agitating paddles, and kept at a temperature of not over 48.9° C. (120° F.). The reaction proceeds rapidly, and after some fifteen minutes the materials have so far united that they will not separate on standing, although the complete saponification of the charge may require days. They are then run out into the cooling frames. It is obvious that soaps made in this way retain all the glycerin originally combined with the fatty acids disseminated through the particles of soap, and belong to the class of "filled" or "padded" soaps. When cocoanut oil alone is used, the temperature of working in this cold process need not be higher than 23.9° C. (75° F.) in summer and 32.2° C. (90° F.) in winter; if one-half tallow, from 40° to 42.2° C. (104°–108° F.), and if two-thirds tallow, from 45° to 48.9° C. (113°–120° F.) is necessary. A well-refined tallow can be saponified in this way, too, and rosin may be added. For a practical process for making soap in small quantities without boiling, see *U. S. D.,* 19th edition, page 1089.

The official *soap* (*Sapo,* U. S.; *Sapo Durus,* Br.) is an olive oil soda soap, made on the same general plan as that just explained.

Common soap is also a soda soap; but instead of olive oil it contains solid animal fats. This soap corresponds with the white soap of northern European countries and of the United States, and is formed usually from barilla and tallow. In Scotland it was formerly manufactured from kelp and tallow. It was introduced into the U. S. Pharmacopœia of 1860 as the only proper soap for making opodeldoc; but, as this preparation was discarded, this variety of soap was dismissed along with it.

Besides the official soaps of the U. S. and Br. Pharmacopœias, there are many other varieties, more or less used for medicinal or economical purposes. *Starkey's soap* is prepared by uniting, by trituration, equal parts of potassium carbonate, oil of turpentine, and Venice turpentine. *Beef marrow soap* is a fine animal oil soap, also included in the French standard. *Windsor soap* is a scented soda soap, made of one part of olive oil and nine parts of tallow. *Eau de luce* (*aqua luciæ*) is a kind of liquid soap, formed by mixing a tincture of oil of amber and balsam of Gilead with ammonia water. *Transparent soap* is prepared by saponifying kidney fat with soda free from foreign salts, drying the resulting soap, dissolving it in alcohol, filtering and evaporating the solution, and running it into moulds when sufficiently concentrated. The soap is yellow or yellowish-brown, and preserves its transparency after desiccation. Harding (*Proc. Minn. Pharm. Assoc.,* 1896, 116) states that sugar is used in soap to give it transparency and sodium carbonate to give firmness. The German transparent soap always contains a large quantity of cocoanut-oil soap. Modern transparent soaps owe their transparency usually to their having been made into an alcoholic solution and then the alcohol carefully recovered, which leaves the mass transparent. Cheap grades of transparent soaps often owe this property to the presence of sugar which communicates the desired property when present to the extent of 5 or 10 per cent. *Palm soap* is prepared from sodium hydroxide and palm oil, to which tallow is added to increase its firmness. If it be wanted white, the palm oil may be bleached by heat, potassium dichromate with sulphuric acid, chlorine, or exposure to the sun. This soap has a yellowish color, and the agreeable odor of violets derived from the oil. *Soap balls* are prepared by dissolving soap in a little water and then forming it with starch into a mass of the proper consistence. *Common yellow soap* (*rosin soap*) derives its peculiarities from an admixture of rosin and a little palm oil with the tallow employed, the oil being added to improve its color. Sodium silicate has to some extent been substituted for rosin, as more economical. (*A. J. P.,* 1863, p. 466.) Large quantities of lard oil (nearly pure olein) are manufactured into soap.

All the varieties of soap are now manufactured in the United States. Large amounts of olive oil soaps and very fine toilet soaps are, however, imported from France, Italy, and Spain.

Properties.—Soap, whatever may be its variety, has the same general properties. Its aspect and consistence are familiar to every one. Its odor is peculiar, and its taste slightly alkaline. It is usually somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It is soluble in water, and more readily in hot than in cold. Potassa soaps and those containing oleic acid are far more soluble than the soda soaps, especially those in which the stearates and palmitates predominate. Acids

added to an aqueous solution of soap combine with the alkali, and set free the oily acids, which, being diffused through the water, give it a milky appearance. Its decomposition is also produced by metallic salts, which invariably give rise to insoluble soaps. Soap is soluble in cold and abundantly in boiling alcohol. This solution constitutes the *tincture of soap,* and forms a very convenient test for discovering lime in natural waters. As the tincture sometimes gelatinizes, it is proposed by Bjorklund to remedy this inconvenience by employing soap in the undried state, that is, containing a large proportion of water. (*J. P. C.*, 4e sér., ii, 179, 1865.) The efficacy of soap as a detergent depends upon its hydrolytic decomposition when in solution, whereby alkali is liberated which saponifies and emulsifies grease and fatty substances rendering them readily removable in the washing processes. The chief adulterations in soap are lime, silica, gypsum, heavy spar, steatite, pipe-clay, and sodium sulphate. When adulterated with these substances, it will not be entirely soluble in alcohol. According to Riegel, glue is an occasional adulteration in Spanish soap, discoverable also by its insolubility in alcohol. The same impurity is sometimes found in other soaps. Soap is officially described as "a white or whitish solid, in the form of bars, hard, yet easily cut when fresh, or as a fine, yellowish-white powder, having a faint, peculiar odor, free from rancidity, and a disagreeable, alkaline taste. It is soluble in water and in alcohol, more readily, however, with the aid of heat. Its aqueous solution is alkaline to litmus. Dissolve about 0.5 Gm. of Soap, accurately weighed, in 10 mils of alcohol, evaporate the mixture to dryness in a tared beaker containing 1 Gm. of clean sand, which has been previously dried at 110° C. (230° F.). Dry the residue at 110° C. (230° F.) to constant weight. The loss does not exceed 36 per cent. for unpowdered Soap or 10 per cent. for powdered Soap (*water*). A solution of a quantity of Soap corresponding to 0.64 Gm. of dried Soap in 25 mils of hot alcohol does not gelatinize on cooling to 20° C. (68° F.) (*soap from animal fats*). Ten mils of an aqueous solution of Soap (1 in 20) remains unchanged in color upon the addition of ammonium sulphide T.S., and upon acidulating another portion of 10 mils of the solution with hydrochloric acid and filtering, the filtrate remains unchanged in color when an equal volume of hydrogen sulphide T.S. is added and the mixture allowed to stand well-stoppered, in a warm place, for half an hour (*metallic impurities*). Dissolve about 10 Gm. of Soap, accurately weighed, in 100 mils of alcohol, with the aid of heat. Transfer the undissolved residue, if any, to a tared filter which has been dried at 100° C. (212° F.), and wash it thoroughly with boiling alcohol. Its weight, after drying at 100° C. (212° F.), does not exceed 1 per cent. of the weight of dry Soap in the original weight taken (*sodium chloride, sodium carbonate, silica*). The weight of this residue, thoroughly washed with distilled water and dried at 100° C. (212° F.) does not exceed 0.15 per cent. of the weight of dry Soap in the original weight taken (*silica and other accidental impurities*). The alcoholic filtrate and washings from the preceding test are not reddened by 3 drops of phenolphthalein T.S. (*sodium hydroxide*). Dissolve about 10 Gm. of Soap in 200 mils of hot distilled water, add 2 drops of methyl orange T.S. and then diluted sulphuric acid with constant stirring until the aqueous layer becomes red. Boil the mixture until the supernatant layer of the fatty acids is clear and free from solid particles. Separate the aqueous layer with the aid of a siphon and wash the fatty acids by decantation with hot distilled water, until 10 mils of the washings, acidulated with a drop of hydrochloric acid, no longer gives a precipitate on the addition of barium chloride T.S. Now place the dish containing the fatty acids on a water bath and heat until the fatty acids are completely liquefied, then filter the warm acids through a dry filter in a hot-water funnel into a flat dish and dry the acids over sulphuric acid. The iodine number of the acids thus obtained is not less than 84 nor more than 90 (see Part III, Test No. 8)." *U. S.*

"Greyish-white, yellowish-white, or greenish-white; becoming horny and pulverisable when dried. Nearly inodorous. Soluble in 20 parts of cold *water,* and in 1.5 parts of hot *water;* soluble in *alcohol* (90 per cent.), more readily when warmed. Responds to the tests for alkaline hydroxides and carbonates and for free fatty acids described under 'Sapo Animalis.' Does not impart a greasy stain to white unglazed paper (absence of free oil). Loses not more than 30 per cent. of its weight when dried at 110° C. (230° F.). Ash not deliquescent (absence of potassium soap). The absence of fatty acids derived from oils other than Olive Oil is determined by the following process:—Dissolve the Soap in hot *water,* add a slight excess of *hydrochloric acid* and heat on a water-bath until the liberated fatty acids form a transparent layer. Separate the fatty acids on a wet filter-paper, and wash with hot *water* until the washings are neutral to *solution of methyl orange.* Filter the oily layer through a dry filter paper in a warm oven. The fatty acids thus separated possess the following characters:—*Iodine value,* 83 to 92; *acid value,* 195 to 205; melting point, 21° to 28° C. (69.8°–82.4° F.); *refractive index* at 40° C. (104° F.), 1.4540 to 1.4580." *Br.*

Olive oil soda soap (Sapo), otherwise called *Castile* or *Spanish soap,* is a hard soap, and is presented under two principal varieties, the white and the marbled. *White Castile soap,* when good, is of a pale yellowish-white color, incapable of giving an oily stain to paper, devoid of rancid odor or strong alkaline qualities, and entirely soluble both in water and in alcohol. It should not feel greasy, nor grow moist, but, on the contrary, should become dry by exposure to the air, without exhibiting any saline efflorescence. This variety of soap contains about 21 per cent. of water. Sometimes it contains a larger proportion of water, with which the soap

is made to combine by the manufacturer, with the fraudulent intention of increasing its weight. Soap thus adulterated is known by its unusual whiteness, and by its suffering a great loss of weight in a dry air. The proportion of water may be ascertained by introducing the soap into a saturated solution of sodium chloride, and boiling, when the soap, nearly free from water, concretes into a solid mass. A more satisfactory method is to evaporate a carefully weighed portion, which has been reduced to fine particles, to a constant weight, upon a water bath. *Marbled Castile soap* is harder, more alkaline, and more constant in its composition than the other variety. It contains about 14 per cent. of water. Having less water than the white Castile, it is a stronger and more economical soap, but at the same time is less pure. The impurity arises from the veins of marbling, consisting of ferruginous matters, as already explained, and from various substances added as make-weights. Soap made with animal fat, with the probable addition of sodium silicate, has been sold for Castile soap. The Italian brands of Castile soap which have been so largely used in past years are rapidly depreciating in quality; they are now chiefly made from cotton seed oil and other substitutes for olive oil. Floating soaps owe their distinctive property in this respect to having been beaten while cooling so as to include innumerable small air bubbles which give the buoyancy to the soap.

Animal oil soda soap (*Sapo Vulgaris*) is a hard soap, of a white color, inclining to yellow. It is made from tallow and sodium hydroxide. This soap possesses the same general properties as the olive oil soda soap.

Composition.—It has been already explained that soap consists of certain fatty acids united with an alkali. As olive oil is a compound of olein with palmitin and small quantities of the esters of other fatty acids, so the official "soap" is a mixed sodium oleate and palmitate. The former official "common soap" is principally a sodium stearate, and "soft soap," as defined in the Br. Pharmacopœia, is a mixed potassium palmitate and oleate.

Incompatibles.—Soap is decomposed by all the acids, earths, and earthy and metallic salts. Acids combine with the alkali, and set free the fatty acids of the soap; the earths unite with the fatty acids, and separate the alkali, while the earthy and metallic salts give rise, by double decomposition, to an insoluble soap of their base and a saline combination between their acid and the alkali of the soap. Hard waters, in consequence of their containing salts of lime, decompose and curdle soap. They may be rendered soft, and fit for washing, by adding alkali carbonates, hydroxides or borates.

Uses.—Soap is laxative and antacid. It acts like an alkaline base and was formerly used to some extent internally, but has been entirely superseded by more elegant alkaline compounds, except in laxative preparations. In *constipation,* particularly when arising from hardened fæces in the rectum, a strong solution of soap, especially of soft soap, forms a useful enema. When the latter is used, two tablespoonfuls may be dissolved in a pint of warm water. Externally soap is used in various *skin diseases,* not merely for its detergent effect, but also to soften the horny layer of the epiderm. In pharmacy, soap is frequently employed for the purpose of giving a proper consistence to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It is an excellent emulsifying agent when the mixture is intended for external use. It is also an ingredient in some liniments and plasters. In toxicology it is used as a chemical antidote for the mineral acids and the caustic salts of iron, and should always be resorted to in poisoning by these agents, without a moment's delay, and its use continued until magnesia, chalk, or sodium or potassium bicarbonate can be obtained. The mode of administration in these cases, is to give a teacupful of a strong solution of soap every three of four minutes, until the patient has taken as much as he can swallow.

Dose, five grains to half a drachm (0.32–2.0 Gm.), given in pill.

SAPO ANIMALIS. Br.

CURD SOAP

(sā'pō ăn-ĭ-mā'lĭs)

"Curd Soap is soap made from sodium hydroxide and purified animal fats consisting principally of stearin; it contains not more than 30 per cent. of water." *Br.*

Sapo Sebacinus; Sapo domesticus; Animal Soap, Tallow Soap, Stearin Soap; Savon animal, *Fr. Cod.;* Hausseife, Talgseife, Stearinseife, *G.;* Sapone animale, *It.;* Jabon animal, *Sp.*

The British Pharmacopœia, 1914, has retained curd soap in its list, and thus describes it: "Yellowish-white or greyish-white; nearly inodorous; easily moulded when heated, becoming horny and pulverisable when dried. Sparingly soluble in cold *water;* completely soluble in hot *water;* soluble in *alcohol* (90 per cent.). When 5 grammes of the dried and powdered Soap are dissolved in 50 millilitres of boiling *alcohol* (90 per cent.), and the solution filtered while hot, the filter being thoroughly washed with more of the boiling *alcohol,* the filtrate is neutral to *solution of phenolphthalein* (absence of alkaline hydroxides and free fatty acids), and if the filter is then washed with hot *water,* the washings require for neutralisation not more than 5 millilitres of *N/10 solution of sulphuric acid, solution of methyl orange* being used as indicator (limit of alkaline carbonates). Does not impart a greasy stain to white unglazed paper (absence of free fats). Loses not more than 30 per cent. of its weight when dried at 110° C. (230° F.). Ash not deliquescent (absence of potassium soap)." *Br.*

Soap made from animal oils and fats is very largely used for all domestic purposes; it was long used for making *solid opodeldoc*, but is now replaced by sodium stearate. (See *Linimentum Saponato-Camphoratum*, N. F., Part III.)

SAPO MOLLIS. U. S., Br.

SOFT SOAP Sapo Moll. [Green Soap]
(sā'pō mŏl-lĭs)

"Soft Soap is soap made from potassium hydroxide and olive oil." *Br.*

Sapo Viridis, U. S. P. 1880; Savon mou, Savon vert, Savon à Base de Potasse, *Fr.*; Sapo Kalinus, *P. G.*; Kaliseife, Schmierseife, *G.*; Sapone di potassa, *It.*

* "Cottonseed Oil, *four hundred and thirty grammes* [or 15 ounces av., 73 grains]; Potassium Hydroxide, *eighty-six grammes* [or 3 ounces av., 15 grains]; Alcohol, *fifty milliliters* [or 1 fluidounce, 331 minims]; Water, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve *eighty-six grammes* [or 3 ounces av., 15 grains] of potassium hydroxide in *one hundred mils* [or 3 fluidounces, 183 minims] of water in a tared, capacious dish with the aid of heat. Immediately add *four hundred and thirty grammes* [or 15 ounces av., 73 grains] of cottonseed oil to the hot solution and stir the mixture actively for a few moments. Then reapply the heat and, at the first evidence of froth from boiling, pour in the *fifty mils* [or 1 fluidounce, 331 minims] of alcohol, stir it actively until the froth suddenly rises, then withdraw the heat and again stir until the Soap assumes the consistence of a paste. Now determine by the method given below whether the product will contain the required excess of potassium hydroxide when water is added to make *one thousand grammes* [or 35 ounces av., 120 grains]. If the product does not meet the requirements of this test, add more potassium hydroxide or cottonseed oil as may be needed and again heat it until the saponification is complete. Finally add enough water to make the finished product weigh *one thousand grammes* [or 35 ounces av., 120 grains] and warm it gently, stirring carefully, until the water is all absorbed and a clear soap results. The potassium hydroxide used in this process should be of the full strength directed by the Pharmacopœia (85 per cent.). Potassium hydroxide of any other strength, however, may be used, if a proportionally larger or smaller quantity is taken, the proper amount for the above formula being ascertained by dividing 7310 by the percentage of KOH contained therein." *U. S.*

Cottonseed oil is used in the U. S. P. IX in place of linseed oil, which was used in the preparation of soft soap in the U. S. P. VIII. The change is believed to be an improvement. A soft soap process was first introduced into the U. S. P., 1890, with the view of affording a soft soap for medicinal purposes which shall be of uniform strength. Domestic *soft soap* is prepared on the same general principles as hard soap, potassium hydroxide being employed as the alkali, and a fatty matter, rich in olein, as the oil. The French soft soap is made with the seed oils, such as rape seed, hemp seed, etc.; the Scotch and Irish, with fish oil and some tallow, and our own, with refuse fat and grease. A lye of wood ashes is the form of potassium usually employed. In forming this soap it is necessary that it should continue dissolved in the alkaline solution, instead of being separated from it. Hence soft soap is a potassium soap completely dissolved in the solution of its alkali, which is present in excess. As made in this country, it is usually semi-fluid, slippery, capable of being poured from one vessel to another, and of a dirty brownish-yellow color and varying strength.

Properties.—It is officially described as "a soft, unctuous, yellowish-white to brownish-yellow mass, having a slight, characteristic odor and an alkaline taste. An aqueous solution of Soft Soap is alkaline to litmus and phenolphthalein T.S.; a solution in hot distilled water (1 in 20) is nearly clear. Dissolve about 5 Gm. of Soft Soap, accurately weighed, in 100 mils of hot alcohol, collect the residue, if any, on a filter, thoroughly wash it with hot alcohol, and dry it to a constant weight at 100° C. (212° F.). The weight of the residue does not exceed 3 per cent. of the weight of Soap taken. The combined filtrate and washings, on the addition of 0.5 mil of phenolphthalein T.S. and titration with tenth-normal sulphuric acid V.S., shows not less than 0.1 per cent. nor more than 0.25 per cent. of KOH. Each mil of tenth-normal sulphuric acid V.S. used corresponds to 0.00561 Gm. of KOH. Soft soap loses not more than 52 per cent. in weight, when tested for water as directed under *Sapo*." *U. S.*

"Yellowish-white to green; of an unctuous consistence. Nearly inodorous. Readily soluble in *alcohol* (90 per cent.), leaving not more than 3 per cent. of insoluble residue. Responds to the tests for alkaline hydroxides and carbonates and for free fatty acids described under 'Sapo Animalis.' Does not impart a greasy stain to white unglazed paper (absence of free oil). Ash very deliquescent, and yields no characteristic *reactions* for copper. The mixed fatty acids, liberated and treated as described under 'Sapo Durus,' possess the characters there specified." *Br.*

For more than one hundred years, under the name of "*green soap*," there has been used in Europe a soap made by saponifying linseed, rape seed, or other vegetable oils with various refuse oils, usually including fish oils, an excess of potassium hydroxide, and a little sodium hydroxide. The green color of this soap was probably due to the presence of chlorophyll in the impure vegetable oils used. This green soap, or so-called "German soap," was formerly imported into America, but at present has been almost entirely superseded by soft soap made in this country, from which it does

not differ in the nature of its active constituents or in its therapeutic properties.

If a green soap be wanted, it may be made by the process given in the *U. S. D.*, 19th edition, p. 1093. The soft soap of France, formerly the *savon vert* of the French Codex, has a greenish color, and usually the consistence of a soft ointment. It is made of hemp seed oil, or sometimes of the dregs of olive oil, and potassium hydroxide. G. M. Beringer (*Proc. A. Ph. A.*, 1903, 420) prefers to use Malaga olive oil in making green soap, and M. I. Wilbert (*Proc. A. Ph. A.*, 1904, 228) extracts the green coloring matter from hemp seed by macerating 25 parts of ground hemp seed with alcohol and obtains 100 parts of a tincture; by substituting an equal measure of this tincture for the quantity of alcohol used in the official process, a green soap can be made, which will have the color which is regarded by some as a very important characteristic.

Uses.—Soft soap possesses not only the detergent properties of neutral soaps, but because of the excess of alkali has active medical virtues, especially as a topical remedy. In the first place it removes the fat more thoroughly from the skin and is therefore of service in those forms of *skin diseases* accompanied with disturbances of sebaceous secretion, such as *seborrhea* or *comedo*. It has also the property of softening the keratin elements of the epiderm, and is therefore useful in conditions accompanied with crusts and scales, such as *psoriasis* and *chronic eczema*. Because of its local irritating action it may also be used as a stimulant in *acne vulgaris* and *rosaceæ*. It is also asserted to be of adjuvant service in the treatment of various parasitic skin diseases.

Kappesser (*Fort. Med.*, 1912) has reported favorable results from the use of inunctions of one-half to one drachm (2–3.9 Gm.) of soft soap in *scrofulous lymphadenitis*. Kuelbes (*Th. M.*, 1914, xxviii) has found it of occasional benefit also in a large variety of other conditions, especially *cardiac neuroses* and *migraine*. In *chronic bronchitis* and *dyspepsia* he asserts the inunctions often improve the general condition of the patient, but in *asthma* they usually were without influence.

SAPPAN. Br.

SAPPAN

(săp′pạn)

"Sappan is the heart-wood of Cæsalpinia Sappan, *Linn.*" *Br.*

Sappan wood, Sampfen wood, Bakam, Tairi, Patang, Teri, Versino, *It.*; False Sandalwood, Indian Redwood, Samfen.

Cæsalpinia Sappan is a small thorny tree indigenous to the Eastern and Western Asiatic Peninsulas, Pegu and Tenasserim, and is also cultivated in Central India. The leaves are large and abruptly bi-pinnate; the flowers being yellow and in axillary racemes; and the pods are oblong, flattened, nearly smooth and dehiscent or indehiscent. The wood yields a valuable red dye which is also prepared from the pods and from the bark. The commercial samples vary considerably. There are two commercial varieties, viz., (1) Singapore or Dhansari, and (2) Ceylon sappan, the former being preferred. According to Dymock, the freshly cut wood is whitish, but becomes red on exposure to the air. He also states that the addition of alkalies increases the yield of coloring matter, turning it a reddish-violet. According to the British Pharmacopœia, it occurs in "hard, heavy pieces of variable size, or in orange-red chips. In transverse section, well-marked concentric rings, numerous narrow medullary rays, and large vessels. No odor; taste slightly astringent. It communicates to *alcohol* (90 per cent.) and to *water* a red color, which becomes carmine-red, but not purple, upon the addition of *solution of sodium hydroxide* (distinction from Logwood)." *Br.*

According to the investigations of Bolley, sappan wood contains *brasilin*, $C_{16}H_{14}O_5$, identical with that of Brazil wood.

Sappan, or samfen, as it is sometimes called, has been an article of commerce for at least five hundred years. It is employed in the arts as a substitute for logwood in dyeing. Medicinally it is used as an astringent in the treatment of *diarrhea*. It may be given in the form of a decoction.

Dose, from fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Decoctum Sappan, *Br.*

SARSAPARILLA. U. S.

SARSAPARILLA Sarsap.

(sär-sạ-pạ-rĭl′lạ)

"The dried root of *Smilax medica* Chamisso and Schlechtendal, known in commerce as Mexican Sarsaparilla; or *Smilax officinalis* Kunth, or an undetermined species of *Smilax*, known in commerce as Honduras Sarsaparilla; or *Smilax ornata* Hooker filius, known in commerce as Jamaica Sarsaparilla (Fam. *Liliaceæ*)." *U. S.* "The dried root of Smilax ornata, *Hook. f.* Imported from Costa Rica and commonly known as Jamaica sarsaparilla." *Br.* 1898.

Sarsæ Radix, *Br.* 1898; Jamaica Sarsaparilla; Salsepareille, *Fr. Cod.*; Radix Sarsaparillæ, *P. G.*; Sarsaparille, Sarsaparilla, *G.*; Salsapariglia, *It.*; Zarzaparrilla (Raiz de), *Sp.*

The medicinal species of smilax grow in Mexico, Guatemala, and the warm latitudes of South America. The roots are very long and slender, and originate in great numbers from a common head or rhizome, from which the stems of the plant rise. The whole root with the rhizome is usually dug up, and as brought into market exhibits not unfrequently portions of the stems attached, sometimes several inches in length. The commercial sarsaparillas are conveniently divided into the mealy and non-mealy

sarsaparillas. The first class comprises especially the Honduras, Guatemala, and Brazilian varieties; the second the Jamaica, Mexican and Guayaquil sarsaparillas. A very convenient key for distinguishing the commercial sarsaparillas by certain anatomical characters has been devised by Luerssen in his *Handbuch der Medicinpharm. Botanik,* ii, 404.

All the species of Smilax are climbing or trailing plants, with prickly stems—a character expressed in the name of the medicine, which is derived from two Spanish words (*zarza parilla*), signifiying a small thorny vine.

The official species of smilax are as follows:

S. medica has an angular stem, armed with straight prickles at the joints, and a few hooked ones in the intervals. The leaves are smooth, bright green on both sides, shortly acuminate, five-nerved, with the veins prominent beneath. They vary much in form, the lower being cordate, auriculate-hastate, the upper cordate-ovate. In the old leaves the petiole and midrib are armed with straight subulate prickles. The inflorescence is an umbel of from eight to twelve flowers, with a smooth axillary peduncle and pedicels about three lines long.

The *Mexican* or *Vera Cruz sarsaparilla* is derived from this species. Although sometimes in bundles, it commonly comes in large, rather loose bales, weighing about two hundred pounds, bound with cords or leather thongs, and usually containing the roots folded upon themselves, and separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much coiled with earth. It contains but little starch and has quadrangular endodermal cells, with thickened walls, and more or less oval lumen. It was formerly little esteemed; but, from the acrid taste which it possesses, it is probably of equal value to the other kinds.

S. officinalis.—In this species the stem is twining, angular, smooth, and prickly; the young shoots are unarmed; the leaves ovate-oblong, acute, cordiform, five- or seven-nerved, coriaceous, smooth, twelve inches long and four or five broad, with footstalks an inch long, smooth, and furnished with tendrils. The young leaves are lanceolate-oblong, acuminate, and three-nerved. Large quantities of the root are said to be sent down the Magdalena River to Mompox and Carthagena.

It is the source of *Honduras Sarsaparilla.* It is brought from the bay of Honduras and comes in bundles two or three feet long, composed of several roots folded lengthwise, and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing one hundred pounds or more. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached. In some bundles are many small fibers, either lying loose or still adhering to the roots. The roots externally are a dirty grayish or reddish-brown; the cortical portion beneath the epidermis often appears amylaceous when broken.

S. ornata Hook.—This plant was recognized by both Flückiger and Hanbury, and by Bentley and Trimen as *S. officinalis,* and was described by Lemaire with a query to it to express his doubtfulness of its specific distinctness. The species is, however, now generally accepted. The plant has large seven-nerved leaves resembling *S. officinalis.* It is especially distinguished by the young leaves being mottled with white. (See *Botanical Magazine,* 1889, cxv, 7054.)

This species yields *Jamaica* or *red sarsaparilla* of foreign writers, although but little known by the latter name in the United States. It is collected in Central America, especially in Costa Rica, and it owes its name to the fact that it has been largely exported to Europe through the island of Jamaica. As found in commerce it is in rolls from twelve to eighteen inches long by four or five in thickness, composed exclusively of long slender many-radicled roots very loosely held together by a few turns. Sometimes it is pressed into large bales. It is further to be distinguished from Honduras sarsaparilla by its dark color, the greater abundance of coarse rootlets, the less quantity of starch, its relatively thick cortex, and its less sharp taste. Externally it is also redder than is commonly the case with Honduras sarsaparilla. Kobert (*P. J.,* 1912, lxxxviii, p. 779), has found that the *ornata* has only one-eighth of the hemolytic power of the Vera Cruz sarsaparilla, which he takes as a test of its saponin content. He believes the plant is unfit for medical use.

Cultivated Jamaica Sarsaparilla (*Roja Inglesa*) occurs in thick short rolls and is especially characterized by its yellow-brown or orange color. According to W. B. Hemsley, Hooker's I. P. pl. 2589, it is the product of *S. utilis* Hemsley, a species related to *S. ornata,* from which it differs by its long pediculated simple umbels.

An investigation by Power and Salway (*Chem. News,* 1914, p. 56) showed the presence of the following constituents in *Jamaica sarsaparilla:* a glucoside, *sarsaponin,* $C_{44}H_{76}O_{20}7H_2O$, which upon hydrolysis yields *sarsapogenin,* $C_{26}H_{42}O_3$, and dextrose; *sitosterol-d-glucoside,* $C_{33}H_{56}O_6$; *sitosterol,* $C_{27}H_{46}O$; *stigmasterol,* $C_{30}H_{50}O$; *sarsapic acid* (a new dicarboxylic acid), $C_6H_4O_6$, and a mixture of fatty acids, including palmitic, stearic, behenic, oleic and linolic acids. The alcoholic extract contained *acetyl-d-glucoside* and potassium nitrate was also found.

Another variety is the *Carácas sarsaparilla,* brought in large quantities from La Guayra. It is in oblong packages, of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, leaving much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and carefully. The radicles are often very amylaceous internally, in this respect resembling the following variety.

S. papyracea is said to have foliage like *S. officinalis,* with a multiangular stem, with squamiform thorns on the angles, and petioles which are vaginate for one-fourth their length. It is thought to be the source of Para sarsaparilla which is no longer found in commerce.

The *Brazilian,* or, as it is called in Europe, the *Lisbon* or *Pará sarsaparilla,* is not very plentiful in commerce. It comes from the ports of Pará and Maranham, in cylindrical bundles from three to five feet in length by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizome) and stems, and having a few radical fibers. It was also shown in the Brazilian exhibit in the Centennial Exhibition, neatly cut and tied into bundles about a foot long and eight inches in diameter. It is the variety of which Hancock speaks as celebrated throughout South America by the name of *Sarsa of the Rio Negro,* and was considered one of the most valuable varieties of the drug. It is distinguished by the thinness of its cortex, the large amount of starch that it contains and its large, radially elongated endodermal cells. It was said by Martius to be derived from *Smilax syphilitica;* but Hancock considers that portion of it which comes from the Rio Negro, and is shipped at Pará, as the product of an undescribed species, certainly not *S. syphilitica.* As determined by Richard, it is the product of the *S. papyracea* of Poiret.

The variety described by Bentley under the name of *Guatemala sarsaparilla* was collected in the province of Sacatapeques, about ninety miles from the sea. It is in cylindrical bundles about two feet eight inches long by four inches in diameter, composed of separate roots, arranged in parallel order, without rootstalk, and bound together by a few turns of the flexible stem of a monocotyledonous plant. The bundles resemble the Brazilian in arrangement, but are much less compact. It is amylaceous, has considerable acridity, and is probably one of the most efficient varieties. Bentley ascribes it to *S. papyracea.* For a particular description of the root, see *P. J.,* xii, 472.

Guayaquil sarsaparilla, according to Spruce, grows in valleys on the western slopes of the equatorial Andes. It is usually not in bundles, but carelessly packed in bales. "The rhizome and a portion of the stem are often present, the latter being round and prickly. The root is dark, large, and coarse-looking, with a good deal of fiber. The bark is furrowed, rather thick, and not mealy in the slenderer portions of the root, which is near the rootstalk; but, as the root becomes stout, so its bark becomes smoother, thicker, and amylaceous, exhibiting when cut a fawn-colored or pale yellow interior."

The root (rhizome) of *Smilax China,* a native of China and Japan, has been employed under the name of *China Root* for similar purposes with the official sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown color externally, whitish or of a light flesh-color internally, without odor, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid, like that of sarsaparilla. The root of *Smilax aspera* is said to be employed in the south of Europe as a substitute for sarsaparilla; but it has little reputation. The East India sarsaparilla, which was at one time referred to this species of smilax, is the product of *Hemidesmus indicus.* (See *Hemidesmus.*)

Under the name of *Raiz de china de México,* the Mexican Pharmacopœia recognizes the root of *S. rotundifolia* as diaphoretic and depurative, but, according to Maisch, this reference is incorrect. (See *A. J. P.,* 1879.)

Properties.—The several varieties of sarsaparilla are officially described as follows:

"Mexican Sarsaparilla.—In loose bundles, or pressed into bales, single bundles attaining a length of 60 cm. and composed of from 20 to 35 folded roots attached to a crown with one or more stout stems; roots from 3.5 to 6 mm. in diameter; externally grayish-brown to dark brown, minutely hairy, longitudinally furrowed, the furrows containing more or less of a blackish earth; fracture tough, fibrous; internally light brown with a more or less shrunken, mealy or sometimes horny cortex surrounding the porous central cylinder, pith distinct; nearly inodorous; taste mucilaginous, somewhat sweetish and acrid. Remove the woody, knotty crown with portions of the overground stems.

"Honduras Sarsaparilla.—In more or less compact, cylindrical bundles, attaining a length of 55 cm. and a diameter from 8 to 15 cm., consisting of the long, folded roots bound together by roots of the same plant; roots from 2 to 6 mm. in diameter; externally dark- or reddish-brown, longitudinally furrowed, the furrows usually free from soil; fracture fibrous; internally consisting of a grayish-white or dark brown cortex, a light yellow and porous central cylinder and a whitish pith; taste mucilaginous and slightly acrid.

"Jamaica Sarsaparilla.—In more or less compact and somewhat flattened bundles, from 30 to 45 cm. in length and from 10 to 15 cm. in width, consisting of the folded roots loosely bound with roots of the same plant; roots from 2 to 5 mm. in diameter; externally grayish-brown to reddish-brown, longitudinally wrinkled, more or less furrowed and bearing numerous coarse fibrous rootlets; taste somewhat sweet and slightly bitter.

"Under the microscope, transverse sections of all of the commercial varieties of Sarsaparilla show an epidermal layer with basal portions of root hairs; a hypodermis composed of several layers of strongly lignified cells, the walls being uniformly thickened, except in Mexican Sarsaparilla in which the inner walls are only slightly thickened; a cortex composed of numerous parenchyma cells mostly containing starch, some containing resin or raphides of calcium oxalate; an endodermis of a single layer of strongly lignifed cells, the walls being uni-

formly thickened except in Mexican Sarsaparilla in which the outer walls are only slightly thickened; a central cylinder composed of radial bundles connected with sclerenchymatous fibers, the tracheæ being large and oval and the phloem in small groups at the periphery of the bundle; and a pith composed of starch-bearing parenchyma cells. Powdered Sarsaparilla is light grayish-brown to dark grayish-brown; when examined under the microscope it exhibits numerous starch grains, from 0.003 to 0.023 mm. in diameter, spherical, or biconvex or spherical-tetrahedral, single to 2- to 4-compound, and frequently with a central-elliptical cleft; calcium oxalate in raphides, from 0.006 to 0.035 mm. in diameter, occurring singly or in groups; cells of the hypodermis and endodermis with lemon-yellow or reddish-yellow porous walls and, in the case of Mexican Sarsaparilla, showing an uneven or irregular thickening, the individual cells from 0.08 to 0.5 mm. in length; fragments of tracheæ with simple and bordered pores or scalariform or reticulate thickenings associated with sclerenchymatous fibers having rather thin, very slightly lignified and porous walls. Sarsaparilla yields not more than 10 per cent. of ash." *U. S.*

According to Tunmann (*Apoth. Zeit.*, xxv, p. 475), the consumption of sarsaparilla in Europe has decreased materially, and the chief market for this drug at the present time appears to be the United States. While the U. S. Pharmacopœia recognizes three commercial varieties, most of the drug which is used is the Mexican variety, a relatively small quantity of Honduras sarsaparilla being imported. The *red Jamaica, Orange* or *Native Jamaica* varieties are used chiefly in England. Hartwich has recently pointed out that the varieties of sarsaparilla on the market are more numerous than are generally supposed. He also states that the greatest emphasis should be placed on the structural characteristics in order to distinguish the several varieties, rather than the form of packing and the supposed botanical origin. He is the best authority on this subject and all of his articles, some of which are enumerated, should be consulted (*S. W. P.*, 1897, No. 44 and 45; 1898, No. 37, and 1909, p. 126; *Arch. d. Pharm.*, 1894, p. 37, and 1902, p. 325; *Ber. d. D. Pharm. Ges.*, 1907, p. 250). A recent article on the pharmacognosy of the several commercial sarsaparillas is by Fleury in *Bull. des Sc. Pharmacol.*, xii, p. 190. Rusby reports finding lots of Mexican sarsaparilla which consisted entirely of "butts" or rhizomes. (*Proc. A. Ph. A.*, 1908, lvi, p. 773.) Kraemer reports finding nineteen ounces of dirt in a bundle of Mexican sarsaparilla weighing four and a half pounds. (*Proc. A. Ph. A.*, 1906, liv, p. 345.) Rusby has reported the presence of a thick, blackish, woody and decidedly astringent root in several shipments of Vera Cruz sarsaparilla. (*Jour. A. Ph. A.*, 1913, p. 1104.)

Sarsaparilla is efficient in proportion as it is acrid to the taste, which is said by some authors to be confined to the cortical portion, while the ligneous fiber and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes, and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water, cold or hot, but are impaired by long boiling. They are extracted also by diluted alcohol. According to Hancock, the whole of the active matter is not extracted by water. In South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous fermentation and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists. It has been suggested that sarsaparilla, the virtues of which are admitted to be impaired by long boiling, might also be injured by the degree of heat applied in the water or steam bath. But the contrary appears to have been proved by J. F. Judge of Cincinnati. (*Proc. A. Ph. A.*, 1873, p. 595.)

Parillin. (*Smilacin. Pariglin. Salseparin. Parallinic acid.*)—The crystalline principle to which any activity of sarsaparilla is due is now called *parillin*. It was first discovered by Palotta, who described it in 1824 under the name of *pariglin*. Subsequently, Folchi supposed that he had found another principle, which he called *smilacin*. Flückiger recommends the preparation of *parillin* by exhausting the crushed root with warm alcohol and distilling the tincture until the residue weighs one-sixth of the root. It is then gradually mixed with one and a half times its weight of water, and after several days the liquid is decanted from the light yellow precipitate, which is then mixed with about half its volume of alcohol, transferred to a filter, and washed with alcohol of 20 or 30 per cent. because parillin is less soluble in weak alcohol than in strong alcohol. The yield was 0.18 and 0.19 per cent. It is white, inodorous, almost tasteless in the solid state, but bitter, acrid, and nauseous when dissolved in alcohol or water. It is very slightly soluble in cold water, but more readily in boiling water, without crystallizing on cooling. It is very soluble in alcohol, especially at the boiling temperature. Ether and the volatile oils also dissolve it. Its aqueous solution has the property of frothing very much on agitation. According to Flückiger, concentrated sulphuric acid yields a yellow solution, which, on absorbing moisture, gradually turns cherry-red; warm diluted sulphuric acid colors parillin greenish, then red, and finally brown; phosphoric acid has a similar reaction, but the color is more greenish-yellow. The aqueous solution is precipitated by alcoholic solution of lead acetate, by lead subacetate, and by tannin, and when warmed reduces alkaline copper tartrate, but does not react with other tests for sugar until

after it has been boiled with a dilute acid, when the solution acquires a green fluorescence. This is best observed if a trace of parillin is dissolved in warm concentrated sulphuric acid, and disappears on dilution with water or on neutralizing with ammonia. Parillin is not sternutatory; its acrid taste is best observed in alcoholic solution. (See *A. J. P.*, xii, 245.) The solutions of parillin are without acid or alkaline reaction. By treatment with dilute mineral acids, it is resolved into *parigenin* and sugar. Poggiale found parillin both in the cortical and in the medullary part of the root, but most largely in the former. W. von Schulz (*P. J.*, 1892, 6) has shown that Dragendorff's *smilacin, smila-saponin,* or *sarsaparill-saponin,* $C_{20}H_{32}O_{10}$, *sarsa-saponin,* $C_{22}H_{36}O_{10}$, discovered by himself, and Flückiger's *parillin,* $C_{26}H_{44}O_{10}$; are three homologous compounds all belonging to the same series, having the general formula $C_nH_{2n-8}O_{10}$. These three all split up into *sarsasapogenin* (parigenin of Flückiger) and one or more molecules of glucose on boiling with dilute acids. Kobert (*A. J. P.*, 1892, 465) comes to practically the same results, stating the constituents to be *parillin* ($C_{26}H_{44}O_{10} + 2\frac{1}{2}H_2O$), insoluble in water; *saponin* (sarsaparill-saponin), $5(C_{20}H_{32}O_{10} + 2\frac{1}{2}H_2O)$, soluble in water; and *sarsa-saponin,* $12(C_{22}H_{36}O_{10} + 2H_2O)$, easily soluble in water, and the most active of the constituents.

The sarsaparilla of commerce is apt to be nearly if not quite inert, either from age, or from having been obtained from inferior species of Smilax. This inequality of the medicine, with the improper modes of preparing it long in vogue, has probably contributed to its variable reputation. The only criterion of good sarsaparilla to be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert. Various false sarsaparillas have been sent into commerce from South America. For description by C. Hartwich see *A. Pharm.*, July, 1902.

Uses.—The use of sarsaparilla in medicine is an interesting example of the power of superstition to survive the attacks of truth and reason. It was introduced into Europe about the middle of the 16th century as a remedy for *syphilis,* but soon fell into disrepute until revived by Fordyce in 1757. Subsequently it came to be used as an alterative in various other chronic diseases, especially *chronic rheumatism* and *scrofula.* There is, however, no reason to believe that it possesses any virtues except as a mild gastric irritant through its saponin content. Its most popular employment is in the form of its compound syrup which is used as a vehicle especially for mercury and potassium iodide.

Sarsaparilla may be administered in the form of infusion, compound decoction, compound syrup, or fluidextract. A beer made by fermenting an infusion of the drug with molasses is said to be a popular remedy in South America. The smoke of sarsaparilla has been highly recommended in *asthma.* (*J. P. C.*, xviii, 221.)

Dose, thirty to sixty grains (2–3.9 Gm.).

SASSAFRAS. U. S.

SASSAFRAS Sassaf.

(săs'sa-frăs)

"The bark of the root of *Sassafras variifolium* (Salisbury) O. Kuntze (Fam. *Lauraceæ*), without the presence or admixture of more than 2 per cent. of adhering wood, collected in the early spring or autumn, deprived of the outer corky layer and dried." *U. S.*

Sassafras Radix, *Br.*; Sassafras Bark, Sassafrax; Sassafras, *Fr. Cod., G.*; Sassafrasso, *It.*; Sasafras (Leño de), *Sp.*

Sassafras is an indigenous tree, of medium size, rising in favorable situations to a height of 35 feet. The bark of the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side, but the greater number are three-lobed. The flowers, which appear before the leaves, are small, of a pale greenish-yellow color, and disposed in racemes which arise from the branches below the leaves and have linear bracts at their base. The fruit is an oval drupe, about as large as a pea, of a deep blue color when ripe, and supported on a red pedicel, enlarged at the extremity into a cup for its reception. For the microscopical character of the root and bark, see E. S. Bastin, *A. J. P.*, June, 1895. See also *Ph. Rev.*, 1899, 450.

The sassafras is common throughout the eastern United States, and extends into Mexico. The fresh flowers have a slightly fragrant odor, and almost all parts of the plant are more or less aromatic. The best time for collecting the pith is after the occurrence of frost in autumn, and the same is the case also with the bark of the root.

Bark of Sassafras Root.—As found in commerce, this is usually in small irregular fragments, sometimes invested with a brownish cork, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter color than that of the exposed surfaces. The living bark is nearly white, but becomes colored, on exposure, immediately after collection. It is officially described as "in irregularly transversely curved or quilled pieces, from 1 to 15 cm. in length and from 1 to 4 mm. in thickness; outer surface orange-brown, nearly smooth and marked with more or less irregular ridges; inner surface light to dark reddish-

brown, obscurely short-striate; fracture short with a thin reddish-brown corky layer and a yellowish-white inner bark; odor aromatic; taste slightly mucilaginous, astringent, aromatic and somewhat pungent. The powder is light reddish-brown; when examined under the microscope it exhibits numerous starch grains and prominent, characteristic bast-fibers; starch grains either single or 2- to 4-compound, the individual grains being more or less spherical or polygonal and frequently with a distinct cleft, from 0.003 to 0.02 mm. in diameter, some of the swollen or altered grains attaining a diameter of 0.03 mm.; bast-fibers spindle-shaped, occasionally very irregular in outline, with sharply pointed ends, from 0.15 to 0.4 mm. in length, about 0.025 mm. in diameter, and with very thick, strongly lignified walls, the lumina being frequently nearly obliterated; parenchyma cells containing either starch grains or irregular yellowish-red masses of tannin and becoming bluish-black upon the addition of ferric chloride T.S.; fragments of wood few, with large, thin-walled tracheæ marked by simple pores and associated with rather thin-walled wood-fibers. Sassafras yields not more than 30 per cent. of ash." *U. S.*

According to Reinsch, the bark contains a heavy and light volatile oil, camphorous matter, fatty matter, resin, wax, a peculiar decomposition product of tannic acid called *sassafrid*, tannic acid, gum, albumen, starch, lignin, and salts. (See *Oleum Sassafras*, page 790.) The sassafrid bears some analogy to cinchonic red, and, like it, appears to be a derivative of the tannin, which exists in much larger proportion in the fresh bark than in that long kept. (Procter, *A. J. P.*, 1866, p. 490.) Owing to its volatile oil and tannic acid, the bark of sassafras root is an aromatic stimulant and astringent. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavor of which it improves, while it renders them more acceptable to the stomach. The volatile oil may be used as an aromatic. In overdoses it is capable of producing marked narcotic poisoning, and it is said to act upon the lower animals as a narcotic. John Bartlett has reported several cases in which its use apparently caused abortion.

Sassafras Pith (*Sassafras medulla*) was recognized by the U. S. VIII, and is at present included in the N. F. IV. It occurs in "subcylindrical, often curved or coiled pieces, from 2 to 10 cm. in length and from 2 to 5 mm. in diameter; very light in weight; externally whitish, occasionally with small fragments of adhering wood; fracture short. Odor slight; sassafras-like; taste mucilaginous. When examined under the microscope, transverse sections of Sassafras Pith, mounted in phloroglucinol T.S. and hydrochloric acid, show nearly isodiametric cells with large intercellular spaces, the walls being more or less lignified and provided with numerous simple pores; mounts made in water show the separation of a thin layer of mucilage from the inner walls of the cells, characterized by the gradual disappearance of the pores. Macerate 0.5 Gm. of Sassafras Pith with 25 mils of cold distilled water for several hours and filter it through purified cotton; a mucilaginous solution is obtained which does not give a precipitate upon the addition of an equal volume of alcohol." *N. F.*

It abounds in a gummy matter, which it readily imparts to water, forming a limpid mucilage, which is not precipitated by alcohol, but has much less tenacity than that of gum arabic and will not answer as a substitute in the suspension of insoluble substances. This mucilage is much employed as a soothing application in inflammation of the eyes, and forms an agreeable and useful drink in *dysenteric, catarrhal,* and *nephritic* diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

Dose, of sassafras bark, one to two drachms (3.9–7.7 Gm.).

SCAMMONIÆ RADIX. U. S., Br.

SCAMMONY ROOT Scam. Rad.

(scăm-mō'nī-æ rā'dĭx)

"The dried root of *Convolvulus Scammonia* Linné (Fam. *Convolvulaceæ*), yielding not less than 8 per cent. of the total resins of Scammony Root." *U. S.* "Scammony Root is the dried root of Convolvulus Scammonia, *Linn.*" *Br.*

As the resin of scammony is obtained in Oriental countries by a somewhat tedious process, it has been very difficult to obtain sufficient quantities of the genuine article for use in medicine. The British Pharmacopœia long ago solved the question by making official *scammony root* from which the resin is prepared. The U. S. P. IX following this precedent and for the same reason has introduced scammony root. There seems to be little doubt, however, that the natural exudation has properties which make it a more desirable medicine than the extracted resin. (*C. D.*, lxix, p. 864.) On the other hand, the therapeutic committee of the British Medical Association states that the natural exudation possesses no advantages over the resin. (*P. J.*, 1908, xxvii, p. 811.) Heuisler states that the extracted resin of true scammony root as well as the resin obtained from Mexican scammony (*Ipomœa Orizabensis*) are sold for "virgin" scammony. (*Proc. Md. Ph. Assoc.*, 1908, p. 35.)

Scammony root is officially described as follows: "Cylindrical or somewhat tapering, from 10 to 25 cm. in length and from 1 to 4.5 cm. in thickness; externally grayish- to reddish-brown; usually distinctly twisted, deeply longitudinally furrowed, marked by distinct root-scars, otherwise nearly smooth except for the lenticels and abraded cork, the upper portion terminated usually by a number of short stem branches; hard and heavy; fracture tough, irregular with projecting wood-fibers; internally somewhat mottled, showing yellowish, porous wood-wedges separated by whitish parenchyma containing starch and resin, bark thin; odor slight, re-

sembling that of jalap; taste very slightly sweet, becoming slightly acrid. Under the microscope, sections of Scammony Root show a corky layer consisting of from 2 to 10 rows of cells with thin, yellowish-brown lignified walls; an outer cortex with numerous stone cells occurring singly or in small groups, the walls being moderately thick, porous and not strongly lignified; parenchyma with numerous starch grains and monoclinic prisms of calcium oxalate; fibro-vascular bundles numerous, circular or elliptical with a well developed wood consisting of large tracheæ surrounded by slightly lignified wood-fibers; phloem or sieve prominent in which are included large resin ducts; the parenchyma, both in and surrounding the bundles, more or less collapsed and containing either starch or calcium oxalate crystals. The powder is light grayish-brown; when examined under the microscope it exhibits starch grains from 0.003 to 0.018 mm. in diameter, mostly single, occasionally 2- to 4-compound, the grains showing occasionally a central cleft; calcium oxalate crystals numerous, in monoclinic prisms from 0.01 to 0.045 mm. in length; fragments of leptomes or sieve with accompanying yellowish-brown resin cells; tracheæ mostly with reticulate thickenings and simple or bordered pores and associated with short wood-fibers having prominent oblique pores; stone cells of variable shape and varying from 0.04 to 0.11 mm. in length, the walls being from 0.006 to 0.012 mm. in thickness, slightly lignified and traversed with prominent, often branching pores; lignified cork cells relatively few.

"**Assay.**—Proceed as directed under *Jalapa*, using 10 Gm. of Scammony Root in No. 60 powder." *U. S.*

"Brownish-grey or yellowish-grey, tapering or nearly cylindrical, varying usually from two to eight centimetres, or more, in diameter. Frequently contorted and longitudinally furrowed; enlarged at the crown, and bearing the remains of slender aerial stems. Fracture very coarsely fibrous; internally light or dark grey. In transverse section, numerous rounded wood-bundles distributed throughout a paler ground-tissue in which dark resin cells can be distinguished with a lens; in the parenchymatous tissue abundant, characteristic starch grains. Characteristic odor; taste at first somewhat sweet, afterwards slightly acrid. Yields to *alcohol* (90 per cent.) a resin which has the properties described under 'Scammoniæ Resina.'" *Br.*

The wood consists of compressed pale brown, coarsely porous, usually subdivided fibers in a parenchymatous tissue similar to the bark. For microscopic structure, see *Dragendorff's Jahresbericht*, 1875.

The root of the *male jalap* (*orizaba root, Mexican scammony, Purgo macho*) has recently largely replaced in commerce the scammony root on account of its containing a much larger percentage of resin chemically indistinguishable from that of scammony. The Levant or true scammony root, it is said, averages a little under 9 per cent. of resin, while the Mexican root usually yields over 15 per cent. Male jalap occurs in transverse pieces one-half to an inch in thickness and two to four inches in diameter or in the case of the smaller roots in pieces three or four inches long sometimes obliquely cut, the transverse slices show concentric rings with protruding coarse fibers which at once distinguishes it from the true scammony in which the vascular bundles are scattered.

Large quantities of a false scammony root of unknown botanical origin have appeared in the London market. The root is 2 to 3 inches in diameter with a thin, brittle, blackish-brown bark, and on transverse section six or seven rings of wood. It is odorless and tasteless. (See *P. J.*, May, 1901, 596.)

Mexican Scammony Root.—Mexican scammony root has been identified by E. M. Holmes as being undoubtedly the root of *Ipomœa orizabensis*, and is described as follows: The appearance is quite characteristic and quite different from that of scammony root. It occurs mostly in transverse slices, showing concentric rings, from which coarse fibers protrude on both of the transverse surfaces. The sections are mostly those of the larger portion of the root, and vary from two to three inches or more in diameter, but are only about one-half to three-quarter inch in thickness. The smaller roots are about one inch or so in diameter, but are frequently three or four inches long; a few pieces are obliquely cut. The concentric arrangement of the vascular bundles at once distinguishes it from the root of *Convolvulus Scammonia*, in which they are scattered and somewhat rounded, forming isolated strands, in the softer tissue. It appears that during 1903 there was an importation of over 3000 bags, which sold readily to the German makers of scammony resin. Analyses made showed from 6.4 to 22.2 per cent. of resin, but most of it yielded about 17 per cent. While chemically there appears to be no difference between scammony resin and the resin of *Ipomœa orizabensis*, it remains to be ascertained if they are identical in their physiological action. At the request of Holmes, Harold Dean determined the amount of resin in a specimen and, in a separate paper, gives the method employed and the results, as follows: The drug was powdered, exhausted by percolation with alcohol (90 per cent.), the greater part of the alcohol distilled off, and the resulting strong tincture poured into three times its volume of water. The resin separated as a mass of honey-like consistence. It was well washed with boiling water until the washings were free from sugar and from color, and then dried on a water bath until the weight was constant. The yield of resin amounted to 18.5 Gm. from 100 Gm. of the powdered drug; this is the highest percentage yet recorded from this source. The dried resin was pale brown, and almost entirely soluble in ether, the insoluble portion from 18.5 Gm. weighing less than 0.25 Gm. It had the general characteristics of scammony resin. The powdered drug, dried at

100° C. (212° F.), yielded 9.89 per cent. of ash. (*P. J.*, March 5, 1904, 226, 327.)

Uses.—Scammony root in substance is not used medicinally, but solely for making resin of scammony.

SCILLA. U. S., Br.

SQUILL Scill.

(sçĭl'lą)

"The fleshy, inner scales of the bulb of the white variety of *Urginea maritima* (Linné) Baker (Fam. *Liliaceæ*), cut into pieces and carefully dried. Preserve Squill in tightly-closed containers, in a dry place. If made into the official tincture and assayed biologically, the minimum lethal dose should not be greater than 0.006 mil of tincture, or the equivalent in tincture of 0.0000005 Gm. of ouabain, for each gramme of body-weight of frog." *U. S.*

"Squill is the bulb of Urginea Scilla, *Steinh.*, divested of its dry membranous outer scales, cut into slices, and dried. When powdered should be kept quite dry over quicklime." *Br.*

Squills; Scille, *Fr. Cod.*; Bulbus Scillæ, *P. G.*; Meerzwiebel, *G.*; Scilla, *It.*; Escila (Bulbo de), Cebolla albarrana, *Sp.*

Urginea maritima (*Urginea Scilla* Steinh.) is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish peduncles, at the base of each of which is a linear, twisted, deciduous floral leaf. The squill grows on the sea coast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the official portion. It is generally dried for use, but is sometimes imported in the recent state packed in sand.

Properties.—The fresh bulb is pear-shaped, from 15 to 30 cm. in diameter, weighing as much as 5 or 6 pounds, and consists of fleshy scales attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two varieties, distinguished as the *red* and the *white squill*. In the former the exterior coating is of a deep reddish-brown color, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter the whole bulb is white. They do not differ in medicinal virtue. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the mucilaginous character of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of activity, the latter too fleshy and mucilaginous.

Dried squill, as found in commerce, is "in irregular, more or less curved, somewhat flattened pieces, from 0.5 to 5 cm. in length, yellowish-white, somewhat translucent, nearly smooth and lustrous with slight projections of fibro-vascular bundles; brittle when dry and somewhat flexible when damp; odor slight; taste bitter and acrid. Under the microscope, sections of the scales of Squill show on the upper and lower surface a thin-walled epidermal layer, a mesophyll of nearly isodiametric or slightly elongated thin-walled cells and occasionally show in alcoholic or glycerin mounts spheroidal aggregates of a carbohydrate; numerous more or less rectangular cells containing mucilage and bundles of raphides of calcium oxalate, the latter from 0.075 to 1.0 mm. in length; fibro-vascular bundles few and isolated, with spiral or reticulate tracheæ. Occasionally some of the parenchyma cells contain a few somewhat spherical starch grains. The powder is light yellow, with a tendency to cake in moist atmosphere and consisting of very irregular fragments; when examined under the microscope it exhibits numerous single crystals and bundles of long raphides of calcium oxalate; fragments of thin-walled, colorless parenchyma, frequently with dark intercellular spaces due to the inclusion of air; fragments with spiral or reticulate tracheæ are occasionally found. Squill yields not more than 8 per cent. of ash.

Examined by the microscope, the bulb is seen to be pervaded by innumerable minute acicular crystals of calcium oxalate. According to Hartwich, the mucilage occurs either in the form of large drops, filling the parenchymatous cells, or as masses enclosing the raphides. For an elaborate microscopic study, with plates, see *A. Pharm.*, July, 1889. Water distilled from it had neither taste nor odor, and was drunk by Vogel to the amount of six ounces without effect. When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture it soon becomes mouldy.

"**Assay.**—For a method for assaying Squill see Biological Assays (Part III)." *U. S.*

"In curved, yellowish-white, somewhat translucent strips, from about two and a half to five centimetres long, frequently tapering towards both ends; tough and slightly flexible while moist, but brittle and easily pulverisable when dry. Almost inodorous; taste disagreeably bitter. Ash not more than 5 per cent." *Br.*

The virtues of squill are extracted by alcohol, but apparently only in part by water. It has been analyzed by Vogel, J. H. Marais, Lebourdais, Tilloy, Merck, and by Schmiedeberg (*Zeit. Physiol. Chem.*, 111, 112) with varying results. The bitter principle, not yet obtained pure, is *scillitin*. Merck, however, obtained three compounds of this class—*scillipicrin*, *scillitoxin*, and *scillin*. Jarmersted (*A. E. P. P.*, 11, 22) obtained a glucoside which he called *scillain*, but which seems to be identical with scillitoxin.

Ewins (*J. P. and Ex. T.*, 1912, ii, p. 155) separated from the squill two active principles, although neither of them in crystallizable form. The first is water soluble glucoside, which is fatal to the frog in doses of 0.03 Gm. for a 25 gramme frog. The second is a resinous body, very slightly soluble in water, but readily so in alcohol. Fatal dose for a frog is 0.06. Besides these they found a trace of caffeine. These authors state and it is generally acknowledged that the so-called active principles of squill which are found upon the market are not true principles but are impure bodies.

Schmiedeberg found a peculiar mucilage, analogous to dextrin, which he calls *sinistrin*, $(C_6H_{10}O_5)_n$. It is white, easily soluble in water, insoluble in alcohol, lævo-rotatory; on boiling with dilute sulphuric acid it yields levulose and an inactive sugar of reducing properties. The mucilage is not affected by saliva or diastase. This last statement, however, was contradicted by F. Kurtz (*A. J. P.*, 1894, 246), who says that diastase acts upon it, producing a reducing sugar. Kurtz also obtained a reducing sugar (probably dextrose) along with the gum direct by extracting the bulb with hot alcohol. S. Wanizewski (*A. J. P.*, 1893, 498) found *scillinine*, soluble in alcohol, but insoluble in water and in chloroform; *scillapicrine*, soluble in both water and alcohol, and *scillamarine*, soluble in both chloroform and alcohol. The bulbs of *Scilla maritima* also yield a slightly colored liquid oil of unpleasant odor when distilled in a current of steam. (*Husemann's Pflanzenstoffe*, 2d ed., p. 406.)

Uses.—Squill belongs to that series of drugs, commonly known as the digitalis group, which have for their characteristic properties the power of slowing and strengthening the pulse, of contracting the blood vessels, and in toxic doses causing systolic spasm of the frog's heart. (See *Digitalis*, p. 408.) While it in many regards closely resembles digitalis in its physiological action, it is notable for the strong degree of vasomotor action and for its local irritant effect. Probably by virtue of its effects on the circulation, but also largely because of its local irritant action upon the renal epithelium, squill is one of the most active diuretics among this group of drugs. Indeed it is so stimulating to the kidney that in overdose it is capable of causing an acute inflammation of this organ. When given in large dose, partly because of the central emetic effect which is characteristic of the digitalis group, but largely because of its local irritant influence upon the stomach, it produces severe nausea and even vomiting. In overdoses it has been known to cause hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels.

While squill is capable of exercising all the beneficial effects of digitalis in chronic *heart disease*, because of its action upon the alimentary canal it is rarely employed for this condition unless associated with *dropsy*. Because of its stimulant action upon the kidney as well as upon the heart, it is peculiarly useful for the evacuation of edematous infusions due to weakness of the heart, and is also sometimes of service in the ascites of *hepatic cirrhosis*. When, however, there is active inflammation of the kidney it must be used with great caution if at all. Like other emetic drugs, if given in sufficient doses to nauseate it tends to increase in the bronchial secretions and is occasionally used as an expectorant in *bronchitis* and *spasmodic croup*. Because of its potent action upon the circulation its use for this purpose, however, is not to be encouraged.

Neither water nor dilute acetic acid entirely extract the activity of squill. The only liquid preparations, therefore, which thoroughly represent the drug are those made with alcohol, of which the tincture is probably the better.

When given in substance it is most conveniently administered in the form of pill.

Dose, of squill, from one to two grains (0.065–0.13 Gm.).

SCOPARII CACUMINA. Br.

BROOM TOPS

(scō-pā'rī-ī că-cū'mĭ-nă)

"Broom Tops are the fresh and the dried tops of Cytisus scoparius, *Link*." *Br.* "The dried top of *Cytisus Scoparius* (Linné) Link (Fam. *Leguminosæ*)." *N. F.*

Scoparius, *N. F.*; Herba Scoparii, Spartium; **Irish or Scotch Broom**, Besom, Genêt à balais, *Fr.*; Gemeine Besenginster, Besenginster, Besenkraut, Pfriemenkraut, *G.*

Cytisus scoparius is a common European shrub, cultivated as a sand-binder and locally naturalized on the Atlantic Coast from Nantucket to Virginia. It is a low, densely branched shrub, from three to eight feet high, with numerous straight, pentangular, bright green, very flexible branches, and small, oblong, glabrous leaves, usually ternate, but on the upper part of the plant sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow color, and solitary upon short

axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures. It is essential that true broom be carefully distinguished from *Spanish broom* (*Spartium Junceum*), since a number of cases of poisoning have occurred from the substitution of the dried flowers of Spartium for those of broom. (See Part II.)

The whole plant has a bitter, nauseous taste, and, when bruised, a strong, peculiar odor. The tops of the branches are used in medicine. They are in "thin, flexible, branched twigs, from 2 to 3 mm. in thickness, five-angled; externally dark green, nearly glabrous, with numerous reddish-brown cork patches; internally yellowish, fracture short-fibrous, that of thicker pieces tough and splintery, upper leaves sessile, with often only one obovate leaflet present in small amount or absent. Odor slight, on bruising more distinct and peculiar; taste disagreeable, bitter. Scoparius yields not more than 5 per cent. of ash." *N. F. IV.*

"Stem dark green, with long, straight, slender, alternate branches; the latter, like the upper part of the stem, winged, tough, flexible, and glabrous. Leaves, when present, small, sessile, and simple above, stalked and trifoliate below. Odor of the fresh tops, especially when bruised, characteristic; the dry tops almost inodorous." *Br.*

The seeds are reported to be used sometimes, and to be as active as the tops. Water and alcohol extract their active properties. According to Cadet de Gassicourt, the flowers contain volatile oil, fatty matter, wax, chlorophyll, yellow coloring matter, tannin, a sweet substance, mucilage, albumen, and lignin. Stenhouse has separated from them two principles, *scoparin,* $C_{21}H_{22}O_{10}$ (Goldschmidt and Himmelmayer (*Ap. Ztg.,* 1893, 566) give the following formula of scoparin: $C_{10}H_{16}O_8(OH)(OCH_3)$), and an alkaloid, *sparteine,* $C_{15}H_{26}N_2$. The former is in stellate crystals, easily dissolved by boiling water and alcohol, and is obtained by purifying a yellow gelatinous substance deposited upon the evaporation of the decoction. It is only slightly soluble in cold water, more readily in hot water with greenish light yellow color, easily soluble in aqueous ammonia and caustic and carbonated alkalies. It is decomposed by heat. When fused with potassium hydroxide it yields, according to Hlasiwetz, phloroglucin and protocatechuic acid. Sparteine was obtained by distillation from the mother waters of the scoparin. It is a colorless liquid, having a peculiar bitter taste, and all the properties of a volatile alkaloid. It is heavier than water, and boils at 288° C. (550.4° F.) if distilled in a current of hydrogen gas. It dissolves only slightly in water, but takes up some water itself. In contact with water it becomes opalescent. It turns yellowish on distillation in air, but can be distilled colorless in an atmosphere of carbon dioxide. It is colorless, but becomes brown by exposure to light; it has at first an odor of aniline, but this is altered by rectification. It readily neutralizes acids and forms crystallizable salts, which are extremely bitter. Its sulphate occurs in colorless crystals, and is freely soluble in water. (See *P. J.,* June 28, 1879; also *Sparteinæ Sulphas.*) By the action of potassium dichromate and sulphuric acid, *oxysparteine,* $C_{15}H_{24}N_2O$, is formed, and by the action of hydrogen dioxide upon this, a deliquescent *trioxysparteine,* $C_{15}H_{24}N_2O_3$, is obtained; if the hydrogen dioxide acts upon sparteine itself, *dioxysparteine,* $C_{15}H_{24}N_2O_2$, is formed as a solid, crystallizing in prisms melting at 128.5° C. (263.3° F.). Zinc and hydrochloric acid reduce sparteine to *hydrosparteine,* $C_{15}H_{28}N_2$, a thick liquid boiling at from 281° to 284° C. (537.8°–543.2° F.). (Schmidt, *Pharmaceutische Chemie,* 3te Auf., Bd. ii, 1276.)

Uses.—Scoparius is diuretic and cathartic, and in large doses emetic, and has been employed with advantage in *dropsy.* Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce (30 mils) every hour until it operated by stool or urine. The seeds may be given in powder, in the dose of from ten to fifteen grains (0.65–1.0 Gm.). A fluidextract is official in the N. F. IV (see Part III).

Scoparin probably represents the diuretic and purgative influences of scoparius, although its physiological and therapeutic properties have not as yet been sufficiently investigated. For description of the effects of *sparteine,* see *Sparteinæ Sulphas.*

Oxysparteine, $C_{15}H_{24}N_2O$.—This is an alkaloidal oxidation product of sparteine, originally described by F. Ahrens (*Ber. d. Chem. Ges.,* 1891). It occurs in white, somewhat hygroscopic needles, melting at about 84° C. (183.2° F.), soluble in water, alcohol, ether, and chloroform. It has been found by Hurthle(*A. E. P. P.,* 1892) to be a cardiac stimulant, decreasing the pulse rate, but markedly increasing the arterial pressure and heart work. The hydrochloride, which occurs in large needles (often consolidated together) and is very soluble in water, has been used hypodermically by von Oefele in cases of *heart failure.* The dose is half a grain (0.032 Gm.), rapidly increased to one and a half grains (0.096 Gm.). The system is said soon to become accustomed to it.

Dose, of scoparius, ten to fifteen grains (0.65–1.0 Gm.).

SCOPOLAMINÆ HYDROBROMIDUM. U. S. (Br.)

SCOPOLAMINE HYDROBROMIDE Scopolamin. Hydrobrom. [Scopolamine Bromide]

(skō-pō-lą-mĭ'næ hȳ-drō-brō'mĭ-dŭm)

"The hydrobromide [$C_{17}H_{21}O_4NHBr + 3H_2O = 438.15$] of lævorotatory scopolamine, also known as hyoscine, obtained from various plants of the *Solanaceæ.* Preserve it in well-closed

containers, protected from light." *U. S.* "Hyoscine Hydrobromide, $C_{17}H_{21}NO_4$, HBr,$3H_2O$, is the hydrobromide of an alkaloid, hyoscine or scopolamine, obtained from various plants of the natural order Solanaceæ." *Br.*

Hyoscinæ Hydrobromidum, *Br., U. S., VIII;* Hyoscine Hydrobromide; Bromhydrate d'Hyoscine, *Fr.;* Scopolaminum hydrobromicum, *P. G.;* Skopolaminhydrobromid, *G.;* Hyoscinum Hydrobromicum; Hydrobromate of Hyoscine, Scopolamine Hydrobromide; Bromhydrate d'Hyoscine, *Fr.;* Hyoscinhydrobromid, Bromwasserstoffsaures Hyoscin, *G.*

Scopolamine, $C_{17}H_{21}O_4N$, is found in the leaves and seeds of *Hyoscyamus niger, Duboisia myoporoides, Scopola japonica, Atropa Belladonna* and other solanaceous plants. When pure, it forms a syrupy liquid. The best salt for practical use is the hydrobromide, which is in "colorless, transparent, rhombic crystals, sometimes of large size; odorless; slightly efflorescent. *Great caution must be used in tasting it, and then only in dilute solutions.* One Gm. of Scopolamine Hydrobromide dissolves in 1.5 mils of water and in 20 mils of alcohol at 25° C. (77° F.); slightly soluble in chloroform; insoluble in ether. Its aqueous solution (1 in 20) is neutral or at most only slightly acid to litmus. When anhydrous it melts between 190° and 192° C. (374° and 377.6° F.). The specific rotatory power of the salt, determined in an aqueous solution containing the equivalent of 5 Gm. of anhydrous Scopolamine Hydrobromide in 100 mils of solution at 25° C. (77° F.), is from −22° to −25.75° in a 100 mm. tube (see Part III, Test No. 21). Add about 0.01 Gm. of the salt to 5 drops of nitric acid and evaporate it to dryness in a porcelain dish on a water bath; the residue yields a violet color upon the addition of alcoholic potassium hydroxide T.S. Silver nitrate T.S. produces in the aqueous solution of the salt a yellowish-white precipitate insoluble in nitric acid. Shake 2 mils of chloroform with 1 mil of an aqueous solution of the salt (1 in 20) to which a few drops of chlorine water have been added; the chloroform assumes a brownish color. When dried to constant weight at 100° C. (212° F.) it loses not more than 13 per cent. of its weight. It also loses its water of crystallization slowly over sulphuric acid. No weighable ash remains on incinerating 0.1 Gm. of Scopolamine Hydrobromide. The addition of a few drops of ammonia water T.S. to 1 mil of an aqueous solution of the salt (1 in 20) causes no turbidity; the addition of potassium hydroxide T.S. to another portion of 1 mil of the aqueous solution causes only a whitish, transient turbidity (*foreign alkaloids*). Add 0.05 mil of tenth-normal potassium permanganate V.S. to 15 mils of an aqueous solution of the salt (1 in 100); the solution is not completely decolorized within five minutes (*apoatropine*). The solution of about 0.1 Gm. of the salt in 1 mil of sulphuric acid is not more than faintly yellow (*carbonizable impurities*). Add a drop of nitric acid to this solution; an orange color is produced, due to the liberation of bromine, but no deep red color fading to orange is noticeable (*morphine*)." *U. S.*

"Small, colorless, transparent, non-deliquescent rhombic crystals. Soluble in 4 parts of *water.* Loses about 12 per cent. of its weight when dried at 100° C. (212° F.). Yields the *reactions* characteristic of bromides. An aqueous solution (5 in 100) yields with *solution of sodium hydroxide* a white precipitate soluble in excess of the reagent, but no precipitate with *solution of ammonia.* The alkaloid removed from the ammoniacal solution by shaking with *chloroform,* separating and evaporating the chloroformic solution, when dissolved in *diluted hydrochloric acid,* yields with *solution of auric chloride* a yellow precipitate, which, recrystallised from *water* acidified with *hydrochloric acid* and dried, melts at 198° to 200° C. (388.4°–392° F.). Treated with *nitric acid* as described under 'Atropina' a violet color is developed. No appreciable ash." *Br.*

E. Schmidt (*Ap. Ztg.,* 1891, 522) believes that the hyoscine hydrobromide of commerce is essentially hydrobromide of *scopolamine,* $C_{17}H_{21}NO_4$. This view has been confirmed by O. Hesse (*Ann. Ch. Ph.,* 1893, 304), and the British Pharmacopœia defines hyoscine as an alkaloid contained in different solanaceous plants, while the German Pharmacopœia changed the title to "Scopolaminum Hydrobromicum." The U. S. Pharmacopœia (8th Rev.) introduced Scopolaminæ Hydrobromidum as a separate title, but referred to Hyoscinæ Hydrobromidum for the description and tests, declaring them to be identical substances. *Atroscine,* an optically inert isomer of scopolamine, was found by Hesse in variable amount in the hyoscine hydrobromide of commerce. For further information on the chemistry of solanaceous alkaloids, see *Belladonnæ Radix,* p. 221.

Uses.—The older investigations into the effects of scopolamine upon the bodily functions are in many regards confusingly contradictory because of the failure to realize the difference in the physiological effects of *racemic* and *lævo-scopolamine.* While these two varieties of the alkaloid possess qualitatively the same physiological properties their actions are quantitatively so different that it is not to be wondered that different pharmacologists obtain such varying results. Lævo-scopolamine (the variety recognized by the U. S. P.) is paralyzant to the peripheral ends of the so-called autonomic nerves acting in this regard precisely like atropine, although less powerful. By virtue of this action it dilates the pupil, causes dryness of the throat and of the skin, accelerates the heart's action, etc. It differs strikingly from atropine however, in that it is not stimulant to the medullary centers and therefore does not increase the respiration nor elevate the blood pressure; and also in that it appears to act frequently as a cerebral depressant and tends to promote sleep. In some persons this sleep which it produces is interrupted or attended with a kind of low muttering delirium, recalling the mental confusion of atropine poisoning. A striking feature of the effects of large doses of scopolamine is the loss of memory for events which happened while under its influence. It has slight

analgesic properties, but according to the researches of Hauchold (*Z. E. P. T.*, 1910, vii, p. 743) greatly enhances the effect of other narcotics such as morphine or urethane. In large dose it is depressant to the respiratory center and apparently also in some degree to the motor ganglia of the spinal cord. The racemic scopolamine—sometimes known as atroscine—according to the studies of Cushny (*A. E. P. P.*, 1912, lxx, p. 433), differs from the optically active alkaloid only in being much less powerful in its effects upon the autonomic nerves. When locally applied it will cause dilatation of the pupil, but except in very large doses, it has no effect upon the pulse rate and scarcely any upon the secretions. Its action upon the central nervous system is about equal to that of the lævo-scopolamine.

The most important use of scopolamine is as a cerebral sedative. In ordinary *insomnias* it is usually much less efficient than the narcotics of the aliphatic group but is often useful as an adjuvant in the severer types of sleeplessness, such as seen in *delirium tremens*. In the *manias* it often acts most happily and in some cases even seems to exercise some curative influence. For the relief of *pain* it is rarely useful by itself, but may be advantageously combined with morphine. It is often of value as a symptomatic remedy in various forms of nervous excitement, such as is seen in *hysteria* or *neurasthenia*. It is probably its action upon the intellectual centers which make it so useful a drug in the treatment of *alcoholic* and other *drug habits*.

In a variety of other conditions of nervous excitement scopolamine has been found clinically useful, although its mode of action is not always clear, thus in *epilepsy*, while by itself of little avail, it greatly increases the effects of bromides; in *paralysis agitans* it is one of the most valuable drugs we possess; it is also useful to allay *sexual excitement* as *nymphomania* and *spermatorrhea*, and Hotz (*D. M. W.*, 1908) reports good results even in *tetanus*. As a mydriatic it is much quicker and less permanent in its effects than atropine and is therefore often used to paralyze accommodation in correcting errors of refraction.

In 1900 Schneiderlin, under the misapprehension that scopolamine was stimulating to the respiratory center, and would therefore antagonize depressant effects of morphine, introduced the use of a combination of these alkaloids as a means of producing surgical anesthesia. Under the catchy name of "*Twilight Sleep*" this method of anesthesia has been used to a large extent not only for surgical operations, but in obstetrics, either by itself or as a preliminary to the use of chloroform or ether. As the sole means of producing unconsciousness for surgical operations the *scopolamine-morphine anesthesia* is certainly not to be recommended as a routine measure. Not only is the anesthesia unsatisfactory in a very large proportion of cases, but the method has given an extraordinarily high mortality. In 1906, H. C. Wood, Jr. (*Amer. Med.*, xii, p. 544), collected statistics of two thousand cases showing a mortality of 1 in 221 anesthesias, and Avarffi subsequently (*J. A. M. A.*, 1910, liv) in six thousand anesthesias found a mortality of 1 in 150. In obstetrical practice while it is difficult to estimate the relative danger to the mother, the danger to the child seems to be distinctly greater than after either chloroform or ether. Avarffi found in the reports of a thousand cases over 17 per cent. of embarrassed respiration in the new-born infant. The question, however, of whether the use of scopolamine as a preliminary to ether anesthesia is advantageous or not is, as yet, a matter of great difference of opinion. While it is undoubted that the quantity of ether under such circumstances is less than that ordinarily required, it is not certain whether the danger is consequently diminished or not.

The ordinary dose of scopolamine ranges from 1/200 to 1/100 of a grain and occasionally even somewhat more. Many persons, however, are excessively susceptible to its influence and even these quantities may cause toxic symptoms. While scopolamine poisoning very rarely ends fatally, the symptoms are often extremely alarming. There are marked disturbances of intellection, sometimes an active delirium resembling that of atropine poisoning and at others simply complete disorientation. Many cases present marked somnolence, but in others this may be lacking. At times the pupils are dilated, the pulse rate accelerated and there is dryness of the mouth with a peculiar husky character to the voice apparently due to laryngeal paralysis, but these symptoms are often absent or very mild, presumably dependent upon the variety of the alkaloid. The condition rarely requires active treatment but if there is serious embarrassment of the respiration strychnine may be used; it is usually better not to employ any drugs for the relief of the delirium, although if very active small doses of paraldehyde and bromides may be employed.

Dose, one-two-hundredth to one-eightieth of a grain (0.0003–0.0008 Gm.).

SENEGA. U. S. (Br.)

SENEGA Seneg. [Senega Snakeroot, Seneca Snakeroot]

(sĕn'ẹ-gạ)

"The dried roots of *Polygala Senega* Linné (Fam. *Polygalaceæ*), without the presence or admixture of more than 5 per cent. of stems and other foreign matter." *U. S.* "Senega Root is the dried root of Polygala Senega, *Linn.*" *Br.*

Senegæ Radix, *Br.*; Rattlesnake Root, Mountain Flax, Senega or Seneca Root, Radix Polygalæ Virginianæ; Polygala de Virginie, *Fr. Cod.*; Radix Senegæ, *P. G.*; Senegawurzel, Klapper-Schlangenwurzel, *G.*; Poligala Virginiana, *It.*; Poligala de virginia (Raiz de), *Sp.*

Besides *P. Senega*, two other species have attracted some attention in Europe—*P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but, as they are not natives of this country, and are never used by practi-

tioners here, they do not merit particular notice.

A senega which was first used in Japan, and which has been referred by some writers to *P. japonica,* by others to *P. tenuifolia,* has been examined by Reuter, who finds in it 0.8 per cent. of resin, traces of methyl salicylate, and 8.8 per cent. of an oil which has somewhat the odor of patchouli. For description of other species of *Polygala* see Part II.

Polygala Senega has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple below, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright green on the upper surface, paler beneath, and sessile or short petiolate. The flowers are small and white, and form a close spike at the summit of the stem. The calyx is their most conspicuous part. It consists of five sepals, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed. The capsules are small, much compressed, obcordate, two-valved and two-locular, with two oblong-ovate, blackish, hairy seeds, slightly longer than the lobes of the caruncle. In *P. alba* Nutt, the seeds are silky and about twice the length of the caruncle lobes.

Polygala Senega extends over most of the United States and Southern Canada, east of the Rocky Mountains. At one time it was largely collected in Canada and the Northeastern Atlantic states; when this supply was exhausted, Kentucky and the States West and Southwest of it were invaded; then Wisconsin and the Northwestern States, from which with Western Canada the commerce at present derives its chief supply. There are two varieties of the plant, the typical *P. Senega,* the form found in the Northeastern United States, and the variety *latifolia* (T. and G.) which extends from Maryland and Pennsylvania to Michigan and Tennessee. This variety is distinguished by its height (from ten to twenty inches) and its very large, ovate or ovate-lanceolate leaves, which taper towards each end and attain a length of four inches. The root of commerce seems to be obtained from both varieties. It is brought into market in bales weighing from fifty to four hundred pounds. See True (*Ph. Era,* 1913, xlvi, p. 68).

Owing to the extensive use of senega considerable interest is manifested in the cultivation of the plant. Hood reports to have demonstrated that it can be successfully cultivated. (*Vermont Sta. Rept.,* 1907, p. 371.) It has also been grown by the Bureau of Plant Industry, U. S. Dept. of Agriculture.

Properties.—Senega is officially described as "usually in broken pieces; when entire slenderly conical, more or less tortuous, somewhat branched, from 3 to 15 cm. in length and from 2 to 10 mm. in thickness and bearing a few rootlets; crown knotty with numerous buds and short stem-bases; externally brownish-yellow, the crown rose-tinted, longitudinally wrinkled, frequently marked by a keel; fracture short, wood pale yellow, usually excentrically developed; odor peculiar, penetrating; taste sweetish, afterwards acrid. Under the microscope, transverse sections of Senega usually show a characteristic excentric development of wood, the central cylinder varying in outline from elliptical or ovate to irregularly fan-shaped, and being surrounded by an unevenly developed cortex which is thickest next to the broadest strands of wood and where the wood-wedges are narrow and the medullary rays very broad, the cortical parenchyma occupies a very narrow zone of the cross-section; in older roots a corky layer of from 4 to 5 rows of tangentially elongated, light yellowish or yellowish-brown cells; outer bark of about 20 rows of cells on one side of the root and only 10 or less on the other, the cells having slightly thickened walls and containing a colorless or pale yellow, amorphous substance, which is liberated in the form of large globules on the addition of a drop of potassium hydroxide T.S.; inner bark, the cells in radial rows, consisting of parenchyma, small groups of sieve tissue and medullary rays, the latter from 1 to 3 cells wide; all the cells in this zone show a collenchymatous thickening of the walls and contain an amorphous substance similar to that found in cells of the outer bark; woody layer of tracheæ with bordered pores, wood-fibers with oblique simple pores, tracheids, and medullary rays, the latter being rather indistinct and resembling the wood-fibers; tissues of the central layer of wood colored yellowish- or reddish-brown on the addition of a drop of potassium hydroxide T.S. The powder is yellowish-gray to light yellowish-brown, odor penetrating, slightly sternutatory; when examined under the microscope it exhibits a mixture of fragments of parenchyma containing oily globules and wood-fibers with tracheæ; wood-fibers, non-lignified and with oblique simple pores, from 0.175 to 0.25 mm. in length; tracheæ with simple and bordered pores and about 0.175 mm. in length; medullary ray cells somewhat lignified and with large simple pores. Extract 10 Gm. of powdered Senega by means of a Soxhlet apparatus, using 50 mils of ether containing 2 drops of hydrochloric acid. Continue the extraction during four or five hours and then add sufficient ether to make the liquid measure 50 mils. Take 25 mils of this solution and evaporate it on a water bath to dryness; the residue weighs not less than 0.3 Gm., and upon dissolving it in 10 mils of chloroform, transferring the solution to a test tube and adding 5 mils of sulphuric acid to form an underlying layer, a reddish-brown color is produced at the zone of contact, and the sulphuric acid shows a slightly green fluorescence after the mixture has stood for twenty-four hours. Pour 10 mils of the original ethereal solution into a beaker containing 10 mils of water and warm the mixture on a water bath until the ether has evaporated; the aqueous solution, upon filtering and adding a few drops of ferric chloride T.S.,

becomes a bright pinkish purple. Senega yields not more than 5 per cent. of ash." *U. S.*

"Greyish or brownish-yellow, slender, usually from five to ten centimetres long, with a knotty crown bearing the bases of numerous, slender, aerial stems; frequently curved or contorted, sparingly branched, keeled, sometimes transversely wrinkled. Fracture short. In transverse section, a horny translucent cortex free from starch grains and a white, often irregularly developed, wood. Characteristic odor; taste at first sweet, afterwards acrid." *Br.*

Holm describes the pharmacognosy of senega root and the morphology of the plant in *M. R.*, 1907, xvi, p. 155. Hartwich has made a very interesting observation in that he has found starch occasionally present in official senega. (*Apoth.-Ztg.*, xxvi, p. 84.) Hartwich has also described two false senegas. (*S. W. P.*, xlvi, pp. 537 and 749.) The pharmacognosy of the drug has been well elaborated by Tunmann in *Ph. Zentralh.*, xlix, p. 61. Muller describes and figures senega and a number of the drugs that have been used as adulterants of this drug or as occasional contaminations. (*Pharm. Praxis.*, vii, p. 309.)

Senega root varies somewhat in appearance according to the locality from which it is derived, and local varieties are recognized in commerce. In *Southern senega* the roots are very small, while in *Manitoba senega* they are large and thick, dark in color, and often have purple markings about the crown. The official senega is often known in commerce as *Southern senega,* or *small senega,* the roots seldom attaining the size of an ordinary lead-pencil, and four to five hundred of the dried roots being required to make a pound.

Since 1870 the so-called *Northern, White, False,* or *Large senega* has been sent into the American market from Wisconsin, Minnesota, and further west. It is much larger than true senega, probably eighty to one hundred to the pound. The knot at the top of the root is from one to three inches in diameter; below it the root abruptly contracts to from half an inch to an inch in diameter; it is usually from eight to ten inches long, more fleshy and much less contorted than true senega, nearly free from small rootlets, but breaking up below into from four to eight descending branches; very light-colored, with the ligneous portion thick and regular, and in the circular outlines of the section, with the keel rudimental or not rarely altogether absent. The taste is similar to that of true senega, but somewhat more mucilaginous and less rapidly acrid. In structure, false senega root is very similar to the true root; it has, indeed, been asserted that there are anatomical differences between the two senegas, but O. Linde (*P. J.*, xvi, 724) has been unable to make out any such differences. According to L. E. Sayre (*A. J. P.*, Sept., 1897), it is not possible to distinguish the two drugs when powdered. For description of the roots of a number of species of Polygala see *Flora*, Jan., 1886, and *D. C.*, 1901, 26. False Senega was thought to be the product of *Polygala Boykinii* Nuttall, or of *P. alba* Nuttall, whose habitat extends from the mountains of Texas to western British America, but Farwell (*M. R.*, 1907, xvi, 221) believes it is from the *P. Senega*, as it has the characteristic keel-like ridge of the official drug. The properties of senega as well as the medicinal virtues of the root, are extracted by boiling water and by alcohol. Diluted alcohol is an excellent solvent.

Senega root was analyzed by Gehlen, Peschier of Geneva, Feneulle of Cambray, Dulon d'Astafort, Folchi, and Trommsdorff, and subsequently by Quevenne. The virtues of senega appear to reside chiefly, if not exclusively, in the acrid principles called *senegin,* $C_{17}H_{28}O_{10}$, and *polygalic acid,* $C_{19}H_{30}O_{10}$. These principles resemble saponin very closely and are recognized as distinct. Quevenne obtained polygalic acid by the following process: Powdered senega is exhausted by alcohol of 33°, and so much of the alcohol is distilled off as to bring the resulting tincture to the consistence of syrup. The residue is treated with ether in order to remove the fatty matter. The liquid upon standing deposits a precipitate, which is separated by filtration and is then mixed with water. To the turbid solution thus formed alcohol is added, which facilitates the production of a white precipitate, consisting chiefly of polygalic acid. The liquid is allowed to stand for several days, that the precipitate may be fully formed. The supernatant liquid being decanted, the precipitate is drained upon a filter, and, being removed while yet moist, is dissolved by the aid of heat in alcohol of 36°. The solution is boiled with purified animal charcoal, and filtered while hot. Upon cooling, it deposits the principle in question in a state of purity. Thus obtained, polygalic acid is a white powder, inodorous, and of a taste at first slight, but soon becoming pungent and acrid, and producing a very painful sensation in the throat. It is fixed, unalterable in the air, inflammable, soluble in water slowly when cold and rapidly with the aid of heat, soluble in all proportions in boiling absolute alcohol, which deposits most of it on cooling, quite insoluble in ether and in the fixed and volatile oils, and possessed of the properties of reddening litmus and neutralizing the alkalies. Quevenne found it, when given to dogs, to occasion vomiting, and much embarrassment in respiration, and in large quantities to destroy life. Dissection exhibited evidences of inflammation of the lungs, and frothy mucus was found in the stomach, œsophagus, and superior portion of the trachea, showing the tendency of this substance to increase the mucous secretion, and explaining in part the beneficial influence of senega in croup. (*J. P. C.*, xxii, 449, and xxiii, 227.) Bolley showed that this active principle was resolvable by hydrochloric acid into glucose and a peculiar substance called *sapogenin.* Rochleder (*Chem. Cb.*, 1867, p. 925) confirmed this view of the identity of polygalic acid and saponin.

Christophson (*J. P. C.*, 1874) and Schneider (*A. Pharm.*, [3], 7, 394) have thoroughly

established the existence of saponin in senega root. According to the researches of Trommsdorff and Schneider, saponin is contained solely in the bark, the woody tissues being inert. (See *Quillaja*, p. 1035.) L. Reuter (*A. Pharm.*, 1889, 309 and 452) finds that the constituents of senega root are fixed oil and resin, traces of volatile oil (a mixture of valeric ether and methyl salicylate), sugar (7 per cent.), which seems to develop to a greater extent upon standing, senegin or saponin (from 2 to 5 per cent.), yellow coloring matter, and malates. The quantity of methyl salicylate varied in different samples from 0.25 to 0.33 per cent. See also Schroeder's analysis. (*A. J. P.*, 1896, 178.) Methyl salicylate occurs in very many, if not all, of the species of the genus Polygala. (See paper by Kremers and James, *Ph. Rev.*, xvi.) Kain (*Ph. Ztg.*, 1898, 562) states that he has discovered a lævo-rotatory glucoside distinguished from saponin by its mild taste, solubility in absolute alcohol, and in its not giving a precipitate with barium hydroxide.

Senega yields its virtues to water, cold or hot, and to boiling alcohol, and the extracts obtained by means of these liquids have the sensible properties of the root. But under the influence of heat a portion of the acrid principle unites with the coloring matter and coagulated albumen, and thus becomes insoluble in water. In forming an aqueous extract, the infusion should be prepared by percolation, as it is thus most concentrated, and consequently requires less heat in its evaporation. In preparing the infusion, the temperature of the water should not exceed 40° C. (104° F.). Experience has thoroughly proved the value of the use of an alkali in small proportion in making galenical preparations of senega, it prevents gelatinization and combines with the active principles. (See *Fluidextractum Senegæ*, page 499.)

The roots of *Panax quinquefolius* L., or ginseng, were at one period frequently mixed with those of senega, but are easily distinguishable by their shape and taste. The roots of *Gillenia trifoliata* (L.), Moench., and *Asclepias Vincetoxicum* L. (*P. J.*, ix, 411), and of *Triosteum perfoliatum* L. (see Part II), are noted as occurring in commercial senega; they are readily detected by the absence of the keel-like line.

Uses.—Senega owes what therapeutic virtues it possesses to its saponins. (See *Quillaia.*) These by their local irritant action upon the mucous membrane of the stomach tend to cause nausea, thereby increasing the secretions of the sweat glands and especially of the bronchial glands. For this reason the drug has been used as an expectorant in various forms of *bronchitis* and in *asthma*. In overdose it is capable of acting as an irritant poison producing violent vomiting and purging. Polygalic acid may be employed in doses of from one-fourth to one grain (0.016–0.065 Gm.), administered in the form of either pill or capsule.

For a formula for its preparation, see also *A. J. P.*, 1860, 150.

Dose, from fifteen to twenty grains (1.0–1.3 Gm.).

SENNA. U. S. (Br.)

SENNA Senn.

(sĕn'nạ)

"The dried leaflets of *Cassia acutifolia* Delile, known in commerce as Alexandria Senna, or of *Cassia angustifolia* Vahl, known in commerce as India Senna (Fam. *Leguminosæ*), without the presence or admixture of more than 10 per cent. of stem tissues, pods, seeds and other impurities." *U. S.* "Senna Leaves are the dried leaflets of Cassia acutifolia, *Delile*, and of Cassia angustifolia, *Vahl.* Known in commerce as Alexandrian senna, and Tinnevelly senna." *Br.*

Sennæ Folia, *Br.;* Senna Leaves; Séné, *Fr. Cod.;* Feuilles de Séné, *Fr.;* Folia Sennæ, *P. G.;* Sennesblätter, *G.;* Sena, *It.;* Sen, *Sp.*

The plants which yield *senna* belong to the genus Cassia, of which several species contribute to furnish the drug. These were confounded by Linnæus and comprised in a single species, which he named *Cassia Senna.* Since his time the subject has been more thoroughly investigated, especially by Delile, who accompanied the French expedition to Egypt and had an opportunity of examining the plant in its native country. Besides the official species, it is probable that *C. lanceolata* of Forskhal and *C. æthiopica* of Guibourt contribute towards commercial senna. The leaves of a number of species of Cassia are utilized like senna leaves in the respective countries in which they grow, among which may be mentioned *C. marilandica* L.; *C. cathartica* Mart.; *C. rugosa* Don.; *C. splendida* Vog.; *C. lævigata* Willd.; *C. multijuja* Rich.; *C. Chamæcrista* L.; and *C. montana* Hayne. Farwell asserts that *Cassia marilandica* and other American species of Cassia have been offered in large lots and sold as senna. (*M. R.*, xvii, p. 35.)

Cassia acutifolia is a small undershrub, two or three feet high, with a straight, woody, branching, whitish stem; but, according to Landerer, the senna plant attains the height of eight or ten feet in the African deserts. The leaves are alternate and pinnate, with glandless petioles, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, oval-lanceolate, acute, oblique at their base, nerved, from half an inch to an inch long, and of a yellowish-green color. The flowers are yellow, and in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and

divided into six or seven cells, each containing a hard, heart-shaped, ash-colored seed. *C. acutifolia* grows wild in great abundance in Upper Egypt, Nubia, Sennaar, and other parts of Africa. This species furnishes the greater part of the variety known in commerce by the name of Alexandria senna.

Cassia angustifolia as usually grown is annual, but with care it may be made to live through the year, and then assumes the character of an undershrub. It has an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lanceolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inward so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from 2 to 5 cm. The petioles are without glands; the stipules minute, spreading and semi-hastate. The flowers are bright yellow, and arranged in axillary and terminal racemes rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the summit, and 4 to 5 cm. long by about 1.5 cm. broad. This plant is found in Southern Arabia and on the coast of East Africa from Mozambique to the Somali land. It has been said to grow in the interior of India, and is cultivated at Tinnevelly for medicinal use.

Cassia obovata Colladon, possesses a rather shorter stem than that of *C. acutifolia*, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown color, and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. This species grows wild in Syria, Egypt, Senegambia, and Jamaica. (*P. J.*, Sept., 1867.) It has been cultivated successfully in Italy, Spain, and the West Indies. It is said to be no longer gathered for senna, although its leaflets and pods have been found in Alexandria senna.

C. lanceolata of Forskhal, found by that author growing in the deserts of Arabia, is admitted by Lindley and others as a distinct species. Some difference of opinion, however, exists upon this point. De Candolle considered it a variety of the *C. acutifolia* of Delile, from which it differs chiefly in having leaflets with glandular petioles, and, as Forskhal's description preceded that of Delile, he designated the species by the name of *C. lanceolata*. Forskhal's plant has been supposed by some to be the source of the India or Mocha senna, but the leaflets in this variety are much longer than those of *C. lanceolata*, from which the plant differs also in having no gland on the petiole. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of Abu-Arisch, whence it is taken by the Arabs to Mecca and Jedda. This is probably the *C. lanceolata* of Forskhal. It is highly probable that this species is the source of a variety of senna which has been brought to this market under the name of *Mecca senna*.

Cassia æthiopica of Guibourt (*C. ovata* of Mérat), formerly confounded with *C. acutifolia*, is considered by Lindley to be a distinct species. It grows in Nubia, Fezzan, to the south of Tripoli, and probably, according to Guibourt, throughout Ethiopia. It is from this plant that the *Tripoli senna* of commerce is derived.

Several varieties of this valuable drug are known in commerce. Of these, four have been received in America—the Alexandria, the Tripoli, the India, and the Mecca senna—but only two are recognized by the Pharmacopœia, which are officially described as follows:

"**Alexandria Senna.**—Usually unbroken, occasionally in fragments, leaflets inequilaterally lanceolate or lance-ovate, from 2 to 3.5 cm. in length and from 6 to 10 mm. in breadth, having extremely short, stout petiolules; acutely cuspidate, entire, subcoriaceous, brittle, pale green or grayish-green, sparsely and obscurely hairy, especially beneath, the hairs appressed; odor characteristic, taste somewhat mucilaginous and bitter. Pods few, broadly elliptical, somewhat reniform, dark green, thin and membranous.

"**India Senna.**—Leaflets usually unbroken, from 2 to 5 cm. in length and from 6 to 14 mm. in breadth, usually more abruptly pointed than those of Alexandria Senna, yellowish-green and smooth above, paler beneath; in odor and taste closely resembling Alexandria Senna. Pods few, elliptical, more or less reniform and from 4 to 5 cm. in length. Powdered Alexandria Senna is light green; when examined under the microscope it exhibits non-glandular hairs, 1-celled, conical, often curved, from 0.1 to 0.35 mm. in length, walls thick and papillose; calcium oxalate in rosette aggregates, from 0.009 to 0.01 mm. in diameter, and in 4- to 6-sided prisms, about 0.015 mm. in length, usually in crystal fibers; stomata broadly elliptical, about 0.02 mm. in long diameter. In India Senna the powder is slightly darker green than that of Alexandria Senna and the hairs are similar but relatively fewer. Mix 0.5 Gm. of powdered Senna with 10 mils of an alcoholic solution of potassium hydroxide (1 in 10), boil the mixture for about two minutes, dilute it with 10 mils of water and filter. Now acidify the filtrate with hydrochloric acid, shake it with ether; remove the ethereal layer and shake it with 5 mils of ammonia water; the latter is colored pinkish-red or bluish-red. Senna yields not more than 12 per cent. of ash. The yield of ash insoluble in hydrochloric acid is not more than 3 per cent. of the Senna taken." *U. S.*

"Pale greyish-green or yellowish-green, thin, brittle; usually from two to four centimetres long, the leaflets of Alexandrian senna being usually smaller than those of Tinnevelly senna; lanceolate, or oval-lanceolate, acute, entire, and unequal at the base. Surface finely pubescent

or nearly glabrous; veins on the under surface distinct. Epidermis of both surfaces consisting of polygonal cells and bearing one-celled, thick-walled, warty hairs together with stomata, each stoma being enclosed between two cells with their long axes parallel to the ostiole. The powdered Leaves greenish-yellow, exhibiting, in addition to the characteristic epidermis, stomata, and hairs, elongated palisade cells and grouped sclerenchymatous fibres accompanied by prismatic crystals of calcium oxalate. Ash not more than 12 per cent." *Br.*

1. ALEXANDRIA SENNA.—This variety of senna is gathered in extreme Upper Egypt and the Soudan, and thence sent to Assouan at the First Cataract of the Nile, whence it finds its way into commerce through Cairo, Suakim, Suez and Alexandria. Two crops are produced annually, one in the spring and one in the autumn. The plants are first cut, then dried, and then the stripped-off leaves and pods are packed in crude bales, in which several species of senna are represented in varying proportion, the predominating species being *C. acutifolia.* Formerly there was an intentional mixture of the product of Cassia acutifolia with the leaflets of *C. obovata,* brought from other parts of Egypt, and even from Syria, with the leaves of *Cynanchum oleæfolium* (*C. Argel* of Delile, *Solenostemma Argel* Hayne), known commonly by the name of *argel* or *arguel,* and sometimes with those of *Tephrosia apollinea* of De Candolle, a leguminous plant growing in Egypt and Nubia. According to M. Royer, the proportions in which the three chief constituents of this mixture were added together were five parts of *C. acutifolia,* three of *C. obovata,* and two of *Cynanchum.* Thus prepared, the senna was again packed in bales, and transmitted to Alexandria. But at present there is much more uniformity in the constitution of Alexandria senna. This variety of senna is often called in French pharmaceutical works *séné de la palthe,* a name derived from an impost formerly laid upon it by the Ottoman Porte. A parcel of Alexandria senna, as it was formerly brought to market, consisted of the following ingredients: (1) the leaflets of *C. acutifolia,* characterized by their acute form, and their length, almost always less than an inch; (2) the leaflets of *C. obovata,* known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; (3) the pods, broken leafstalks, flowers, and fine fragments of other parts of one or both of these species; (4) the leaves of *Cynanchum oleæfolium,* which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter color, and the regularity of their base. In this last character they strikingly differ from the genuine senna leaflets, which, from whatever species derived, are always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than the other, and at a different angle. Discrimination between this and the other ingredients is of some importance, as the Cynanchum must be considered an adulteration. It is said by the French writers to produce hypercatharsis and much irritation of the bowels, but was found by Christison and Mayer to occasion griping and protracted nausea, with little purgation. The flowers and fruit of the Cynanchum were also often present, the former white and in small corymbs, the latter an ovoid follicle rather larger than an orange-seed. Besides the above constituents of Alexandria senna, it occasionally contained leaflets of genuine senna, much longer than those of the *acutifolia* or *obovata,* equalling in this respect the Cynanchum, which they also somewhat resembled in form. They were distinguishable, however, by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their bases. The leaflets and fruit of *Tephrosia apollinea,* which have been an occasional impurity in this variety of senna, may be distinguished, the former by their downy surface, their obovate-oblong, emarginate shape, their parallel unbranched lateral nerves, and by being usually folded longitudinally; the latter, by its dimensions, being from an inch to an inch and a half long, and only two lines broad. In Europe, Alexandria senna was formerly adulterated with the leaflets of *Colutea arborescens* L., or bladder senna, and the leaves of *Coriaria myrtifolia* L., a poisonous plant of Southern Europe. An account of these plants is given in PART II.

The leaflets of the Coriaria are ovate-lanceolate, grayish-green with a bluish tint, and are readily known, when not too much broken up, by their strongly-marked mydrib and two lateral nerves running from the base nearly to the summit. They are free from hairs and do not contain crystals of calcium oxalate. Another addition to Alexandria senna has been detected by Lacroix of Mâcon, France, in the leaves of the *Globularia Turbith* (*Globularia Alypum* Linn.), which seem to have taken the place of the *Colutea arborescens,* because more closely resembling the senna leaflet. The leaves of the Globularia are spatulate, much enlarged towards the upper end, rounded at the extremity, but always terminating in a short sharp point. Besides, they are brown, thick, firm, and hard to the touch, while those of the Colutea are green, very thin, and soft. They have an acrid, very bitter taste, but are without nauseous odor. They are asserted to be cathartic, but milder than senna, and capable of being substituted for it in twice the dose. (*J. P. C.,* 4e sér., i, 413.)

The so-called *Aden senna* which Holmes states to be active, is composed of small, broad, not very acute, hairy leaves, and is believed to be obtained from *C. holosericea* Fres. A false senna from Madras has been identified by E. M. Holmes as the product of *Cassia montana* Hayne. The leaflets are about the size of the Tinnevelly senna, but are distinguishable by obtuse or rounded ends which are with distinct mucronate, the tip is, however, often broken off and absent

from individual leaves; by the obtuse angles of the lateral veins and by the presence of a well marked network of veins of the under surface; further, the color of the upper surface is distinctly browner than of the Tinnevelly leaflet. The whole leaves of *Cassia montana* have from 10 to 15 pairs of leaflets, while the Tinnevelly senna has only from 6 to 8 pairs. In the drug this character can usually be made out by noticing the number of scars on the rachis. For a microscopic description of powder, see H. G. Greenish, *P. J.*, lvi, 694. In detecting the adulteration of senna, the apothecary may avail himself not only of the general physical characteristics of the leaves, but also of the fact that while the senna leaf, containing no tannic acid, does not precipitate ferric chloride, most leaves used in adulteration do alter the ferric solution. The microscopic characteristics of the false leaves, though varying greatly, are almost always very different from those of senna. In the senna leaflets the epidermis from the upper and under surface is very similar. The stomata are numerous; the epidermal hairs are unicellular and deciduous, leaving, when detached, a base which has the appearance of an annular pad, around which the neighboring cells seem to radiate. The parenchyma of the cell has a thick epidermis, and is divided into three layers, the uppermost and lowest of which consist of palisade tissue, and are separated by a zone of very small, rounded, parenchymatous cells. Rosette aggregate crystals of calcium oxalate are scattered throughout the parenchyma, and prismatic crystals, one in each cell, occur clustered around the bast tissue of the principal veins.

For a microscopical description of Alexandria senna, see *Proc. A. Ph. A.*, 1882, p. 238.

2. India Senna.—This variety is in Europe sometimes called *Mocha senna,* probably because obtained originally from that port. It derives its name of India senna from the route by which it reaches us. Though produced in Arabia, it is brought to this country and Europe from Calcutta, Bombay, and possibly other ports of Hindostan. It consists of the leaflets of *Cassia elongata,* with some of the leafstalks and pods intermixed. The eye is at once struck by the great length (about two inches) and comparative narrowness of the leaflets, so that the variety may be readily distinguished. The pike-like shape of the leaflet has given rise to the French name of *séné de la pique.* Many of the leaflets have a yellowish, dark-brown, or blackish color, probably from exposure after collection, and the variety has commonly in mass a characteristic dull tawny hue. It is generally considered inferior in purgative power. Leaflets of a senna resembling the Indian were brought by Livingstone from Southern Africa, where the plant grows abundantly. (*P. J.*, xvii, 499.)

A variety of India senna has reached this country which is a product of Hindostan, being cultivated at Tinnevelly, and probably other places in the south of the Peninsula. The plant was originally raised from seeds obtained from the Red Sea, and is the same as that from which the common Indian senna is derived. The drug is exported from Madras to England, where it is known by the name of *Tinnevelly senna.* It is a fine unmixed variety, consiting of unbroken leaflets, from one to two or more inches long, and sometimes half an inch in their greatest breadth, thin, flexible, and of a fine green color. T. B. Groves, however, states as the result of his experiments that Tinnevelly senna contains only two-thirds as much of the active principle as does the Alexandrian. (*P. J.*, Oct., 1868, p. 292.)

Much study has been given to the question of distinguishing the powder of Alexandria and India senna by means of the microscope. (See papers by Sayre, *A. J. P.*, 1896, 1897; Schneider, *Am. Drug.*, 1897; Denniston, *Ph. Rev.*, vol. xvi.) As a result of these studies it is asserted that it is possible to take advantage of the greater hairiness of the Alexandria senna as a practical distinction, it being alleged that a fragment of the epidermis of Alexandria leaf contains twice as many hairs as does a similar sized shred of epidermis from the India senna. It is especially proposed to count the number of epidermal cells between two hairs or their scars, the average distance of the hairs from one another being in the Alexandria senna three epidermal cells, and in the India six cells. Advantage may also be taken of the difference in the neighboring cells of the stomata; in the majority of stomata, in each case, there are two of the neighbor-cells, but in India senna the proportion is one having three neighbor-cells to seven having two, and in the Alexandria the proportion is one having three to two having two.

3. Tripoli Senna.—Genuine Tripoli senna consists in general exclusively of the leaflets of one species of Cassia, formerly considered to be a variety of *C. acutifolia,* but now admitted to be distinct, and named *C. æthiopica.* The leaflets, however, are much broken up, and it is probably on this account that the variety is usually less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets, moreover, are shorter, less acute, thinner, and more fragile than those of *C. acutifolia* or Alexandria senna, and their nerves are much less distinct. The general opinion at one time was that it was brought from Sennaar and Nubia to Tripoli in caravans; but, it is reasonably asked by Fée, how could it be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert. It is probably collected at Fezzan, immediately south of Tripoli.

4. Mecca Senna is still imported under the name of *Arabian* or *Bombay Senna,* and is obtained from both wild and cultivated plants of *Cassia angustifolia.* The best drug is obtained from British India, great care being taken in its garbling. Much of the commercial article

is of a dark brown color. The leaflets are oblong-lanceolate, on the average longer and narrower than those of *C. acutifolia,* and shorter than those of *C. elongata.* The variety in mass sometimes has a yellowish or tawny hue, more like that of India than like that of Alexandria senna and may be the product of the *C. lanceolata* of Forskhal. Landerer speaks of a valuable variety of senna, characterized by the large size of the leaflets, and sold under the name of Mecca senna, which he says comes from the interior of Africa.

Commercial senna is prepared for use by *garbling,* or picking out the leaflets, and rejecting the leafstalks, the impurities, and the leaves of other plants. The pods are also rejected by some apothecaries. (See *Senna Fructus.*)

The market for senna is gradually changing. For years the drug used in the United States was imported from London or European ports. At the present time, the importations into the United States are largely direct from Egypt. The amount of senna annually exported is about 8000 bales of each of the varieties. Owing to the failure of the crops at certain seasons, the price of senna is very high, and what is known as "broken" senna is found upon the market and sold for the genuine article. This is done with the sanction of the government. In addition, what is known as "senna siftings," which contain large amounts of sand and other foreign matter, have been offered, and these have caused the government inspectors a large amount of trouble. There is considerable difference in the actual constituents of the two sennas, and it would seem advisable for the Pharmacopœia to restrict the drug to one species or else to include them under two separate titles. This principle has been followed by the German Pharmacopœia, as well as the Swiss Pharmacopœia, which restrict the official drug to the Indian senna, or that derived from *Cassia angustifolia.* Indian senna is known commercially as Tinnevelly senna, and this name should probably have been used in the Pharmacopœia. Alexandria senna is occasionally admixed with the leaflets of *C. obovata* Coll. (*Bull. Soc. roy. d. pharm. Brux.,* liii, p. 169). For description of these leaves, see page 991. In addition to admixture of senna with the leaflets of *Cassia marilandica* it is stated that the leaves of *Ailanthus glandulosa* have been found admixed. A very interesting and characteristic test for genuine senna depends upon the sublimation of its oxymethylanthraquinone, which is always a constituent, and this may be further confirmed by testing the sublimed material with a drop of one of the solutions of the alkalies which will show a red-colored test. (*Pharm. Prax.,* v, p. 435.)

Constituents.—The odor of senna is faint and sickly; the taste slightly bitter, sweetish, and nauseous. Water and diluted alcohol extract its active principles. Pure alcohol extracts them but imperfectly. (Bley and Diesel, *Ph. Cb.,* Feb., 1849, p. 126.) The leaves are said to yield about one-third of their weight to boiling water. The infusion is of a deep reddish-brown color, and has the odor and taste of the leaves. When exposed to the air for a short time, it deposits a yellowish insoluble precipitate, supposed to result from the union of extractive matter with oxygen. The nature of this precipitate, however, is not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues have been supposed to be impaired, but some experiments of B. Heerlein would seem to show that this opinion is incorrect. An extract prepared by boiling down an infusion, redissolving the residue, and again boiling down to a solid consistence, was found to operate actively in a dose equivalent to a drachm of the leaves. (*Ph. Cb.,* 1851, p. 909.) To diluted alcohol it imparts the same reddish-brown color as to water, but rectified alcohol and ether, digested upon the powdered leaves, become of a deep olive-green.

Lassaigne and Feneulle first isolated a substance to which they gave the name of *cathartin,* but it proved to be a mixture; Bley and Diesel (*Ph. Cb.,* 1849, p. 126) isolated a yellow coloring matter, which they called *chrysoretin,* but which Martius identified as *chrysophan;* Ludwig (*A. Pharm.* (2), cix, p. 42, and cxc, p. 69) obtained two bitter principles, *sennapicrin* and *sennacrol,* the first insoluble, the second soluble in ether; but the active purgative principle was first discovered in 1866 by Dragendorff and Kubly (*Viertelj. f. Prakt. Pharm.,* 16, pp. 96 and 337), who found it to be a glucoside of weak acid character, and named it *cathartic acid.* Thos. B. Groves, in 1868 (*P. J.,* 1869, p. 196), unaware of Dragendorff and Kubly's discovery, isolated the same principle, and found for it the same reactions. For a method of preparing cathartic acid, by Ralph Stockman, see *P. J.,* 1885, p. 740. Its formula is given as $C_{180}H_{96}N_2SO_{82}$, and by boiling its alcoholic solution with acids it yields *cathartogenic acid* and sugar. Gensz (*A. J. P.,* 1893, 334), who prepared it later by the method of Kubly and Stockman, gave the formula $C_{30}H_{36}NO_{18}$. It is amorphous, difficultly soluble in cold water, readily soluble in boiling water. The best solvent is a 30 to 40 per cent. alcohol; ether, benzene, chloroform, and petroleum ether are without solvent action. Alkalies with heat decompose it. It is prepared by partially precipitating with alcohol infusion of senna, concentrating to a syrupy consistence *in vacuo,* filtering, treating the filtrate with a large proportion of absolute alcohol, and repeatedly dissolving in water, and precipitating by alcohol the precipitate thus obtained. It is purified by submitting it (dissolved in moderately strong hydrochloric acid) to dialysis on a diaphragm of parchment paper, cathartic acid having strong colloidal properties. Groves found that ammonium cathartate purged moderately in the dose of three and three-quarters grains, with considerable griping, and that of certain mixed cathartates seven and a half grains purged violently, with much griping and sickness, and continued to act through most of a day. He considers four grains a fair dose.

It should be given in connection with an aromatic and a saline cathartic. *Magnesium cathartate* is soluble. The salts of this acid in aqueous solution are decomposed and rendered inert by long exposure to heat in contact with the air. (Groves, *P. J.*, Oct., 1868, 200–1.) Dragendorff and Kubly also found chrysophanic acid in small proportions, the two substances, *sennacrol* and *sennapicrin,* previously mentioned, and a peculiar non-fermentable saccharine principle, with the formula $C_{21}H_{44}O_{19}$, which they named *cathartomannite.* (*J. P. C.*, 4e sér., v.) A. Seidel proposes the name of *sennit* for catharto-mannite, and gives a process for its preparation in *A. J. P.*, 1885. In 1900 Tschirch and Hiepe made a comprehensive investigation of the chemical constituents of senna in which they found that the active principles belonged to the oxymethylanthraquinone group of glucosides, yielding emodin upon decomposition. From the aqueous percolate they extracted, besides *cathartic acid,* a crystalline body, giving the same reactions as *sennanigrin* and having the composition $C_{14}H_{10}O_5$. From the weak ammoniacal percolate they obtained *anthraglucosennin,* which, however, is composed of several distinct substances, for on treating it with ether, a portion enters solution and another remains undissolved; then the ether-soluble portion, if boiled with toluene and the solution poured on petroleum benzin, precipitates *sennaemodin,* while *sennachrysophanic acid* remains in solution and may be obtained on evaporation; the portion insoluble in toluene is a body which the authors have named *glucosennin.* Its composition agrees with the formula $C_{22}H_{18}O_8$, and it is possibly an emodin glucoside. From the portion of anthraglucosennin insoluble in ether, *sennaisoemodin* is obtained by treatment with acetone and shaking the resultant solution with petroleum benzin. The acetone solution retains a substance which the authors have named *sennarhamnetin.* Finally, the portion of anthraglucosennin remaining undissolved after treatment with ether and acetone is a black body which resembles in this and other respects aloe-nigrin. *Sennanigrin,* however, yields on treatment with alcoholic potassium hydroxide, sennaemodin and sennachrysophanic acid. (*A. Pharm.*, Aug. 31, 1900, 427, 448.)

Some results of experiments on the properties of senna which more particularly concern the pharmacist are noted in a paper contained in the *J. P. C.* (Janv., 1874, p. 80), and require to be mentioned here, because they tend to fix certain points which are left undetermined in the above statement. An extract made by evaporating in the air an aqueous infusion of senna possesses but partially the purgative properties of the leaves. If the extract be redissolved in a large quantity of water, and the solution be again evaporated, the extract now obtained will be quite inert. It follows that a prolonged decoction of senna destroys its cathartic powers. The presence of an alkali in the decoction increases the rapidity of the destruction. An infusion of senna in lime water, heated to the boiling point, and then deprived of lime by a stream of carbon dioxide, becomes inert. An infusion of senna, made to boil after the addition of potassium hydroxide, and then neutralized by an acid, is also inert. The mineral acids destroy the purgative powers of senna, but less energetically than the alkalies; the vegetable acids exercise the same power but feebly. Concentrated alcohol does not dissolve the active principle, which is soluble in cold water. It was Heerlein who first determined the complete want of purgative power in the pure alcoholic extract of senna. Nevertheless, this extract possesses in a high degree the odor and taste of senna, and, taken internally, without purging, imparts a deep-yellow color to the urine, which the alkalies change to red. The leaves exhausted by alcohol have all their purgative effect, but lose the power of affecting the urine so that an alkaline solution shall color it red. These facts prove that chrysophanic acid is not the purgative principle of senna. The fact that alcohol removes the odor and taste of senna without affecting its purgative action may sometimes be advantageously applied in cases in which the taste of senna is extremely offensive. L. Siebold, after experimenting with senna leaves washed with alcohol, arrived at the following conclusions: (1) Strong spirit does not remove any of the active principle from senna leaves; (2) the therapeutic action of cathartic acid is assisted by one or more of the constituents yielded by senna to strong alcohol, though these constituents produce no purgative effect when taken alone; (3) senna exhausted by alcohol is a reliable and pleasant purgative, but somewhat weaker in its action than the unexhausted leaves. Tutin reports the analysis of the water soluble portion of an alcoholic extract of Tinnevelly senna as containing (1) salicylic acid, (2) rhein ($C_{15}H_8O_6$), (3) kaempferol (1:3:4 trihydroxyflavonol), (4) aloe-emodin ($C_{15}H_{10}O_5$), (5) kaempferin ($C_{28}H_{30}O_6$), a glucoside of kaempferol, (6) glucosides of rhein and aloe-emodin, (7) a magnesium salt of an unidentified organic acid, (8) a sugar. The water insoluble portion contained (1) myricyl alcohol, (2) a phytosterol ($C_{27}H_{46}O$), (3) a phytosterolin ($C_{33}H_{56}O_6$), (4) palmitic and stearic acids, besides a small amount of essential oil.

Incompatibles.—Many substances produce precipitates with the infusion of senna, but it does not follow that they are all medicinally incompatible, as they may remove only inert ingredients. Cathartic acid is precipitated by infusion of galls and solution of lead subacetate. Lead acetate and tartar emetic which disturb the infusion, have no effect upon the solution of this substance.

Uses.—Senna was first used as a medicine by the Arabians. It was noticed in their writings as early as the ninth century, and the name itself is Arabic. Like the other cathartics of the anthraquinone series, its action is chiefly upon the lower bowel, and is therefore especially suitable in *habitual costiveness.* It increases the peristaltic movements of the colon by its local action upon the intestinal wall. The tendency to gripe may be obviated by combining it with aromatics

or with a saline laxative. The coloring matter of senna is absorbable, and twenty or thirty minutes after the ingestion of the drug it appears in the urine and may be recognized by a red color on the addition of ammonia. It is asserted also that the milk of nursing women acquires purgative properties after the administration of senna. Under the name of *cathartin* there is upon the market a mixture of the salts of cathartic acid which may be used in doses of from three to six grains (0.2–0.4 Gm.). *Sennax* is the name applied to the water-soluble glucoside of senna, and is marketed in tablets each one of which contains 0.075 Gm.

Dose, of senna, one-half to two drachms (2.0–7.7 Gm.).

SENNÆ FRUCTUS. Br.

SENNA PODS

(sĕn'næ frūc'tŭs)

"Senna Pods are the dried ripe fruits of Cassia acutifolia, *Delile,* and of Cassia angustifolia, *Vahl.*" *Br.*

Senna pods, while regarded as an adulterant in the U. S. P. IX in that the quantity is restricted, are official in the Br. Pharm. They are described as follows: "About five centimetres long, and from two to two and a half centimetres wide; broadly oblong or somewhat reniform; pale green; brownish in the centre above the seeds; very flat; rounded at the base, slightly mucronate at the apex. Pericarp papery. Seeds obovate-cuneate, flattened. Odor and taste slight." *Br.*

Uses.—They were preferred by the Arabian and mediæval physicians of Europe to the leaves, while Pereira states that they are much milder in their operation than the leaflets. This has been explained by the researches of E. F. Salmon, who has found that they contain about 25 per cent. more cathartic acid and emodin than the leaves, but no resinous principle or volatile oil. (*P. J.,* Oct., 1889.) The griping of senna being largely due to the resin, it is *a priori* to be expected that the pods would act more kindly than the leaves. A. W. Macfarlane has found this to be actually the case. From six to twelve pods for the adult, or from three to six for the young or very aged, infused in a claret-glass of cold water, in his experience, act very mildly but very thoroughly upon the whole intestine.

Dose, from one-half to one drachm (2.0–3.9 Gm.).

SERPENTARIA. U. S. (Br.)

SERPENTARIA Serpent. [Virginia Snakeroot, Texas Snakeroot]

(sĕr-pĕn-tā'rĭ-ă)

"The dried rhizome and roots of *Aristolochia Serpentaria* Linné, known in commerce as Virginia Snakeroot, or of *Aristolochia reticulata* Nuttall, known in commerce as Texas Snakeroot (Fam. *Aristolochiaceæ*), without the presence or admixture of more than 10 per cent. of the stems or other foreign matter." *U. S.* "Serpentary Rhizome is the dried rhizome and roots of Aristolochia Serpentaria, *Linn.,* and of Aristolochia reticulata, *Nutt.*" *Br.*

Serpentariæ Rhizoma, *Br.,* Serpentary Rhizome; Virginia Serpentaria, Virginia Snakeroot, Snakeweed, Pelican-flower, Snagrel, Sangrel, Radix Colubrina, Radix Viperina; Serpentary, Sangree; Serpentaire de Virginie, *Fr. Cod.;* Couleuvrée de Virginie, *Fr.;* Virginische Schlangenwurzel, *G.*

Many species of Aristolochia have been employed in medicine. Their supposed possession of emmenagogue properties has given origin to the name of the genus. Several of the nonofficial species are described in Part II.

Aristolochia Serpentaria is an herbaceous plant, with a short rhizome and numerous slender roots. Several stems often rise from the same rhizome. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently reddish or purple at the base. The leaves are oblong-cordate, acuminate, entire, of a pale yellowish-green color, and supported on short petioles. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downward so as nearly to bury the flower in the earth or decayed leaves. The tube of the calyx is curved like the letter S, enlarged at the base (ovary) and at its throat, the short limb being obtusely three-lobed. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is fleshy and from three to six-lobed. The fruit is an hexangular, six-celled capsule, containing several small flat seeds. The plant grows in rich shady woods from Connecticut west to Michigan and Missouri and south to Florida and Louisiana, abounding in the valley of the Ohio and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania, West Virginia, Ohio, Indiana, and Kentucky. It is usually in bales containing about one hundred pounds, and is often mixed with the leaves and stems of the plant, and with adhering dirt. For an account of *A. hirsuta,* see 18th ed., *U. S. D.,* p. 1222. On account of the rather large use of serpentaria the drug is becoming scarcer and some attempts at cultivation

have been made. (See *Proc. A. Ph. A.*, 1905, liii, p. 275, and *West. Drug.*, xxvii, p. 775.)

A. hastata (Nuttall.) Duchartre.—This is now considered to be nothing more than a variety of *A. Serpentaria,* from which it differs in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in the Carolinas, and elsewhere. Its root scarcely differs from that of the official plant, and is frequently mixed with it, as is proved by the presence of the characteristic hastate leaves in the parcels brought into market.

A. reticulata was probably first observed by Nuttall, as a specimen labelled "*A. reticulata,* Red River," in the handwriting of that botanist, is contained in the Herbarium of the Academy of Natural Sciences of Philadelphia. From a root similar to that of *A. Serpentaria* numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older stems are slightly villous, the young densely pubescent. The leaves, which stand on very short villous petioles, are round or oblong-cordate, obtuse, reticulate, very prominently veined, and villous on both sides, especially upon the veins. From the lower joints of the stem four or five hairy, jointed peduncles proceed, which bear small leafy villous bracts at the joints, and several flowers on short pedicels. The flowers are small, purplish, and densely pubescent, especially at the base and on the ovary. The hexangular capsule is deeply sulcate. This species grows from Virginia to Louisiana, Texas, Arkansas, and Oklahoma.

Properties.—Serpentaria is officially described as follows: "Rhizome in both commercial varieties oblique, subcylindrical, more or less curved, from 10 to 30 mm. in length and from 1 to 2 mm. in diameter; externally dark brown, upper portion with short stem-bases and from lower and lateral portions arise numerous, long, thin, nearly straight, yellowish-brown roots; fracture short; internally yellowish-white, wood with broad, excentric wedges; odor terebinthinate; taste bitter, aromatic. Under the microscope, transverse sections of the rhizome of both commercial varieties of Serpentaria show an outer layer of epidermal cells; a cortex of from 10 to 15 rows of parenchyma; inner bark sometimes showing strongly lignified bast-fibers, either single or distributed in a more or less interrupted circle; a xylem of broad wood-wedges separated by broad medullary rays about 8 cells wide, the walls being strongly lignified and with numerous simple pores; pith excentric, composed of polygonal cells, the walls being lignified and porous. Starch in the cells of cortical parenchyma, medullary rays and pith. The root in transverse section shows a compact, 4- to 6-rayed stele, and a large starch-bearing cortical area. The stem in transverse section shows an interrupted circle of from 6 to 10 fibro-vascular bundles, a cortex with a prominent continuous ring of strongly lignified cells, and a few non-glandular hairs. The powder is grayish-brown; when examined under the microscope it exhibits numerous starch grains, single and 2- to 4-compound, the individual grains being more or less spherical or plano-convex and frequently with a central cleft, from 0.003 to 0.014 mm. in diameter; lignified elements numerous, consisting of tracheæ, wood-fibers, medullary ray cells and pith cells; a few non-glandular hairs of the stem are occasionally present." *U. S.*

"Rhizome of Aristolochia Serpentaria tortuous and slender, about two centimetres long and three millimetres thick; on the upper surface the remains of slender, aerial stems, and on the under surface numerous wiry interlacing roots, often about seven centimetres long. Both rhizome and roots dull yellowish-brown. Characteristic odor; taste strong, camphoraceous, bitter. Ash not more than 10 per cent. Rhizome and roots of Aristolochia reticulata resemble the foregoing, but are longer and thicker, and the roots are straighter." *Br.*

Holm has published an illustrated article on the pharmacognosy of serpentaria, including the morphology of the stems and leaves. (*M. R.*, xvi, p. 276.)

Texas serpentaria contains a larger percentage of volatile oil than does the other variety of the drug. The color of serpentaria, which in the recent root is yellowish, becomes brown on keeping.

The roots of *Spigelia marilandica* are sometimes found associated with serpentaria. They may be distinguished by the absence of the bitter taste, and, when the stem and foliage are attached, by the peculiar character of these parts. (See *Spigelia.*) We have seen the young roots of *Polygala Senega* mixed with serpentaria. Independently of their difference in odor and taste, they may be distinguished by being simple, and by a projecting line running from one end to the other of the root. Another adulteration was detected by P. S. Milleman of Chicago, who found in a parcel a large quantity of "golden seal" (*Hydrastis canadensis*). The rhizomes, with rootlets attached, were from a quarter of an inch to an inch in length, and about one-eighth of an inch in diameter, but at the present time (1917) on account of the high price of senega and hydrastis neither admixture is likely to occur.

The root yields all its virtues to water and alcohol, producing with the former a yellowish-brown infusion, with the latter a bright greenish tincture, rendered turbid by the addition of water. Chevallier found in the root a volatile oil, a yellow bitter principle, soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Bucholz obtained from 1000 parts, 5 of a green fragrant volatile oil, 28.5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of lignin, and 144.5 of water. The active ingredients are probably the volatile oil and the yellow bitter principle of Chevallier, which that chemist considers analogous to the bitter principle of quassia; alkaline solution of cupric tartrate shows, moreover, the presence of a glucose sugar. The volatile oil

passes over with water in distillation, rendering the liquid milky, and impregnating it with the odor of the root. The volatile oil has been carefully investigated by J. C. Peacock (*A. J. P.*, 1891, 257). He found it to contain a terpene, $C_{10}H_{16}$, boiling at 157° C. (314.6° F.), of sp. gr. 0.865 (probably pinene); a compound ester boiling at 211° C. (411.8° F.), sp. gr. 0.9849, which on saponification yielded borneol, $C_{10}H_{18}O$, and a crystalline acid; a fraction boiling at from 239° to 240° C. (462.2°–464° F.), sp. gr. 0.9888, and of the composition $C_{18}H_{20}O$; and some green or bluish-green fluorescent oil in small quantity, which decomposes even when distilled under reduced pressure. The borneol ester constitutes about 60 per cent. of the oil. A principle called *aristolochine*, obtained from *A. Clematitis* and the roots of *A. rotunda* and *A. longa*, was investigated by Jul. Pohl. (*A. E. P. P.*, xxix.) He obtained it as a yellow crystalline mass, soluble in chloroform, ether, acetone, acetic anhydride, and alcohol, insoluble in petroleum benzin, benzene, and carbon disulphide, almost insoluble in cold water, slightly soluble in hot water. An ultimate analysis gave for its composition $C_{32}H_{32}O_{13}N$. O. Hesse obtained from the root of *Aristolochia argentina* an alkaloid to which he gives the name *aristolochine*, but has furnished no formula; a principle, *aristolin*, $C_{15}H_{28}O_3$; *physosterin palmitate*, in white scales, fusing at 82° C. (179.6° F.); and a mixture of acids to which he gives the names *aristic acid*, $C_{18}H_{18}NO_7$, *aristidic acid*, $C_{17}H_{10}(CH_3)NO_7$, and *aristolic acid*, $C_{15}H_{13}NO_7$.

The resinous *aristinic* acid has been obtained from a number of species of the genus *Aristolochia*, notably by Walz from *A. Clematitis*, by Chevallier from *A. Serpentaria*, by Dymock and Warden from *A. indica*, by Hesse from *A. argentina*, by Hooper from *A. bracteata*. Hooper has also obtained a closely alied, if not identical, resinous acid from the aristolochiaceous plant *Bragantia Wallichii*, besides an alkaloid, which, under the name of *Alpam*, has long been used in Western India as an antidote to snake venom. The allied species, *Bragantia tomentosa* of Blume, is said to be employed in Java as an emmenagogue.

Uses.—Serpentaria is a feeble stimulant tonic. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomiting and dysenteric tenesmus. It has been recommended in *intermittent fevers*, and may be serviceable as an adjunct to quinine. It is sometimes given in *dyspepsia*. The dose of fluidextract is from twenty minims to half a fluidrachm (1.3 to 1.8 mils). According to Pohl, aristolochine in sufficient dose produces in the higher animals violent irritation of the gastrointestinal tract and of the kidneys, with death in coma from respiratory paralysis.

Dose, fifteen to thirty grains (1 to 2 Gm.).

SERUM ANTIDIPHTHERICUM, U. S.

ANTIDIPHTHERIC SERUM Ser. Antidiph. [Diphtheria Antitoxin]

(sē'rŭm ăn'tĭ-dĭph-thĕr'i-cŭm)

"A fluid, having a potency of not less than 250 antitoxic units per mil, separated from the coagulated blood of the horse, *Equus Caballus* Linné (Fam. *Equidæ*), or other large domestic animal, which has been properly immunized against diphtheria toxin. It must be kept in sealed glass containers in a dark place, at a temperature between 4.5° and 15° C. (40° and 59° F.)" *U. S.* "The blood serum of horses which have been immunized against the diphtheria poison." *P. G.*

Serum Antidiphthericum, *P. G.;* Diphtherie-heil-serum, *G.;* Serum antidiphterique, *Fr.;* Siero antidifterico, *It.;* Suero antidifterico, *Sp.*

The antitoxic property of the blood serum of animals immunized by the inoculation of bacterial toxins was discovered in 1890 by Behring and Kitasato (*D. M. W.*, Nos. 49, 50, 1890). The great practical therapeutic value of diphtheria antitoxin was demonstrated independently by Behring and Roux and announced in papers read before the International Congress of Hygiene and Demography which met in Budapest in 1894.

Only the serum of the blood is used in medicine for prophylactic or curative purposes, although other body juices contain the active principle. The antitoxin has never been isolated in pure form. It is precipitated with the globulins and is believed to be allied to the enzymes. The antitoxin globulin retains its properties more persistently than the allied globulins with which it is associated. That is, it is more resistent to deleterious influences, more stable and more soluble than the other globulins found in blood serum. As we lack definite knowledge of the true chemical nature of the active principle contained in antitoxic serums, the antitoxin is variously spoken of as antikörper (G.) or antibodies, free receptors (Ehrlich), cytases (Metchnikoff), etc. Of the several antitoxins known, diphtheria and tetanus antitoxins are the only ones recognized by the U. S. Pharmacopeia. These are the only ordinary diseases caused solely by a soluble toxin; in other words, in these two diseases, not the bacteria themselves, but the poison which they excrete, produce the severe symptoms and frequent fatalities. And these two toxins, in the animal body, each give rise to an antitoxin which may be therapeutically or prophylactically efficient. Each antitoxin is specific; that is, neutralizes the poison of the particular infection which was inoculated into a suseeptible animal to produce it. While diphtheria antitoxin is used for other diseases, it is specific only in neutralizing the poisons produced by the diphtheria bacillus. Diphtheria antitoxin is sometimes normally present in small amounts in the blood serum of horses, man, and other animals.

Preparation.—Diphtheria antitoxin is made

by injecting the diphtheria poison (toxin) into horses. The horses are injected either subcutaneously or intravenously; usually the former method is preferred. Horses are selected because, on account of their size, a large amount of blood may readily be obtained, and because the serum of the horse is more easily borne by the human organism in large quantities than that of some other animals. Behring originally employed dogs and sheep with success; Aronson preferred the goat; Roux was the first to use the horse.

The antitoxin is produced by a vital reaction of the cells of the body caused by the stimulation of the toxin. Just which cells of the body take most active part in the production of the antitoxin is not exactly clear. Metchnikoff believed this power lies almost solely with the phagocytes, while Ehrlich believed that any of the body cells, but especially the connective tissue cells, play the most important role. The followers of Ehrlich and Metchnikoff have built up two divergent schools of thought to account for antitoxin immunity. It is interesting to note that both schools place the nutrition and metabolism of the cell at the groundwork of antitoxin production.

The toxin is made by growing a virulent culture of the diphtheria bacillus in an alkaline nutrient bouillon at about 37° C. (98.6° F.). This culture, when five to seven days old, is filtered through unglazed porcelain or diatomaceous earth in order to remove the bacterial cells. The clear filtrate, containing the soluble poisons elaborated by the growth and multiplication of the bacilli, is the *diphtheria toxin.* The horse is inoculated with increasing amounts of the toxin. At first very small amounts are used, but even these usually cause a local and constitutional reaction, swelling and edema at the site of inoculation, fever and derangement of appetite. These symptoms pass away in a few days, when a larger quantity of toxin is then inoculated, and this process is continued until within a few months the horse is able to withstand the subcutaneous inoculation of as much as a liter of a strong toxin with perhaps less local and general disturbance than is caused by the first treatment with a very small fraction of this amount.

As the doses of toxin given to the horse increase, the amount of antitoxin in the blood gradually increases until, after three to six months of treatment, the horse's blood usually contains from 200 to 400 units of antitoxin to the milliliter. The production of stronger antitoxin serums depends upon the horse and not upon the treatment. Some horses react actively and produce very high potency serums for long times; others cannot be induced to give a serum containing more than 150 to 200 units per milliliter. After a variable period (from several months to years) the horse loses the power of reaction, so that despite active treatment the immunizing power of the blood serum steadily diminishes. The horse is bled from the external jugular vein by means of a trocar and cannula. The blood is drawn into long sterile cylindrical tubes or other vessels and allowed to clot. The clear serum collects and in a few days is drawn off by a pipette. This clear albuminous fluid, passed through a filter which excludes bacteria, constitutes the Serum Antidiphthericum of the Pharmacopœia.

Preservatives.—The antitoxin in the blood serum neutralizes the toxin when the two are brought into contact, but the antitoxic serum does not prevent the growth of the bacteria themselves. Diphtheria bacilli grow and multiply well in diphtheria antitoxic serum. In other words, diphtheria antitoxin is a good culture medium for bacteria of all kinds. The greatest care must therefore be taken to prevent contamination. The serum may be kept sterile indefinitely only by means of the most exacting bacteriological precautions. It is sometimes marketed without the addition of an antiseptic substance, but this practice has been largely discontinued for the following reasons: (1) The technic required to prevent slight accidental contamination during the process of preparation and bottling is arduous; (2) there is danger of the introduction of serious contamination by unskilled persons who use the serum; (3) the addition of a small amount of certain preservatives is harmless. The serums made by the American manufacturers generally contain cresol (0.4 per cent.) phenol (0.5 per cent.), or chloroform (to saturation).

Properties.—Antidiphtheric Serum is officially described as "A yellowish or yellowish-brown, transparent or slightly turbid liquid, with sometimes a slight granular deposit; nearly odorless, or having an odor due to the presence of an antiseptic used as a preservative.

"Antidiphtheric Serum gradually loses in potency, the loss in one year varying between 10 per cent. and 30 per cent. The serum must come from healthy animals, must be sterile, must be free from toxins or other bacterial products, and must not contain an excessive amount of preservative (not more than 0.5 per cent. of phenol or cresol, when either of these is used), and the total solids must not exceed 20 per cent. Serum of a lower potency than 250 units per mil must not be sold or dispensed. Only such Sera may be sold or dispensed as have been prepared and propagated in establishments licensed by the Secretary of the Treasury of the United States.

"The United States law requires that each container of Serum sold or dispensed by licensed establishments shall bear upon the label, in addition to the name of the serum, the name, address, and license number of the manufacturer, and the date beyond which the product cannot be expected to yield its specific results. The label must also contain the laboratory number of the Serum and the total number of antitoxic units claimed for the contents of the container.

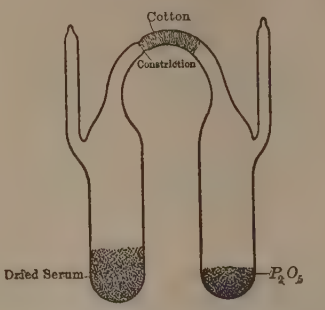
"The standard of strength, expressed in units of antitoxic power, shall be that established by the United States Public Health Service." *U. S.*

Tests.—The Immunity Unit. The strength

of antidiphtheric serum is expressed in immunity units. The unit is a measure of strength, not of volume. The official unit for this country is the antitoxic power contained in a definite quantity of the standard serum prepared and dispensed by the Hygienic Laboratory of the U. S. Public Health Service in accordance with the Law of July 1, 1902. The American standard was based on Ehrlich's normal serum made at the K. Institut für Experimentelle Therapie, Frankfurt a. Main, Germany. It is difficult to define the immunity unit in a brief sentence. A proper understanding of it may only be had from a study of the theoretical considerations involved (see "The immunity unit for standardizing diphtheria antitoxin," Bulletin No. 21, Hygienic Laboratory, U. S. Public Health Service, Washington, 1905.) The unit may be defined as the neutralizing power possessed by an arbitrary quantity of a diphtheria antitoxic serum kept under special conditions to prevent deterioration in an authorized laboratory. The test by which the strength of antitoxin contained in a unit is measured is a physiological one and depends upon the neutralization of the toxin by the antitoxin. This neutralization can only be determined by injecting the toxin and antitoxin mixtures into guinea pigs, which animals are highly susceptible to the diphtheria bacillus and its poisons.

The preparation and preservation of the standard serum is encompassed by many technical difficulties. A high-grade serum is selected. This is given a preliminary test to determine its potency. The serum is now reduced to dryness by evaporation in vacuo. Special apparatus is used to accomplish this evaporation quickly and at the same time to prevent contamination. The dried serum must be kept guarded under special conditions to prevent deterioration. The oxygen of the air must be excluded in order to retard the process of oxidation, which rapidly alters the antibodies, especially under the influence of light. The standard serum is, therefore, always kept under a vacuum and in absolute darkness in the Hygienic Laboratory of the U. S. Public Health Service. The serum must be perfectly dry. It is therefore kept under the influence of phosphoric anhydride, P_2O_5.

Further, the serum is kept in a specially built ice-box maintained at the constant temperature of 5° C. (41° F.) by means of circulating brine. The dried official serum is preserved in a small glass apparatus consisting of two parts connected by means of a glass tube, as shown in the accompanying illustration. The serum is placed in one portion of the apparatus and phosphoric anhydride, which is a very powerful dehydrating substance, in the other. The air is exhausted as much as possible by means of a high vacuum and the apparatus hermetically sealed. Several hundred such tubes are prepared, each one containing a weighed quantity of the powdered serum. From this arrangement, it will be seen that the powdered serum is kept dry, free from contact with the oxygen of the air, guarded against the action of light, and preserved at a constant low temperature. Once every two or three months, or whenever it is desired to prepare the standard solution, one of these bulbs is broken and 1 gramme of the serum carefully



U-shaped tubes used for preserving the standard serum. Half size.

weighed and dissolved in a solution made by mixing physiological saline solution (0.85 per cent.) one part, and pure glycerin two parts.

Testing the Standard Serum.—This glycerinated solution of blood serum is now accurately compared with previous standard solutions in terms of the immunity unit. This comparison is made by means of the test (L +) dose of toxin. The L + dose of a toxin is that quantity which when mixed with one immunity unit of serum is just able to kill a 250 gram guinea pig on the fourth day (about 96 hours). In the commercial testing of serums in order to have a coefficient of safety it is better to require the pig to live.

Testing the Toxin.—The toxin is a complex substance composed, according to Ehrlich, of several poisons, *e.g., toxin, toxoid, toxone* and *epitoxonoid.* The diphtheria toxin is first investigated biologically by adding varying quantities of the poison to the immunity unit and inoculating the mixtures into a series of guinea pigs. In this way, it is very evident, as Ehrlich has shown, that two limits, boundaries or zones are always shown, which are of the greatest importance in determining the nature and composition of the poison. Each of these limits is designated by the letter L, from *limes,* a boundary or zone. These limits are known respectively as L_o (O = nil) and L + (+ = death).

By L_o is meant that quantity of poison which just neutralizes or saturates one immunity unit as shown at the necropsy done forty-eight hours after the subcutaneous injection of the mixture into the guinea pig. The reaction at the site of inoculation at this examination must be hardly noticeable. Theoretically the L dose of toxin must unite with and neutralize just 200 "combining units" of antitoxin. A "combining unit" of antitoxin is in theory one two-hundredth of an immunity unit, and is supposed to contain enough antitoxin to just neutralize one fatal guinea pig dose of a pure toxin which is all poison without the comparatively inert (but antitoxin-neutralizing) toxoids and toxones. The

L_o dose, therefore, contains just 200 minimal lethal doses of a theoretically pure poison.

By L+ is meant the smallest quantity of toxin of which when mixed with one immunity unit of antitoxin there is left unneutralized a quantity to kill the animal on the fourth day. As defined by Ehrlich the L+ dose is that quantity of poison which, despite the antibodies contained in one immunity unit of serum, contains a sufficient excess of poison to cause the death of the guinea pig within the course of four days.

In studying the constitution of the diphtheria poison it is also necessary to determine its absolute toxicity with the greatest possible precision. The absolute toxicity of the diphtheria poison is expressed as the minimal lethal dose (MLD), sometimes spoken of as the minimal fatal dose (MFD), and occasionally simply as the lethal dose. The minimal lethal dose may be readily defined as the smallest quantity of toxin which will surely kill every guinea pig weighing 250 grammes in the course of four days, or at the latest, five days. As Ehrlich has pointed out, such a quantity may kill some of the animals sooner, that is, within thirty-six to forty-eight hours. A quantity of diphtheria poison that will kill every guinea pig, without exception, acutely within thirty-six to forty-eight hours contains more than the minimal lethal dose. The L+ dose is a much more definite and constant measure than the MLD. It does not show the irregularities or present the difficulties met with in determining the absolute toxicity of the poison. On account of the importance of the L+ and the L_o doses the following simplified tables taken from actual experiments are given to show just how the two are made:

Test to determine the L+ dose of a toxin.

	Result.
1 immunity unit + 0.19 mil toxin	Invariably causes late paralysis, never acute death.
1 immunity unit + 0.20 mil toxin	Sometimes causes late paralysis and sometimes acute death.
1 immunity unit + 0.21 mil toxin	Always causes acute death about the fourth day.
1 immunity unit + 0.22 mil toxin	Always causes acute death, usually on the second or third day.

The L+ dose of this toxin is, therefore, just 0.21 mil.

Tests to determine the L_o dose of a toxin.

	Result at autopsy 48 hours after inoculation.
1 immunity unit + 0.14 mil toxin	No visible reaction.
1 immunity unit + 0.15 mil toxin	No visible reaction.
1 immunity unit + 0.16 mil toxin	Slightest possible congestion about carbon particles or no reaction.
1 immunity unit + 0.17 mil toxin	Apparent reaction at site of inoculation.
1 immunity unit + 0.18 mil toxin	Injection and œdema at site.
1 immunity unit + 0.19 mil toxin	Injection and œdema at site.

The L_o dose of this toxin, therefore, is 0.16 mil.

Concentrated Serums.—At the present time the greater part of the diphtheria antitoxin used in the United States is concentrated. (See *Serum Antidiphthericum Purificatum*, U. S.). The processes used are due to Gibson and Banzhaf of the New York City Board of Health, and depend on precipitation of the globulin fractions with ammonium sulphate and subsequent purification and solution by dialysis. Sodium chloride and preservative are added and sterilization effected by filtration through a Berkefeld filter. The concentrated antitoxin solution thus prepared contains from two to three times the proportion of protein present in normal serum. Tests show that the artificially concentrated antitoxin kept in small vials in an ice box, preserves its potency as well as the ordinary antitoxin serum. Therapeutically the comparative results obtained are identical. Local irritation, rashes etc., seem to be less frequent and severe when this concentrated or "refined" antitoxin is administered, because for the same antitoxic unitage the product contains less of the protein substances which cause reactions.

Legal Requirements.—All diphtheria antitoxin sold in interstate commerce in this country must comply with the regulations made in accordance with the Law approved July 1, 1902, entitled "An Act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes." It is illegal to sell, barter, or exchange diphtheria antitoxin made in one State or Territory or the District of Columbia in another State or Territory or the District of Columbia unless the following salient points of the law have been complied with: 1. The product must be plainly marked with the proper name of the article contained therein: 2. The label on the package must plainly state the name and address of the manufacturer. 3. The package must be plainly labeled with the license number issued by the Secretary of the Treasury. 4. The date beyond which the contents cannot be expected, beyond reasonable doubt, to yield specific results, must be given on the label or package. The execution of the law rests with the Surgeon-General of the U. S. Public Health Service. Annual inspections of all licensed manufacturers are made by officers of the above named service. From time to time products of each licensed manufacturer are

bought on the open market and examined in the Hygienic Laboratory of the Public Health Service at Washington for purity and potency.

Uses.—Diphtheria antitoxin is a true specific for diphtheria if it is given in sufficient quantity and sufficiently early in the disease. The very unfavorable results obtained in England in 1895 in the treatment of *diphtheria* with serum were due, according to the report of the Lancet Commission (*L. L.*, July 19, 1896), in a great majority of cases, to the uses of serum too weak to produce therapeutic results. Experimental researches, for example, the very careful work of Madsen in Copenhagen in 1896, showed that for therapeutic purposes weak serum is of very little value. Equally disappointing results will be obtained if the antitoxin is administered after the toxine has damaged the cells. The early use of the remedy is of the greatest importance. No time should be lost, not even delay in waiting for bacteriological confirmation. As soon as diphtheria is suspected, 10,000 units of antitoxin should at once be injected into the subcutaneous or intramuscular tissue. The reliable figures given in the tables below, collected by Dieudonné (*Schutzimfung und Serum Therapie*) shows conclusively the great practical value of diphtheria antitoxin and emphasizes the importance of administering the remedy early.

Author.	Total number of cases.	Mortality per-centage.	First day	Second day.	Third day.	Fourth day.	Fifth day.	Sixth day.	After the sixth day.	Unknown.
Welch	1489	14.2	2.3	8.1	13.5	19.0	29.3	34.1	33.7	17.6
Hilbert	2428	18.3	2.2	7.6	17.1	23.8	33.9	34.1	38.2	....
Collective investigations of the American Pædiatric Society	5794	12.3	4.9	7.4	8.8	20.7	35.3	....	....	....
Collective investigations in the Austrian Health Department	1103	12.6	8.0	6.6	9.8	25.5	28.8	30.7	21.0	31.8
Collective investigations of the German Imperial Board of Health	9581	15.5	6.6	8.3	12.9	17.0	23.2	....	26.9	....

It will be seen from this table that every hour's delay lessens the chance of successful treatment. In cases treated within the first twenty-four hours of the onset of the disease the mortality is very small. "The bacteriological investigations of diphtheria in the United States" by William Welch (*Am. J. M. S.*, vol. 108, p. 427), show that 1115 cases of diphtheria treated in the first three days of the disease yielded a mortality of 8.5 per cent., whereas 546 cases in which the antitoxin was first injected after the third day of the disease a mortality of 27.8 per cent. resulted. Welch's statistics gathered from the hospitals of the world show conclusively that the antitoxin treatment produces "an apparent reduction of case mortality of 55.8 per cent." In Boston, a city which has suffered severely from diphtheria and where the antitoxin treatment has been particularly thorough, the reduction in the death rate has been striking. In the Boston City Hospital the death rate between 1888 and 1894 was only once below 40 per cent.; since 1895, when antitoxin was introduced, it has not once reached 15 per cent. (J. H. McCallum). Numerous statistics from all parts of the world upon the effect of the antitoxin treatment of diphtheria are practically unanimous in showing the good results of this remedy. The great value of diphtheria antitoxin is perhaps most strikingly seen in the laryngeal cases (*"membranous croup"*).

The standard curative dose is 10,000 units administered at once, though mild cases require less and severe ones more—particularly if not seen at the early stage. The entire amount needed should be given at one dose, intravenously if the case is urgent. A vein at the bend of the elbow may be punctured with the injection needle under aseptic precautions, and the antitoxin slowly introduced. Fortunately the serum is usually harmless even when injected in large quantities. The remedy should always be given by the hypodermic, intramuscular, or intravenous method. Strict asepsis must be observed. The liquid may be injected under the skin of any part of the body where the subcutaneous tissue is loose. The back, near the angle of the scapula, is a favorite site for inoculation; sometimes the flank or abdominal walls are chosen. The intramuscular route is more rapid and hence more effective than the subcutaneous; the heavy muscularature of the buttocks is usually chosen for this method. If improvement is not manifest after a few hours more antitoxin should be given, though this implies that the first dose was too small. It is the early administration rather than the large quantity which is most efficient. The exhibition of the remedy by the mouth or per rectum is practically valueless.

Diphtheria antitoxin is just as valuable for prophylaxis as for curative purposes. The passive immunity produced by the inoculation of the antitoxic serum does not last very long. The transitory nature of the immunity afforded by prophylactic injections is probably dependant upon the fact that the antitoxin-bearing horse serum, being a foreign protein, is broken down in the human body and excreted by the kidneys. The usual prophylactic dose is 1000 units. If the exposure to the infection continues the dose should be repeated in two weeks, but the second dose of antitoxin is more rapidly eliminated than the first. The antitoxin in the blood neutralizes the toxin elaborated by the bacilli growing on the mucous membrane of the throat, but has no

deleterious effect upon the bacteria themselves. The micro-organisms in this situation may continue to grow and remain virulent for months. This is the explanation of occasional failures of the antitoxin to prevent a subsequent attack of the disease.

Though the serum is usually harmless, sometimes urticaria, localized erythema and joint pains follow its administration. These symptoms commonly pass away without untoward consequences. The serum appears not to irritate the kidneys, even when injected into the tissues in very large amounts. Very rarely sudden death immediately follows the injection of diphtheria antitoxin. The cause of this unfortunate result is hypersusceptibility to horse serum. Such an accident may be avoided where it is feared on account of horse asthma or other evidence of sensitiveness, by the injection first of 0.1 mil of the serum and doubling the dose each half hour if no untoward symptoms develop, until the whole amount has been given. In any case, however, the danger from diphtheria is greater than the danger from serum reaction (anaphylaxis), and the antitoxin should not be withheld.

Diphtheric antitoxin gradually loses its strength, especially when kept under unfavorable conditions of light, temperature, etc. The loss in one year is usually from 10 to 30 per cent.; however, a serum will retain considerable antitoxic potency after years. Except for its diminished potency an old serum is quite as good as one freshly prepared; so that in an emergency or in order to save time an old serum may be administered, provided it remains uncontaminated.

Dose, prophylactic, 1000 to 2000 units; curative, 5000 to 20,000 units.

SERUM ANTIDIPHTHERICUM PURIFICATUM. U. S.

PURIFIED ANTIDIPHTHERIC SERUM Ser. Antidiph. Purif. [Antidiphtheric Globulins, Concentrated Diphtheria Antitoxin, Diphtheric Antitoxin Globulins, Refined and Concentrated Diphtheria Antitoxin]

(sē′rŭm ăn′-tĭ-dĭph-thĕr′ĭ-cŭm pū-rĭ-fĭ-cā′tŭm)

"A solution in physiological solution of sodium chloride of certain antitoxic substances obtained from the blood serum or plasma of the horse, *Equus Caballus* Linné (Fam. *Equidæ*), or other large domestic animal, which has been properly immunized against diphtheria toxin. After the serum or plasma from the immunized animal has been collected the antitoxin-bearing globulins are separated from the other constituents of the serum or plasma and dissolved in water; and sufficient sodium chloride is then added to make a solution containing from 0.6 to 0.9 per cent. of the salt. It has a potency of not less than 250 antitoxic units per mil. It must be kept in sealed glass containers in a dark place, at a temperature between 4.5° and 15° C. (40° and 59° F.)." *U. S.*

In the United States, this concentrated antitoxin has almost entirely supplanted the plain antidiphtheric serum, on account of the convenience of giving the same bulk in a smaller amount of fluid, and on account of the somewhat lessened tendency to urticaria after its use. Sterility is secured by careful filtration through bacteria-excluding filters.

For preparation, preservatives, tests, uses, see *Serum Antidiphthericum,* U. S.

Properties.—"A transparent, or slightly opalescent liquid, with sometimes a slight granular or ropy deposit, nearly odorless, or having an odor due to the presence of the antiseptic used as a preservative. The liquid is sometimes more or less viscous. The serum must come from healthy animals, must be sterile, must be free from toxins or other bacterial products, and must not contain an excessive amount of preservative (not more than 0.5 per cent. of phenol or cresol, when either of these is used), and the total solids must not exceed 20 per cent. Serum of a lower potency than 250 units per mil must not be sold or dispensed. Purified Antidiphtheric Serum must comply with the requirements for loss of potency, control, labeling, and standard for potency under *Serum Antidiphthericum.*" *U. S.*

Dose, prophylactic, 1000 to 2000 units; curative, 5000 and 20,000 units.

SERUM ANTIDIPHTHERICUM SICCUM. U. S.

DRIED ANTIDIPHTHERIC SERUM Ser. Antidiph. Sicc. [Dried Diphtheria Antitoxin]

(sē′rŭm ăn′-tĭ-dĭph-thĕr′ĭ-cŭm sĭc′cŭm)

"Dried Antidiphtheric Serum is obtained by the evaporation of either Antidiphtheric Serum or Purified Antidiphtheric Serum in a vacuum over sulphuric acid or other desiccating agent, or by passing over it a current of warm air freed from bacteria. It has a potency of not less than 4000 units per gramme. It must be kept in hermetically sealed, amber-colored glass containers free from air, at a temperature between 4.5° and 15° C. (40° and 59° F.), preferably in a dark place." *U. S.*

"Dried highly potent diphtheria antitoxin, which contains at least 5000 units in 1 gram, and has received no antiseptic or other addition; it is preserved in vacuum tubes." *P. G.*

Though the dried antitoxin retains its potency a much longer time than does the liquid serum, it is difficult to bring into solution for administration and the necessity of making such a solution strictly sterile without injuring the antitoxin imposes great inconvenience. For these reasons the dried product is little used in the United States.

Preparation, tests, uses, see *Serum Antidiphthericum,* U. S.

Properties.—"The Dried Serum is either in the form of orange or yellowish flakes or small lumps, or as a yellowish-white powder, without odor. The Serum is soluble in nine parts of distilled water, but the solution is opalescent and slightly viscous; it may be dissolved more readily in larger amounts of distilled water or physiological solution of sodium chloride. Immediately before use the Serum must be dissolved in

recently boiled and cooled distilled water under the most rigid aseptic conditions. The solution must be used immediately and if there should be any serum or solution remaining, it must be discarded. Dried Antidiphtheric Serum if kept as directed does not lose in potency, as does the liquid serum. It must comply with the requirements for control and labeling under *Serum Antidiphthericum* and the standard of strength, expressed in units of antitoxic power, shall be that established by the United States Public Health Service." *U. S.*

Preservative.—No antiseptic is added to the dry serum for the reason that bacterial multiplication cannot take place in a perfectly dry medium. Therefore, the double precaution must be taken that the serum be preserved entirely dry (hermetically sealed in vacuum), and that it be dissolved under rigid asepsis and used immediately.

Dose, prophylactic, 1000 to 2000 units; curative, 5000 to 20,000 units.

SERUM ANTITETANICUM. U. S.

ANTITETANIC SERUM Ser. Antitetan.
[Tetanus Antitoxin]

(sē'rŭm ăn-tĭ-tĕ-tăn'ĭ-cŭm)

"A fluid, having a potency of not less than 100 units per mil, separated from the coagulated blood of the horse, *Equus Caballus* Linné (Fam. *Equidæ*), or other large domestic animal, which has been properly immunized against tetanus toxin. It must be kept in sealed glass containers in a dark place, at a temperature between 4.5° and 15° C. (40° and 59° F.)." *U. S.*

"The blood-serum of horses which have been immunized against the tetanus poison." *P. G.*

Tetanus-Heilserum, *G.*; Serum Antitetanique, *Fr.*; Siero Antitetanico, *It.*; Suero Antitetanico, *Sp.*

The discovery of tetanus and diphtheria antitoxins was simultaneous, Behring, who worked principally on diphtheria, and Kitasato who worked on tetanus publishing their results together (*D. M. W.*, Nos. 49, 50, 1890) from the Hygienic Institute in Berlin under Robert Koch. In general the method of preparation is the same as that described under *Serum Antidiphthericum.* The purified and dried tetanus toxin is the most powerful poison known, the fatal dose for mice being as low as 0.000,000,05 gramme. There are at least two toxins produced by the tetanus bacillus—*tetano-spasmin,* which causes the muscular contractions typical of the disease, and *tetano-lysin,* which destroys the red corpuscles of the blood. The former is by far the more important, giving the symptoms of rigidity (*e.g.,* lockjaw), and tonic convulsions by which the disease is recognized in man and animals, and causing the high mortality. This poison is absorbed by the end-plates of the nerves in muscle, and travels up these motor nerves to the ganglion cells of the central nervous system. It is the passage along the nerves which occupies the greater part of the time of the incubation period.

Preparation.—The chief difference in method of preparation from that used in the case of diphtheria antitoxin lies in the fact that the tetanus bacillus belongs to the group of bacteria known as obligatory anaerobes, that is, those which thrive only in the absence of oxygen—and in the further fact that the poison formed by the tetanus bacillus is very unstable and rapidly loses in strength under ordinary conditions. The former difficulty is overcome by growing in deep vessels containing specially prepared broth which has been freshly heated to drive off the oxygen; and the latter by using the toxin soon after preparation or by storing it under special conditions.

Properties.—"A yellowish or yellowish-brown, transparent, or slightly turbid liquid with sometimes a slight granular deposit; nearly odorless, or having an odor due to the presence of the antiseptic used as a preservative. Antitetanic Serum gradually loses in potency, the loss being greater at higher than at lower temperatures. The Serum must come from healthy animals, must be sterile, must be free from toxins or other bacterial products, and must not contain an excessive amount of preservative (not more than 0.5 per cent. of phenol or cresol, when either of these is used), and the total solids must not exceed 20 per cent. Serum of a lower potency than 100 units per mil must not be sold or dispensed. Only such Sera may be sold or dispensed as have been prepared and propagated in establishments licensed by the Secretary of the Treasury of the United States. The United States law requires that each container of Serum sold or dispensed by licensed establishments shall bear upon the label, in addition to the name of the Serum, the name, address and license number of the manufacturer and the date beyond which the contents cannot be expected to yield its specific results. The label must also contain the laboratory number of the Serum and the total number of antitoxic units claimed for the contents of the container. The standard of strength, expressed in units of antitoxic power, shall be that established by the United States Public Health Service." *U. S.*

This serum was not included in the U. S. P. VIII because of the lack of a satisfactory standard. Since then, however, such a standard has been established. (The Standardization of Tetanus Antitoxin, by M. J. Rosenau and John F. Anderson, *Hyg. Lab. Bull.,* No. 43, U. S. P. H. S., March, 1908.) This method of standardization is distinct from any previously in use, but, since its adoption in this country, has come to be used to a large extent outside the United States as well. As with diphtheria antitoxin, the ultimate standard unit is a definite amount of dried serum kept under special condition at Washington. The technic of the preparation, storage, weighing, and solution of this antitoxin is the same as in the case of the diphtheria standard. The medium of measurement, however, is a standardized toxin which is likewise dried and preserved in vacuum tubes in the absence of moisture, and sent out to the establishments in various parts of the world

manufacturing tetanus antitoxin. On account of the hygroscopic quality of this dried poison and its extreme instability in the presence of moisture, it is necessary that the tubes be kept after opening in a vacuum desiccating chamber at a low temperature and protected from light. For each use the powder must be weighed quickly on delicate balances and computation made for gain in weight due to absorption of moisture. Any deterioration in the toxin may be detected by testing with the standard antitoxin or by ascertaining the minimal lethal dose (MLD), which is stated for each tube of toxin when sent out.

The animal used for testing tetanus antitoxin by the American standard is the guinea pig. The standard weight is 350 grammes, and the test dose of the toxin when mixed with one-tenth unit of antitoxin, should kill the guinea pig in about ninety-six hours.

Tetanus antitoxin, as well as all similar products, is tested for sterility by planting in suitable culture media and incubating for a number of days, and for presence of toxin, excess of preservative, or other deleterious content, by animal inoculation.

For other legal requirements, see *Serum Antidiphthericum,* U. S.

Uses.—Tetanus antitoxin has achieved its great success as a preventive rather than as a curative measure. Though in times of peace *tetanus* is not a common disease, the tetanus bacillus is ubiquitous and in its spore form, very long lived; its relative infrequence as a cause of sickness and death is due to the excellence of the bodily defenses against it. As explained above, the tetanus bacillus requires an absence of oxygen to thrive; this is not obtained unless the organism is introduced deep below the surface of the skin or under a tight covering, is accompanied by other organisms which absorb the oxygen, or has necrotic tissue as a nutrient. Even if so introduced, the natural antagonism of the body fluids or the wandering cells of the blood may render the invasion harmless. There is abundant evidence, however, that when the above conditions are favorable to its development, the tetanus bacillus produces a high mortality among wounded, and that this mortality is due to the toxin alone. Aside from the occasional tetanus infection when an ordinary wound is contaminated with dirt, and the cases of tetanus neonatorum now fortunately obsolete with the advent of asepsis in labor and in treatment of the umbilical cord, there are three large causes of tetanus: Fourth of July wounds—the laceration from explosion at short range driving contaminated material deep into the tissues; operation and wounds of horses—since horse manure is one of the most prolific sources of the tetanus bacillus; the wounds of warfare, particularly on cultivated terrain. In each of these three classes we have evidence of the value of tetanus antitoxin as a preservative.

In St. Louis, where tetanus had been common following Independence Day, the institution of serum treatment in 1904 was followed by entire absence of tetanus among those so treated. For the whole United States, where the growing use of tetanus antitoxin has been paralleled with decreasingly violent celebrations, the reduction in fatality is striking, the deaths from tetanus having fallen from 406 in 1903 to 1 in 1915, while the ratio of deaths from tetanus to total deaths from fireworks has fallen from 1 in 1.15 (406 out of 466) to 1 in 30, thus indicating that the tetanus prophylaxis has outstripped the general measures of safety.

The veterinary use of tetanus antitoxin in this country has repeatedly eliminated the disease among horses where it had previously been endemic. In France tetanus following operations on horses had been extremely common until the use of antitoxin was instituted, when the tetanus ceased except in the practise of those veterinarians who did not use the antitoxin.

All observers in the European war hospitals agree that when tetanus antitoxin was difficult to procure, in the early part of the war, the mortality from tetanus was high; but when properly standardized potent serum became available and was thoroughly administered, tetanus was rare. Though official statistics are not yet published, it seems clear from late military experience that in all wounds except the slight ones which heal quickly, the prophylactic injection of tetanus antitoxin should be repeated at weekly intervals until the wound is healed and wounded soldiers should receive a prophylactic dose when operated upon, even though the original wound had closed.

The results with tetanus antitoxin as a curative agent in the presence of the developed disease are not so brilliant, some surgeons questioning its value under these conditions. Intensive treatment, however, particularly intraspinal injection, apparently gives a lower death rate than is usual with tetanus treated without antitoxin. The technic for intraspinal medication is described under *antimeningococcus serum* in Part II.

For prophylaxis, then, 1500 units should be injected subcutaneously in case of any wound contaminated with dirt, caused by an explosive, or accompanied by severe mutilation of tissue. This injection should be repeated at weekly intervals until the wound has healed. It is also important that all such wounds receive thorough surgical attention, with wide opening and cleansing, removal of tissue likely to necrose, and repeated antiseptic dressings. For treatment, about 5000 units should be given intraspinally as promptly as possible, and 10,000 units intravenously at the same time; unless the serum is of low viscosity, it may well be diluted with sterile salt solution for intraspinous injection. The intraspinal dose may be repeated daily and the larger dose repeated subcutaneously a few days later to keep the blood saturated with antitoxin. The powdered antitoxin is sometimes used as a dusting powder on wounds, but absorption in this method is uncertain; chief reliance in prophylaxis must be placed in subcutaneous injection.

Hypersusceptibility to horse serum should be guarded against in the use of tetanus antitoxin as in the case of diphtheria antitoxin. The deterioration of the two serums is also similar.

SERUM ANTITETANICUM PURIFICATUM. U. S.

PURIFIED ANTITETANIC SERUM Ser. Antitetan. Purif. [Antitetanic Globulins, Concentrated Tetanus Antitoxin, Refined and Concentrated Tetanus Antitoxin, Tetanus Antitoxin Globulins]

(sē'rŭm ăn-tĭ-tē-tăn'ĭ-cŭm pū-rĭ-fī-cā'tŭm)

"A solution in physiological solution of sodium chloride of certain antitoxic substances obtained from the blood serum or plasma of the horse, *Equus Caballus* Linné (Fam. *Equidæ*), or other large domestic animal, which has been properly immunized against tetanus toxin. After the serum or plasma from the immunized animal has been collected, the antitoxin-bearing globulins are separated from the other constituents of the serum or plasma and dissolved in water; and sufficient sodium chloride is then added to make a solution containing from 0.6 to 0.9 per cent. of the salt. It has a potency of not less than 100 units per mil. It must be kept in sealed glass containers in a dark place, at a temperature between 4.5° and 15° C. (40° and 59° F.)." *U. S.*

As with diphtheria antitoxin, this concentrated serum is usually preferred to the unconcentrated on account of the reduction in bulk and the lessened amount of the proteins of horse-serum for a given unitage value.

Preparation, preservatives, tests, uses, see *Serum Antitetanicum,* U. S.

Properties.—"A transparent or slightly opalescent liquid, with sometimes a slight granular or ropy deposit; nearly odorless, or having an odor due to the presence of the antiseptic used as a preservative. The liquid is sometimes more or less viscous. The serum must come from healthy animals, must be sterile, must be free from toxins or other bacterial products, and must not contain an excessive amount of preservative (not more than 0.5 per cent. of phenol or of cresol, when either of these is used), and the total solids must not exceed 20 per cent. Serum of a lower potency than 100 units per mil must not be sold or dispensed. Purified Antitetanic Serum must comply with the requirements for loss of potency, control, labeling and standard for potency under *Serum Antitetanicum.*" *U. S.*

Dose, prophylactic, 1500 units; curative, 5000 to 20,000 units.

SERUM ANTITETANICUM SICCUM. U. S.

DRIED ANTITETANIC SERUM Ser. Antitetan. Sicc. [Dried Tetanus Antitoxin]

(sē'rŭm ăn-tĭ-tē-tăn'ĭ-cŭm sĭc'cŭm)

"Dried Antitetanic Serum is obtained by the evaporation of either Antitetanic Serum or Purified Antitetanic Serum in a vacuum, over sulphuric acid or other desiccating agent, or by passing over it a current of warm air freed from bacteria. It has a potency of not less than 1000 units per gramme. It must be kept in hermetically sealed amber-colored glass containers, free from air, at a temperature between 4.5° and 15° C. (40° and 59° F.), preferably in a dark place." *U. S.*

"Dried tetanus antitoxin which has received no antiseptic or other addition; it is preserved in vacuum tubes." *P. G.*

As with dried diphtheria antitoxin, dried tetanus antitoxin has the advantage of retaining full potency longer than the liquid forms, and the disadvantage of being difficult to bring into solution. The dried powdered tetanus antitoxin, however, has one additional use, as a local application to wounds; this treatment should be supplemented by subcutaneous injection of the liquid antitoxin or dissolved powder, since the amount absorbed from the wound is uncertain.

Preparation, tests, uses, see *Serum Antitetanicum,* U. S.

Properties.—"Dried Antitetanic Serum is either in the form of orange or yellowish flakes or small lumps, or a yellowish-white powder, without odor. The serum is soluble in nine parts of distilled water, but the solution is opalescent and slightly viscous; it may be dissolved more readily in larger amounts of distilled water or physiological solution of sodium chloride. For use, the serum must be dissolved in recently boiled and cooled distilled water under the most rigid aseptic conditions. The solution must be used immediately and, if there should be any serum or solution remaining, it must be discarded. Dried Antitetanic Serum if kept as directed does not lose in potency, as does the liquid serum. It is sometimes used as a dusting powder or for local application to infected wounds. It must comply with the requirements for control and labeling under *Serum Antitetanicum* and the standard of strength, expressed in units of antitoxic power, shall be that established by the United States Public Health Service." *U. S.*

Preservative.—No antiseptic is added to the dry serum for the reason that bacterial multiplication cannot take place in a perfectly dry medium. Therefore the double precaution must be taken that the serum be preserved entirely dry (hermetically sealed in vacuum) and that it be dissolved under rigid asepsis and used immediately.

Dose, prophylactic, 1500 units; curative, 5000 to 20,000 units.

SEVUM BENZOATUM. Br.

BENZOATED SUET

(sē'vŭm bĕn-zō-ā'tŭm)

"Prepared Suet, 1000 *grammes;* Benzoin, in coarse powder, 30 *grammes.* Melt the Suet, add the Benzoin, and maintain at a temperature of 60° C. (140° F.), for one hour, stirring frequently; strain, and stir until nearly cold. In

India, Benzoated Suet should be employed in making the official preparations for which Benzoated Lard (Adeps Benzoatus) is directed to be used." *Br.*

It is also official in the N. F. IV under the title *Sevum Benzoinatum* (see Part III).

SEVUM PRÆPARATUM. U. S., Br.

PREPARED SUET Sev. Præp. [Mutton Suet Sevum, U. S. 1890]

(sē'vŭm præ-pą-rā'tŭm)

"The internal fat of the abdomen of the sheep (*Ovis aries* Linné, Fam. *Bovidæ*), purified by melting and straining. Preserve Prepared Suet in well-closed vessels impervious to fat. It must not be used after it has become rancid." *U. S.* "Prepared Suet is the purified internal fat of the abdomen of the sheep, Ovis aries, *Linn.*" *Br.*

Sevum, *U. S.* 1890; Sebum Ovillum; Mutton-Suet, Prepared Mutton Tallow; Suif de Mouton, *Fr. Cod.*; Graisse de Mouton, *Fr.*; Sebum ovile, *P. G.*; Hammeltalg, Talg, Schöpsentalg, Unschlitt, *G.*; Grasso di Moutone, Grasso duro, *It.*; Sebo de carnero, *Sp.*

Suet is the fat of the sheep, taken chiefly from about the kidneys. It is prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water. Mutton suet is of a finer consistence, and requires a higher temperature for its infusion, than any other animal fat. It is very white, sometimes brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposits it upon cooling. It consists, according to Chevreul, of stearin, palmitin, and olein, containing approximately 70 per cent. of stearin and palmitin and 30 per cent. of olein. These principles are described under the *Olea Fixa* (page 727). It is officially described as "a white, solid fat, nearly inodorous, and having a bland taste when fresh, but becoming rancid on prolonged exposure to the air. It is insoluble in water or cold alcohol; it dissolves in 44 parts of boiling alcohol, in about 60 parts of ether, and slowly dissolves in 2 parts of purified petroleum benzin. From its solution in the latter, when allowed to stand in a stoppered flask, it slowly separates in a crystalline form. An alcoholic solution of Prepared Suet is neutral or slightly acid to litmus paper moistened with alcohol. Prepared Suet melts between 45° and 50° C. (113° and 122° F.) and congeals between 37° and 40° C. (98.6° and 104° F.). One Gm. of Prepared Suet, dissolved in 50 mils of hot alcohol, and a few drops of phenolphthalein T.S. added, requires not more than 0.6 mil of tenth-normal potassium hydroxide V.S. to produce a pink color (*free acid*). Saponification value: not less than 193 nor more than 200 (see Part III, Test No. 9). Iodine value: not less than 33 nor more than 48 (see Part III, Test No. 8)." *U. S.*

"Firm, white, unctuous. Nearly inodorous; taste bland. *Saponification value* 192 to 195; *iodine value* 33 to 46; *acid value* not more than 2.0; melting point 45° to 50° C. (113°–122° F.); *refractive index* at 60° C. (140° F.), 1.4490 to 1.4510. In India, Prepared Suet should be employed in making the official preparations for which Prepared Lard (Adeps Præparatus) is directed to be used." *Br.*

E. Dieterich examined a large number of samples of mutton and beef suet, and found that they were without exception acid and that neutral suet does not exist. The melting point of mutton suet is between 48.5° and 50.5° C. (119.3°–122.9° F.); that of beef suet, between 47.5° and 48° C. (117.5°–118.4° F.). The specific gravity of mutton suet lies between 0.937 and 0.952; that of beef suet, between 0.943 and 0.952. (*A. Pharm.*, 1887, 496.)

Off. Prep.—Sevum Benzoatum, *Br.*

SINAPIS ALBA. U. S.

WHITE MUSTARD Sinap. Alb. [Yellow Mustard]

(si-nā'pĭs ăl'bą)

"The ripe seeds of *Sinapis alba* Linné (Fam. *Cruciferæ*), without the presence or admixture of more than 5 per cent. of other seeds or other foreign matter. Preserve powdered White Mustard in tightly-closed containers." *U. S.*

Sinapis Albæ Semina, *Br.* 1898; White Mustard Seeds; Yellow Mustard Seed; Moutarde blanche, *Fr. Cod.*; Semen Erucæ, *P. G.*; Weisser Senfsamen, Weisser Senf, *G.*; Senape bianca, *It.*; Mostaza blanca, *Sp.*

Neither black nor white mustard is any longer official in the British Pharmacopœia.

Yellow or *white mustard* is a native of Europe and is extensively cultivated, being occasionally spontaneous, in the United States. The commercial supplies are obtained from England, Holland, Germany and California.

Properties.—The official description of white mustard is as follows: "Sub-globular, from 1.5 to 2.5 mm. in diameter; testa yellowish, nearly smooth; embryo yellowish, oily, with two large cotyledons; inodorous, taste mildly pungent, acrid. The powder is light yellowish or pale brownish-yellow, developing a slight odor when moistened; when examined under the microscope it exhibits numerous tissues of the embryo containing small aleurone grains and a fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S.; fragments of seed-coat comparatively few, nearly colorless, with small, characteristic stone cells and large epidermal cells, the outer walls being mucilaginous. The powder contains few or no starch grains. White Mustard does not yield allyl isothiocyanate upon distillation with steam (distinction from *Black Mustard*). White Mustard yields not more than 9 per cent. of ash." *U. S.*

For an illustrated monograph on the pharmacognosy of white mustard, see Winton and Moeller, "*Microscopy of Vegetable Foods.*" The only adulterant of white mustard are the seeds of the white Indian *colza*, obtained from *Brassica campestris* Sarson (L.) Prain. They are

distinguished in having a more pronounced ridge over the radicle. Under the microscope the seeds have an indistinct epidermis, the collenchymatous subepidermal layer is wanting, and the palisade cells are quite large compared with white mustard. For further information see *Sinapis Nigra.*

SINAPIS NIGRA. U. S.

BLACK MUSTARD Sinap. Nig. [Brown Mustard]

(sī-nā'pĭs nī'grą)

"The ripe seeds of *Brassica nigra* (Linné) Koch (Fam. *Cruciferæ*), without the presence or admixture of more than 5 per cent. of other seeds or other foreign matter. Preserve powdered Black Mustard in tightly-closed containers." *U. S.*

Sinapis Nigræ Semina *Br.* 1898; Black Mustard Seeds; Semina Brassicæ; Moutarde noire, *Fr. Cod.*; Moutarde, *Fr.*; Semen Sinapis, *P. G.*; Senfsamen, Schwarzer Senf.; Senape nera, *It.*; Mostaza (Semilla de), *Sp.*

Linnæus described two genera, Brassica and Sinapis, and subsequent botanists have greatly disagreed as to whether they should be considered identical or not. The revisers of the U. S. P. have adopted the opinion of Engler and Prantl and of Britton and Brown, that the two genera are distinct. The genus Sinapis differs from Brassica in that the pods of the former are terminated by a long, flat, sword-like beak, whereas in Brassica the beak is cylindrical or conical.

Common or black mustard (*Brassica nigra*), is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally toothed, those higher on the stem are smooth, and less lobed, and the uppermost are entire and narrow. The flowers are small, yellow, and stand closely together upon peduncles at the upper part of the branches. The pods are smooth, erect, nearly parallel with the branches, quadrangular, and furnished with a slender beak; seeds numerous, dark brown.

The white mustard is also annual. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged, with stiff hairs on both sides, and pale green. The flowers are in racemes, with yellow petals, and linear, green calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

Both sinapis alba and Brassica nigra are natives of Europe and cultivated in our gardens, and *B. nigra* has become naturalized in some parts of this country. Their flowers appear in June. The seeds are kept in the pharmacies, both whole and in the state of very fine powder as prepared by the manufacturers for the table. The latter is sometimes mixed with spices and ground into a smooth paste with water in a mill resembling a paint mill, and then is known as *French mustard.*

The seeds of *Brassica ibertifolia,* according to O. Harz, are sometimes sold as true white mustard seed. He examined some obtained from Bavaria, which had been returned by customers to the dealers on account of their bitter and disagreeable taste. He furnishes characteristic microscopical tests for distinguishing the false from the true mustard seed. His statement, however, that powdered white mustard seed when mixed with water is odorless, and that the false gives off a strong odor of essential oil of mustard, would seem to be a good reason, if correct, for preferring the false seed. (*P. J.,* 1887, 478.)

The *Brassica juncea* (L.) Coss. (*Sinapis juncea* L.), is extensively grown in India, and its seeds are largely exported to Europe. The same plant is also cultivated in Southern Russia. The seeds afford a very fine yellow mustard flour, and, according to Paul Birkenwald, yield 1.67 parts per hundred of volatile oil, against 1.89 parts per hundred by the true black mustard seed. (*S. W. P.,* 1888.)

Black mustard seeds are officially described as "ellipsoidal or irregularly spheroidal, from 1 to 1.6 mm. in diameter; testa deep reddish-brown, sometimes yellowish-brown and with a grayish tinge, minutely pitted or reticulate; embryo greenish-yellow or dark yellow, oily, with two large cotyledons; odor when dry, slight, on moistening very irritating; taste strongly pungent and acrid. The powder is light brown or greenish-brown; on moistening developing a strongly pungent, irritating, characteristic odor; when examined under the microscope it exhibits numerous tissues of the embryo, the cells containing small aleurone grains and a fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S.; fragments of seed-coat conspicuous, with large, polyhedral, dark yellow areas, enclosing small, yellowish stone cells, each of the latter with a dark lumen. The powder contains few or no starch grains. Black Mustard, upon distillation with steam, yields allyl isothiocyanate (distinction from *White Mustard*). Black Mustard yields not more than 9 per cent. of ash." *U. S.*

Both white and black mustard afford a powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called *flour of mustard,* or simply *mustard,* and is prepared by crushing and pounding the seeds and then sifting them, the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. Formerly it was adulterated with wheat flour colored by turmeric, to which cayenne pepper was added to render the mixture sufficiently hot. Pure mustard powder contains very few starch granules, but was formerly adulterated with farinaceous powders; the U. S. P. VIII required that White or Black Mustard should conform to the following test: "If 1 Gm. of powdered White (or Black) Mustard be exhausted by slow percolation with alcohol, and the marc mixed with 200 Cc. of water and

heated to boiling, and if, after cooling, sufficient cold water be added to make the mixture measure 1000 Cc., the addition of 4 Cc. of tenth-normal iodine V.S. should not produce a dark blue color (limit of *starch*)." *U. S. VIII.*

The epidermis of white mustard seeds contains a mucilaginous substance which is extracted by boiling water. An excellent basic monograph on the pharmacognosy of black mustard is that given by Winton and Moeller in "*The Microscopy of Vegetable Foods.*" Tschirch and Oliva have made a comparative study of the seeds of the Cruciferæ, with special reference to the variations found in the seed-coat of the several species of mustard. (*S. W. P.*, xliii, p. 614.) Spaeth gives the results of chemical and microscopical study of the mustards and some of their adulterants in *Ph. Zentralh.*, xlix, p. 698. Carles has also contributed a valuable article on the pharmacognosy of the different mustard seeds and the commercial varieties of mustard flour in *J. P. C.*, 1913, pp. 438 and 535. The most common adulteration of black mustard is *charlock*, which is the seeds of *Brassica arvensis* (L.) Ktze. This plant is especially abundant in the Northwestern part of the United States and the Dakota mustard contains varying mixtures of brown mustard and charlock. The presence of charlock is very easily determined by the use of a solution of chloral hydrate which changes the color of the palisade cells to a crimson red.

When bruised or powdered, both kinds of mustard impart their active properties wholly to water, but in a very slight degree to alcohol. They yield upon pressure a fixed oil, called *oil of mustard*, of a greenish-yellow color, little odor, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seeds. The fixed oil of mustard consists of the glycerin compounds of stearic, oleic, and *erucic* or *brassic* acid, $C_{22}H_{42}O_2$, a homologue of oleic acid. Small quantities of *behenic* acid, $C_{22}H_{44}O_2$, also occur in oil of black mustard. This fixed oil is a yellow non-drying oil of from 0.915 to 0.920 sp. gr. at 15° C. (59° F.), solidifying at from –12° to —16° C. (10.4–3.2° F.). It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, containing sulphur. Guibourt conjectured, and Robiquet and Boutron proved, that this oil does not pre-exist in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odor in the seeds when bruised in a dry state, and their pungency when water is added. It seemed reasonable to suppose that the reaction in this case was similar to that exercised by water upon bitter almonds (see *Amygdala Amara*), and this has been proved to be the fact by the experiments of Simon, Bussy, Boutron, and Frémy. The composition and peculiar decompositions of the volatile oil of black mustard have already been described. (See *Oleum Sinapis Volatile.*)

A principle was extracted by Will from white mustard seed, with the aid of alcohol. It has been named *sinalbin*, and has the formula $C_{30}H_{44}N_2S_2O_{16}$. It is decomposed, after the analogy of sinigrin (potassium myronate), into *acrinyl sulphocyanate*, C_7H_7OCNS, *sinapine bisulphate*, $C_{16}H_{25}NSO_9$, and sugar, $C_6H_{12}O_6$, an albuminoid substance being formed at the same time. "The acrinyl sulphocyanate (C_7H_7OCNS) is a very active principle, oily, insoluble in water, not volatile. It may be obtained by causing ether to act on the product of the decomposition of sinalbin. Treated by an alkali and then neutralized by an acid, it colors ferric chloride red." (*J. P. C.*, Avril, 1872, 327.)

The analyses of mustard seeds and mustard flour given in the table below, are by Piesse and Stansell. (*Analyst*, 1880, p. 161.)[1]

[1] Analyses of Mustard.

	White Mustard, whole seeds.		White Mustard, ground.		Brown Mustard, whole seeds.	Brown Mustard ground.

According to F. W. Widmayer (*D. C.*, 1904, 8), the oil from yellow seed is of a greenish-yellow color, that of the brown seed a much darker shade. Both have but little odor and a mild, not unpleasant taste. Mustard seed oil is a semi-drying oil. The analytical data showing maximum and minimum results by M. L. Tolman and L. S. Munson on five samples are as follows: Specific gravity at 15.5° C. (59.9° F.), 0.9147 to 0.9193; Butyrorefractometer reading (15.5° C. (59.9° F.)), 74.5 to 76.5; Index of refraction at 15.5° C. (59.9° F.), 1.4750 to 1.4762; Maumené number 61.4 to 79.4; Specific temperature reaction 130.9 to 190.3; Hübl number,

98.4 to 113.0; Saponification value, 173 to 182.8; Melting point of fatty acids, 20.8 to 21.5° C. 69.4°–70.7° F.); Free fatty acids oleic, 0.13 to 1.13 per cent.; Solidification from –8° to –18° C. (17.6° to –0.4° F.). One remarkable feature of this oil is its penetrating or diffusing power. Barrels that will hold olive, cotton seed, or petroleum oil or even new oil or alcohol barrels invariably leak on being filled with it, and it is said by one who has had extensive experience in the mustard business that it has been known to come through a tank which had stood a pressure of 80 pounds of steam. (*D. C.*, 1904, 8.)

J. U. Lloyd has proposed standards for black and white mustard seed, mainly directed towards limiting the proportion of starch; the latter is not a constituent of ripe mustard seed, but commercial mustard nearly always contains starch, due to starch-bearing seeds accidentally present in the mustard seed, or to fraudulent admixture. (*A. J. P.*, 1898, 433.) Dieterich (*Ph. Ztg.*, Oct. 3, 1900, 767) proposed an assay for mustard seed, mustard oil and mustard paper.

Uses.—Mustard seeds swallowed whole operate as a laxative, and have acquired some reputation as a remedy in *dyspepsia*, and in other affections attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful (15.5 Gm.) once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act in some measure by mechanically stimulating the bowels. The powder, commonly called simply mustard, in the quantity of from one to two teaspoonfuls (3.9–7.7 Gm.), is an efficient and prompt—although unpleasant—stimulant emetic, especially valuable in *narcotic poisoning*. As a condiment mustard acts as a stimulant to the gastric mucous membrane, increasing according to Gottlieb (*A. E. P. P.*, 1894, xxxiii, 261), also the pancreatic secretion. By virtue of this stimulant action it will sometimes relieve obstinate *hiccough*.

But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with burning pain, which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal, or double, portion of wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus, may result. This caution is particularly necessary when the patient is insensible and the degree of pain can afford no criterion of the sufficiency of the action. In making a mustard plaster the admixture of alcohol, vinegar, or other fluid than water, should be avoided as hindering the development of the volatile oil. The volatile oil is powerfully rubefacient, and capable of producing speedy vesication, but certainly is less controllable than is the mustard poultice. For external application as a rubefacient, 10 to 20 drops of the oil may be dissolved in a fluidounce of alcohol, or 6 or 8 drops in a fluidrachm of almond or olive oil. (See *Linimentum Sinapis Compositum*, N. F., Part III.) To form a *sinapism* it has been recommended to mix 20 drops of the volatile oil with a gelatinous mass made by heating together 3.5 drachms of glycerin and 5 drachms of starch. Lebaigue proposes applying to one sheet of paper a concentrated solution of *potassium myronate*, and to a second a concentrated solution of *myrosin*, and drying them. When used, the leaves are to be moistened and placed to the surface, one over the other. Volatile oil of mustard is formed by the reaction of the two principles, and a sinapism is obtained. (*J. P. C.*, Août, 1868, p. 118.) The volatile oil of mustard has been given internally in *colic*, two drops being incorporated with a six-ounce mixture, and half a fluidounce (15 mils) given for a dose. In overdoses it is highly poisonous, producing gastro-enteric inflammation, and probably perverting the vital processes by pervading the whole system. Its odor is perceptible in the blood, and is said to impart the smell of horse-radish to the urine. A *spirit of mustard* may be prepared by macerating, for two hours, 250 parts of powdered black mustard with 500 parts of cold water, then adding 120 parts of alcohol of 86 per cent., and distilling over 120 parts of spirit.

Dose, of mustard seed, one to two drachms (3.9–7.7 Gm.).

SODII ACETAS. U. S.

SODIUM ACETATE Sod. Acet.

(sō'dĭ-ī ăˈçę-tăs)

"It contains not less than 59.97 per cent. nor more than 62.96 per cent. of anhydrous sodium acetate, corresponding to not less than 99.5 per cent. of the crystallized salt [$NaC_2H_3O_2 + 3H_2O = 136.07$]. Preserve it in well-closed containers." *U. S.*

Acetate of Soda; Acetas Sodicus (Natricus), Terra Foliata Tartari Crystallisata, Terra Foliata Tartari; Acétate de Soude Cristallisé, *Fr. Cod.*; Natrium Aceticum, *P. G.*; Natriumacetat, Essigsaures Natron, *G.*; Acetato di Sodio, *It.*

Sodium acetate may be easily prepared by adding crystals of sodium carbonate to acetic acid until it is neutralized, filtering, concentrating the solution, and crystallizing. It is prepared in the large way in the manufacture of crude pyroligneous acid, for the purpose of being decomposed, so as to yield the official acetic acid, by the action of sulphuric acid. The steps of the process by which it is made from the crude acid have been given under *Acidum Aceticum*.

Properties.—It is officially described as in "colorless, transparent, monoclinic prisms, or as a granular, crystalline powder; odorless, or having a faint, acetous odor. It has a cooling, saline taste. Efflorescent in warm, dry air. One Gm. of Sodium Acetate dissolves in 0.8 mil of

water and in 19 mils of alcohol at 25° C. (77° F.). An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus or phenolphthalein T.S. When heated to about 58° C. (136.4° F.), the salt begins to liquefy. At about 120° C. (248° F.) it becomes anhydrous; at a higher temperature it is decomposed, with the evolution of inflammable, empyreumatic vapors, leaving a black residue of sodium carbonate and carbon, which imparts to a non-luminous flame an intensely yellow color, shows an alkaline reaction with litmus, and effervesces with acids. Add 0.1 Gm. of the salt to 1 mil of sulphuric acid and 1 mil of alcohol and warm; ethyl acetate is formed, recognizable by its odor. A saturated aqueous solution of the salt is not rendered turbid by the addition of sodium bitartrate T.S. (*potassium*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows not less than 59.97 per cent. nor more than 62.96 per cent. of $NaC_2H_3O_2$.

"Each mil of half-normal sulphuric acid V.S. used corresponds to 0.04101 Gm. of $NaC_2H_3O_2$. Each gramme of Sodium Acetate corresponds to not less than 14.62 mils nor more than 15.35 mils of half-normal sulphuric acid V.S." *U. S.*

Sodium acetate, when crystallized, consists of one acetic acid molecule, one atom of sodium and 3 molecules of water.

Uses.—Sodium acetate is diuretic, acting much like potassium acetate, but is rarely used as a medicine. It is employed principally to yield acetic acid by the action of sulphuric acid. In prescribing this salt, the fact, first noticed by Violette, should not be forgotten, that the mixture of equal parts of it and potassium nitrate, if heated, explodes with great violence. (*N. R.*, April, 1873.)

Dose, twenty grains to two drachms (1.3–7.7 Gm.).

SODII ARSENAS. U. S.

SODIUM ARSENATE Sod. Arsen. [Arsenas sodii, P. I.]

(sō'dĭ-ī ăr'sẹ-năs)

"It contains not less than 58.98 per cent. nor more than 61.92 per cent. of anhydrous sodium arsenate (di-sodium ortho-arsenate), corresponding to not less than 99 per cent. of the crystallized salt [$Na_2HAsO_4 + 7H_2O = 312.08$]. Preserve it in well-closed containers." *U. S.*

Natrum Arsenicum, Arsenias Natricus (Sodicus); Sodium Arseniate; Arseniate of Soda; Arséniate de Soude, *Fr. Cod.*; Natriumarsenat, Arsensaure Natron, *G.*; Arseniato bisodico, *It.*; Arseniato sodico, *Sp.*

In the U. S. P. the crystallized and anhydrous salts are official, while the anhydrous salt is the only one recognized in the Br. authority. The exsiccated salt is to be preferred as the crystallized arsenate is apt to contain varying proportions of water of crystallization. The U. S. P. obviates the consequent uncertainty of dosage by inserting an assay provision.

The process for this salt was first made official by the Br. Pharmacopœia of 1864, and by the U. S. Pharmacopœia of 1870. (See *U. S. D.*, 19th edition, page 1127.) In the process, the arsenious acid (arsenic trioxide) is converted into arsenic acid at the expense of the nitric acid of sodium nitrate, and then combines with the sodium of both salts, carbon dioxide, nitrous fumes being given off. The reaction seems to be as follows:

$$As_2O_3 + 2NaNO_3 + Na_2CO_3 + H_2O = 2Na_2HAsO_4 + N_2O_3 + CO_2$$

According to Higgins, the gases emitted in this process contain more or less arsenic—an inconvenience which may be avoided by first dissolving the arsenious acid in a solution of sodium hydroxide, and then adding the nitrate. The calcination should be performed in a reverberatory furnace. The gases which escape up the chimney are now free from arsenic, and consist only of ammonia and nitrous vapors. (*J. P. C.*, 4e sér., ii, 177.)

Properties.—Sodium arsenate is in "colorless, transparent, monoclinic prisms; odorless. Efflorescent in dry air, and somewhat deliquescent in moist air. *Great caution must be used in tasting it and then only in very dilute solutions.* One Gm. of Sodium Arsenate dissolves in 1.5 mils of water at 25° C. (77° F.); also in about 1 mil of boiling water; slightly soluble in alcohol at 25° C. (77° F.); nearly insoluble in boiling alcohol. When gently heated, the salt loses five molecules of water, and is converted into a white powder. At a higher temperature it loses all of its water of crystallization; when strongly heated, the salt fuses, and at a red heat it is converted into pyroarsenate. Sodium Arsenate responds to the tests for identity and purity prescribed under *Sodii Arsenas Exsiccatus* when taken in proportionate amount.

"**Assay.**—Dissolve about 0.5 Gm. of Sodium Arsenate, accurately weighed, in 25 mils of distilled water, heat the solution to 80° C. (176° F.), and add 10 mils of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand for fifteen minutes at 80° C. (176° F.), then cool and titrate it with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 58.98 per cent. nor more than 61.92 per cent. of Na_2HAsO_4.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each gramme of Sodium Arsenate corresponds to not less than 63.44 mils nor more than 66.59 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

Anhydrous sodium arsenate has the composition Na_2HAsO_4; in crystals it sometimes contains 12 molecules of water, equal to 53.73 per cent. of its weight. According to the official formula, this salt crystallizes with 7 molecules of water, or 40.39 per cent. "The latter salt loses 40.38 per cent. of its weight when dried

at 300° F. (148.9° C.), becoming anhydrous. An aqueous solution of 12.4 grains of anhydrous arsenate of sodium, acidulated with acetic acid, requires not less than 34 grains of acetate of lead for complete precipitation." *Br.* 1885. If the temperature of a solution of the salt be kept at 30° C. (86° F.), crystals will be deposited which contain 4 molecules of water. J. Lefort examined 10 different samples of the salt, obtained from as many different sources, and found their water of crystallization to vary from 44.05 to 57.45 per cent. (*J. P. C.*, 1880, 487.)

Uses.—Sodium arsenate possesses the therapeutic properties of arsenic. (See *Arseni Trioxidum.*) It is usually exhibited in solution. According to H. N. Moyer it is less irritating to the stomach than the more frequently used potassium arsenite. It is also occasionally employed hypodermically.

Pearson's Arsenical Solution, Liquor Sodii Arsenatis Pearson, N. F. (see Part III), is one-tenth the strength of U. S. P. IX *Liquor Sodii Arsenatis,* see page 658. Pearson's solution is used in Europe especially for the purpose of the preparation of arsenical baths in the treatment of *rheumatoid arthritis.*

Dose, of crystallized sodium arsenate, one-twentieth to one-eighth of a grain (0.003–0.008 Gm.).

Off. Prep.—Liquor Sodii Arsenatis (from Dried Salt), *U. S., Br.;* Sodii Arsenas Exsiccatus, *U. S.;* Liquor Sodii Arsenatis Pearson, *N. F.*

SODII ARSENAS EXSICCATUS. U. S. (Br.)

EXSICCATED SODIUM ARSENATE Sod. Arsen. Exsic.

(sō'dĭ-ī ăr'sẹ-năs ĕx-sĭc-cā'tŭs)

"It contains, when dried to constant weight at 150° C. (302° F.), not less than 98 per cent. of Na_2HAsO_4 (185.97). Preserve it in well-closed containers." *U. S.*

Sodii Arsenas Anhydrosus, *Br.*, Anhydrous Sodium Arsenate; Natrium Arsenicum Exsiccatum; Dried (anhydrous) Arsenate of Soda; Arséniate de Soude desséché, *Fr.;* Getrocknetes Natriumarsenate, *G.*

"Sodium Arsenate, in crystals, *a sufficient quantity.* Break the crystals into small fragments, and allow them to effloresce at a temperature between 40° and 50° C. (104° and 122° F.) until they are completely disintegrated; then gradually increase the temperature to 150° C. (302° F.) and continue the drying until the product ceases to lose weight. Reduce it to a fine powder, and transfer it to dry, well-closed containers." *U. S.*

"Anhydrous Sodium Arsenate is obtained by exposing to a temperature of 150° C. (302° F.) crystallised sodium arsenate, which may be prepared by treating with water the product of the fusion of arsenious anhydride with sodium nitrate and sodium carbonate. It contains not less than 98 per cent. of pure anhydrous di-sodium hydrogen arsenate, Na_2HAsO_4." *Br.*

For properties see also *Sodii Arsenas.*

Properties.—It is officially described as "an odorless, amorphous, white powder. It is slightly hygroscopic. *Great caution must be used in tasting it and then only in very dilute solutions.* One Gm. of Exsiccated Sodium Arsenate dissolves in 3.1 mils of water at 25° C. (77° F.); also in about 1.3 mils of boiling water; slightly soluble in alcohol at 25° C. (77° F.); nearly insoluble in boiling alcohol. Its aqueous solution (1 in 20) is alkaline to litmus. It imparts an intensely yellow color to a non-luminous flame. An aqueous solution of the salt (1 in 20) yields a white precipitate with barium chloride T.S., and a dark red precipitate with silver nitrate T.S.; both of these precipitates are soluble in nitric acid. Add 5 mils of tenth-normal silver nitrate V.S. to 2 mils of an aqueous solution of the salt (1 in 20) and redissolve the precipitate with the aid of a slight excess of ammonia water; no black precipitate of reduced silver appears on boiling for one minute (*arsenite*). Add 1 mil of ammonium sulphide T.S. to 5 mils of an aqueous solution of the salt (1 in 100); no dark coloration appears (*lead, copper, or iron*)." *U. S.*

"A white powder. Soluble in 6 parts of *water;* slightly soluble in *alcohol* (90 per cent.). Aqueous solution alkaline to *litmus.* Yields the *reactions* characteristic of sodium and of arsenates. When 0.25 gramme is dissolved in 25 millilitres of *water,* and to the solution 3 grammes of *potassium iodide* and 25 millilitres of *hydrochloric acid* are added, not less than 26.3 millilitres of *N/10 solution of sodium thiosulphate* are required to decolorise the iodine liberated. Yields no characteristic *reactions* for lead, copper, iron, aluminium, calcium, carbonates, chlorides, nitrates, or sulphates. Loses not more than 2 per cent. of its weight when dried at 150° C. (302° F.) (limit of moisture)." *Br.*

"**Assay.**—Dissolve about 0.3 Gm. of Exsiccated Sodium Arsenate, dried to constant weight at 150° C. (302° F.) and accurately weighed, in 25 mils of distilled water, in a glass-stoppered bottle, heat the solution to 80° C. (176° F.) and add 10 mils of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand in the stoppered bottle for fifteen minutes at 80° C. (176° F.), then cool and titrate it with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows, in the dried salt, not less than 98 per cent. of Na_2HAsO_4.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each gramme of Exsiccated Sodium Arsenate, previously dried, corresponds to not less than 105.4 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

Uses.—Dried or exsiccated sodium arsenate is useful when it is desired to exhibit the salt in pill form, but differs in no way in its physiological action from sodium arsenate.

Dose, one-fortieth to one-fifteenth of a grain (0.0016–0.004 Gm.).

SODII BENZOAS. U. S., Br.

SODIUM BENZOATE Sod. Benz.

(sō'dĭ-ī bĕn'zō-ās)

"It contains, when dried to constant weight at 110° C. (230° F.), not less than 99 per cent. of $NaC_7H_5O_2$ (144.04). Preserve it in well-closed containers." *U. S.* "Sodium Benzoate may be obtained by neutralizing benzoic acid with sodium carbonate. It contains not less than 96 per cent. of pure sodium benzoate, $NaC_7H_5O_2$." *Br.*

Sodæ Benzoas; Benzoate of Soda; Benzoate de Soude, *Fr. Cod.;* Natrium Benzoicum, Natriumbenzoat, Benzoesaures Natron, *G.;* Benzoato di sodio, *It.;* Benzoato sodico, *Sp.*

Sodium benzoate is easily made by adding benzoic acid to a concentrated hot solution of sodium carbonate or bicarbonate until effervesence ceases, and allowing the solution to cool and crystallize. R. Rother, in order to avoid annoyances in the effervescence mixes four ounces of benzoic acid and two and three-fourths ounces of sodium bicarbonate in an evaporating dish with from two to four fluidounces of alcohol; when a uniform mixture is produced, from three to six fluidounces of water are added, heat applied gently, and the powder granulated.

Properties.—It is officially described as "a white, amorphous, granular or crystalline powder; odorless, and having a sweetish taste. It is permanent in the air. One Gm. of Sodium Benzoate dissolves in 1.8 mils of water and in 61 mils of alcohol at 25° C. (77° F.), also in 1.4 mils of boiling water. An aqueous solution of Sodium Benzoate (1 in 20) is neutral or slightly alkaline to litmus. When heated, the salt melts, emits vapors having the odor of benzoic acid, then chars, and finally leaves a residue of sodium carbonate and carbon. To a non-luminous flame it imparts an intensely yellow color. Add a few drops of ferric chloride T.S. to an aqueous solution of the salt (1 in 20); a flesh-colored precipitate is deposited. Diluted hydrochloric or sulphuric acid produces in a concentrated aqueous solution of the salt a voluminous white precipitate of benzoic acid. Acidulate 10 mils of an aqueous solution of the salt (1 in 50) with hydrochloric acid and filter; the filtrate does not respond to the Test for heavy metals (see Part III, Test No. 3)." *U. S.*

"A white subcrystalline, or amorphous powder. Inodorous, or with a faint odor of benzoin; taste unpleasant, sweetish, saline. Soluble in 2 parts of *water,* and in 24 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium. An aqueous solution (1 in 10) is slightly alkaline to *litmus,* gives a pale reddish precipitate with *T. Sol.* of *ferric chloride,* and yields with *diluted hydrochloric acid* a crystalline precipitate of benzoic acid. Loses not more than 4 per cent. of its weight when dried at 110° C. (230° F.). 1 gramme of this dried salt heated to redness till gases cease to be evolved leaves an alkaline residue which, treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 13.7 or more than 13.9 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, iron, potassium, or carbonates, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million." *Br.*

"**Assay.**—Dry the salt to constant weight at 110° C. (230° F.) and proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows, in the dried salt, not less than 99 per cent. of $NaC_7H_5O_2$.

"Each mil of half-normal sulphuric acid V.S. used corresponds to 0.07202 Gm. of $NaC_7H_5O_2$. Each gramme of Sodium Benzoate, previously dried, corresponds to not less than 13.75 mils of half-normal sulphuric acid V.S." *U. S.*

Elias Elvove (*A. J. P.,* 1912, p. 298) proposes a new method for the assay of sodium benzoate and for all salts of potassium, sodium, and lithium with organic acids. It is based upon the decomposition of the salt with an excess of normal sulphuric acid and the subsequent cautious ignition to destroy organic matter and eliminate excess of sulphuric acid, leaving as a residue a normal sulphate of the basic element from the weight of which the purity of the original compound may be calculated.

Uses.—Sodium benzoate is used in the treatment of *rheumatism,* either of the acute or chronic type. Its mode of action in these conditions is apparently similar to that of the salicylates, although it is usually a less efficacious remedy. It has also been used in the treatment of *lithemia* and *gouty conditions* but with less convincing benefit. It is of service also as a urinary antiseptic, but the ammonium salt is generally preferred. Although benzoic acid is a powerful germicide the neutral salts are only feebly so. According to Doepner a 1 per cent solution of sodium benzoate has only a slight retarding influence upon the growth of the bacteria; on the other hand, Herter (*J. A. M. A.* 1910, liv) states that one-fifth of one per cent. has a perceptible inhibiting action. It is probable that the strong effects of sodium benzoate as a food preservative are due to a partial liberation of benzoic acid by the acidulous matters of the food stuff to which it is added. It is quite certain that an acid condition of the urine very greatly increases its efficacy as a urinary antiseptic.

Dose, from fifteen to thirty grains (1.0–2.0 Gm.).

Off. Prep.—Liquor Antisepticus, *N. F.;* Liquor Antisepticus Alkalinus, *N. F.;* Sodii Boro-Benzoas, *N. F.*

SODII BENZOSULPHINIDUM. U. S.

SODIUM BENZOSULPHINIDE Sod. Benzosulphin. [Sodium-Saccharin, Soluble Saccharin]

(sō'dĭ-ī bĕn-zō-sŭl-phĭ-nĭ'dŭm)

"The sodium salt [$NaC_7H_4O_3NS+2H_2O$= 241.14] of benzosulphinide. Preserve it in well-closed containers." *U. S.*

This salt may be prepared by the careful neutralization of sodium carbonate solution with benzosulphinide or so-called insoluble saccharin, and the subsequent concentration of the solution and crystallization of the salt. "Sodium Benzosulphinide occurs in colorless, rhombic prisms or as a white, crystalline powder; odorless or having a faint aromatic odor and an intensely sweet taste, even in dilute solutions; somewhat efflorescent. One Gm. of Sodium Benzosulphinide dissolves in 1.2 mils of water, and in about 50 mils of alcohol at 25° C. (77° F.). An aqueous solution of the salt (1 in 10) is neutral or only slightly alkaline to litmus, but produces no red color with phenolphthalein T.S. On incineration the salt leaves a residue consisting chiefly of sodium sulphate. Mix 10 mils of an aqueous solution of the salt (1 in 10) with 1 mil of hydrochloric acid; a crystalline precipitate of benzosulphinide is produced. Add a few drops of ferric chloride T.S. to 10 mils of an aqueous solution of the salt (1 in 20) previously acidulated with from 3 to 5 drops of acetic acid; no pink or violet precipitate is produced (*benzoate or salicylate*). In other respects it responds to the tests for identity and purity under *Benzosulphinidum*, omitting the melting point and the tests for ash, benzoic acid or salicylic acid." *U. S.*

Uses. — Sodium benzosulphinide is useful solely as a sweetening agent in those conditions, such as *diabetes, gout, obesity,* etc., in which sugar is objectionable. It has the advantage over the anhydride (see *Benzosulphinidum*) of being more freely soluble.

Dose, one-fourth to three grains (0.016–0.2 Gm.).

SODII BICARBONAS. U. S., Br.

SODIUM BICARBONATE Sod. Bicarb.

(sō'dĭ-ī bī-cär'bo-nās)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of $NaHCO_3$ (84.01). Preserve it in well-closed containers, in a cool place." *U. S.* "Sodium Bicarbonate may be obtained by exposing crystals of sodium carbonate to carbon dioxide, or by the interaction of sodium chloride and ammonium bicarbonate. It contains not less than 98.5 per cent. of pure sodium hydrogen carbonate, $NaHCO_3$." *Br.*

Natrium Carbonicum Acidulum; Bicarbonas Sodicus; Bicarbonate of Soda, Soda Saleratus, Acid Sodium Carbonate; Sodium Hydrogen Carbonate; Carbonate (Bi) de Soude, *Fr. Cod.;* Sel de Vichy, *Fr.;* Natrium Bicarbonicum, *P. G.;* Natriumbicarbonat, Doppeltkohlensaures Natron, *G.;* Bicarbonato di sodio, *It.;* Bicarbonato sodico, *Sp.*

Two kinds of sodium bicarbonate were formerly official—one, which is known by the title of this article, and which, to comply with the tests, must not have more than one per cent. of impurity, and the other, "commercial bicarbonate," which must contain at least 95 per cent. of pure bicarbonate. Formerly to obtain a salt which would comply with the official test it was necessary to purify the commercial salt, and the process of the U. S. Pharm. 1870 will be found as serviceable as any to accomplish this purpose. The U. S. Pharm. 1890 recognized only the purer salt, having dismissed *Sodii Bicarbonas Venalis.* Sodium bicarbonate must now contain 99 per cent. of the pure salt, and the quality of the commercial salt has greatly improved in late years.

Immense quantities of sodium bicarbonate were formerly imported from Great Britain, but the importation has ceased because of the development of the industry in this country. It is now made of excellent quality by the Pennsylvania Salt Manufacturing Co., at Natrona, Pa., using cryolite as raw material; and by the Solvay Process Co., of Geddes, near Syracuse, N. Y., using the ammonia-soda process; and the Michigan Alkali Co., of Wyandotte, Mich., and the Mathison Alkali Co., of Saltville, Va., from brine.

In the United States Pharmacopœia of 1860 a process for making sodium bicarbonate was given but it has since been abandoned, as the salt can be made much more economically on the large scale. The process consists in treating crystallized sodium carbonate, contained in suitable chambers, with carbon dioxide gas until the carbonate has taken up another molecule of carbon dioxide. It is formed by the union of neutral carbonate, Na_2CO_3, with carbon dioxide gas, CO_2, in the presence of water, H_2O, according to the following reaction:

$$Na_2CO_3 + CO_2 + H_2O = 2HNaCO_3$$

two molecules of the bicarbonate being generated. The necessary water is obtained through the liberation of the water of crystallization of the carbonate; in fact, provision has to be made for the escape of the excess by placing the crystals upon perforated bottoms.

Properties.—"Sodium Bicarbonate is a white, opaque powder; odorless, and having a cooling, mildly alkaline taste. It is permanent in dry air, but slowly decomposed in moist air. One Gm. of Sodium Bicarbonate dissolves in 10 mils of water at 25° C. (77° F.); insoluble in alcohol. An aqueous solution of Sodium Bicarbonate (1 in 20) when freshly prepared with cold distilled water, without shaking, is slightly alkaline to litmus. The alkalinity increases by standing, agitation, or increase in temperature. When heated above 15° C. (59° F.), an aqueous solution of the salt gradually loses carbon dioxide, and at boiling temperature the salt is entirely converted into normal sodium carbonate. When heated, the salt is decomposed into normal sodium carbonate, water, and carbon dioxide, and at 100° C. (212° F.) the loss is about 36.5 per cent. of its weight. At a bright red heat the residue fuses. To a non-luminous flame it imparts an intensely yellow color. An aqueous solution of the salt effervesces strongly with acids. No odor of ammonia is evolved on heating Sodium Bicarbonate in a test tube. Dissolve 1 Gm. of the salt in 20 mils of distilled water at 25° C. (77° F.); it yields a clear and colorless solution, leaving no residue. Dissolve 1 Gm. of the salt without agitation in 20 mils

of distilled water at a temperature not exceeding 15° C. (59° F.) and add 0.2 mil of normal hydrochloric acid and 2 drops of phenolphthalein T.S.; a red tint does not appear immediately (*carbonate*). An aqueous solution of the salt (1 in 50), mixed with a slight excess of hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3).

Assay.—Mix about 3 Gm. of Sodium Bicarbonate, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, with 25 mils of distilled water and titrate with normal sulphuric acid V.S., methyl orange T.S. being used as indicator. It shows, in the dried salt, not less than 99 per cent. of $NaHCO_3$.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.08401 Gm. of $NaHCO_3$. Each gramme of Sodium Bicarbonate, previously dried, corresponds to not less than 11.78 mils of normal sulphuric acid V.S." *U. S.* "A white powder, or small, opaque, monoclinic crystals. Taste saline. Soluble in 11 parts of *water*. Yields the *reactions* characteristic of sodium and of bicarbonates. 1 gramme requires for neutralization not less than 11.7 or more than 11.9 millilitres of *N/1 solution of sulphuric acid*. Yields no characteristic *reactions* for copper, iron, aluminium, calcium, sulphites, or thiosulphates, and not more than the slightest *reactions* for chlorides, sulphates, or ammonium. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million. When 1 gramme of Sodium Bicarbonate is dissolved in 20 millilitres of cold *water*, without shaking, and 0.2 millilitre of *N/1 solution of sulphuric acid* and 2 drops of *solution of phenolphthalein* are added, no red color is immediately developed (limit of carbonate). The addition of *T. Sol. of ferric chloride* to the aqueous solution acidified with *hydrochloric acid* causes no red coloration (absence of thiocyanates).

"20 grammes of Sodium Bicarbonate are neutralized by 16.7 grammes of Citric Acid, and by 17.8 grammes of Tartaric Acid." *Br.*

The salt furnished by the manufacturers almost always comes up to the requirements of the Pharmacopœias. The presence of carbonate may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with magnesium sulphate, and by a solution in 40 parts of water affording, without agitation, an orange-colored or reddish-brown precipitate with corrosive sublimate. E. Kuhlmann recommends rosolic acid as the best test for detecting monocarbonate; if a small fragment be placed in a solution of sodium bicarbonate, the liquid remains perfectly colorless even after a quarter of an hour if the salt be pure; but if it contain from one to four per cent. of monocarbonate a rose-red color will be produced after a few moments, and *immediately* in the presence of larger quantities, rapidly changing them to purple-red. (*A. Pharm.*, 1887, p. 72.)

When the solution is exposed to heat, the salt gradually parts with carbon dioxide, and, at the temperature of 100° C. (212° F.), is converted into sesquicarbonate, $Na_2CO_3.NaHCO_3.2H_2O$. At red heat the second equivalent of carbon dioxide is expelled, and the anhydrous carbonate is left.

Sodium thiosulphate has been detected in small amount in European sodium bicarbonate by E. Mylius, who supersaturated the suspected bicarbonate in solution with sulphuric acid, and added a little pure zinc, when the odor of hydrogen sulphide was produced. A slight trace of arsenic was also discovered in the sodium bicarbonate. (*A. Pharm.*, 1886, p. 598.) F. B. Power subsequently examined samples of American bicarbonate, and found them all free from thiosulphate and arsenic; he detected, however, traces of chlorides, ammonia, and monocarbonate in the commercial salt. (*Ph. Rund.*, 1887, p. 35.)

Uses.—Sodium bicarbonate is used in medicine solely for the purpose of overcoming hyperacidity either of the stomach, blood, or urine. In cases of gastric conditions attended with increased acidity, whether due to fermentation or oversecretion in the acid glands, it is one of the most useful remedies we possess. It has the advantage over the carbonates of being more palatable and less irritant to the gastric mucosa. In cases of diminished alkalinity of the general system the so-called *acidosis*, such as is seen in *diabetic coma*, the intravenous injection of large doses of bicarbonate of soda offers greater hope of relief than any other mode of treatment. For this purpose large doses are required; Labbé and Carrié (*Rev. Internat. de Med.*, 1911, p. 250) administered daily for several days 15 grammes intravenously and 20 grammes by the mouth in a case of diabetic coma. For the purpose of diminishing excessive acidity of the urine, as in *rheumatic* or *gouty conditions*, while the drug is frequently employed it has no advantage over the citrate and is more liable to disturb digestion.

In pharmacy it is widely employed for making effervescent powders.

Dose, for an adult, from ten grains to a drachm (0.65–3.9 Gm.), taken most conveniently in a glass of carbonic acid water.

Off. Prep.—Trochisci Sodii Bicarbonatis, *U. S.* (*Br.*); Liquor Sodæ et Menthæ, *N. F.*

SODII BORAS. U. S. (Br.)

SODIUM BORATE Sod. Bor. [Borax, Sodium Tetraborate, Sodium Pyroborate]

(sō'dĭ-ī bō'răs)

"It contains not less than 52.32 per cent. nor more than 54.92 per cent. of anhydrous sodium borate (sodium biborate or tetraborate), corresponding to not less than 99 per cent. of the crystallized salt [$Na_2B_4O_7 + 10H_2O = 382.16$]. Preserve it in well-closed containers." *U. S.* "Purified Borax may be obtained from native borax; it may also be obtained by boiling native calcium borate with solution of sodium carbonate, and contains not less than 98.9 per

cent. of sodium pyroborate, $Na_2B_4O_7,10H_2O$." *Br.*

Borax Purificatus, *Br., P. G.*; Purified Borax; Sodæ Biboras, Biborate of Sodium; Sodium Biborate, Natrium Biboricum (Biboracicum), Boras Sodicus; Borate de Soude, *Fr. Cod.*; Borax, Bauracon, Sel de Perse, *Fr.*; Borax, Borsaures Natron, *G.*; Borato di sodio, Borace, *It.*; Borato sodico, Borax, *Sp.*

Borax was known to the ancients; but its chemical character was first ascertained by Geoffroy in 1732. It exists in nature, and may be obtained by artificial means. It occurs in several localities in Europe, in Peru, and in beds, associated with calcium borate, in the district of Iquique, in the republic of Ecuador. This mineral (*boronatrocalcite*), which has become an article of commerce, and is considerably used as a substitute for borax, contains, according to T. L. Phipson, 34 per cent. of water, 11.95 of soda, 14.45 of lime, 34.71 of boric acid, 1.34 of chlorine, 1.10 of sulphuric acid, 0.60 of silica, and 2 of sand, and may be considered as a compound essentially of one molecule of crystallized sodium borate and two molecules of calcium borate, with two molecules of water. It is said also to contain usually some iodine and bromine. (G. Sims.) Borax has long been known to occur in certain lakes of Thibet and Persia, from which it was obtained by spontaneous evaporation. It constituted the impure borax called in commerce *tincal*.

Several sources of borax have been developed within the limits of the United States. The existence of a borax lake in California was first made known by J. A. Veatch, who visited it in September, 1856, and, upon examining its waters, found borax among its constituents. The borax lake is a small offset of a large sheet of water, called Clear Lake, which is situated in the midst of a volcanic region, about 36 miles from the Pacific, and about 100 miles north of San Francisco. This lake supplied large quantities of borax to commerce, but in 1868 operations practically ceased at Borax Lake. More recently attention has been attracted to Searles Lake, in San Bernardino County, where potash salts occur with the borax and soda salts. This is now being worked for both potash and borax by concentration and fractional crystallization.

At present the chief supply of American borax comes from the more easily worked deposits in the sandy deserts about Death Valley, southeast of Pyramid Lake, in Nevada, in the Slate Range district, San Bernardino Co., and the Saline Valley, Inyo Co., California. In order to reduce as much as possible the cost of transportation before the present railway facilities, the boraxes of the Pacific coast were made usually of high quality, and the so-called "*boracic acid glass*," one pound of which is equal to three pounds of ordinary borax, was prepared. For an interesting description of the Slate Range district, see *Chem News*, 1886, 245. The most important deposits which are worked in California are the *colemanite* (*calcium borate*) deposits twelve miles northeast of Daggett, in the Mojave Desert. The formation (one hundred feet or more in width) has been traced for fully ten miles. The colemanite is readily dissolved by sodium carbonate solution, when the borax crystallizes out.

The production of borate in California for 1915 amounted to 67,004 tons. Only two other countries supply any considerable amount of borate minerals: Chili, which, in 1912, produced 43,356 tons of calcium borate, and Italy, which, in 1912, produced 2309 tons of crude boric acid.

Preparation.—Borax is made for the European market by the direct combination of *native boric acid* with soda. The acid is found abundantly in the crater of Vulcano, one of the Lipari Islands, but principally in a volcanic region of Tuscany occupying a space of ten or twelve miles. Within this region are found numerous hillocks and fissures, the latter of which emit hot aqueous vapor containing boric acid and certain gases. Around one or several of these fissures a circular basin of masonry is built, which is filled with water and called a lagoon. By the jets of vapor constantly breaking through it, the water becomes gradually impregnated with boric acid and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is allowed to rest and deposit mechanical impurities. From this reservoir the solution is made to pass into leaden evaporating pans, heated by the natural vapor, where it receives sufficient concentration to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid, thus obtained contains, on an average, 84 per cent. of boric acid, the impurities consiting chiefly of alum, the double ammonium and magnesium sulphate, and calcium sulphate. The seven works in the neighborhood of Castelnuovo in Tuscany, belonging to Count Larderel, were producing, in 1878, over three millions of kilogrammes. Vulcano yielded 4000 kilogrammes of boric acid yearly. The crude acid is converted into borax by dissolving it to saturation in a solution of sodium carbonate, heated by steam, and the liquor, after boiling, is allowed to stand for ten or twelve hours. It is then drawn off into wooden vessels lined with lead, where it crystallizes. The impure crystals thus obtained are refined by dissolving in water heated by steam, adding sodium carbonate to the solution, and crystallizing. The merit of introducing the process for obtaining artificial borax belongs to Cartier and Payen, who succeeded in establishing its manufacture in France. According to Veatch, boric acid exists in the sea water on the coast of California.

Another method of neutralizing the Italian boric acid is practised in England. Instead of combining the acid and alkali in solution, the manufacturer mixes the acid in a solid state with a proper proportion of soda ash, and exposes the mixture to the heat of a reverberatory furnace, provision being made for the collection of a large quantity of ammonia, which is always present in the crude acid and escapes during the process. The remaining operations are similar to those performed in the prepara-

tion of sodium carbonate from the cake. (*A. J. P.*, 1867, p. 339.)

Properties.—Borax is a white salt, occurring in "colorless, transparent, monoclinic prisms, or as a white powder; odorless, and having a sweetish, alkaline taste. It is slightly efflorescent in warm dry air. One Gm. of Sodium Borate dissolves in 15 mils of water, and in about 1 mil of glycerin at 25° C. (77° F.); also in 0.6 mil of boiling water; insoluble in alcohol. An aqueous solution of the salt (1 in 20) is alkaline to litmus and turns turmeric paper reddish-brown. If the solution has been acidulated with hydrochloric acid, turmeric paper remains unchanged at first, but on drying becomes brownish-red, and this color is temporarily changed to greenish-black by moistening with ammonia water. When heated, the salt at first loses part of its water of crystallization, then melts, and, when further heated, swells and forms a white porous mass. At a red heat it loses all of its water of crystallization and fuses to a colorless glassy mass. To a non-luminous flame it imparts an intensely yellow color. Form a bead of borax on a platinum wire, dip it in glycerin, and hold it in a non-luminous flame; a transient, bright green color appears. An aqueous solution of the salt (1 in 20) does not effervesce with acids (*carbonate or bicarbonate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Dissolve about 5 Gm. of Sodium Borate, accurately weighed, in 100 mils of distilled water and titrate the solution with normal hydrochloric acid V.S., methyl orange T.S. being used as indicator. It shows not less than 52.32 per cent. nor more than 54.92 per cent. of $Na_2B_4O_7$.

"Each mil of normal hydrochloric acid V.S. used corresponds to 0.1010 Gm. of $Na_2B_4O_7$. Each gramme of Sodium Borate corresponds to not less than 5.18 mils nor more than 5.44 mils of normal hydrochloric acid V.S." *U. S.*

"Transparent colorless crystals, sometimes slightly effloresced, with a weak alkaline reaction. Taste saline, alkaline. Soluble in 25 parts of *water*, and in 1 part of *glycerin;* insoluble in *alcohol* (90 per cent.). Colors flame intensely yellow. Its aqueous solution, acidified with *hydrochloric acid,* turns *turmeric paper* brown. A hot saturated solution, acidfied with a mineral acid, deposits, as it cools, crystals of boric acid, the solution of which in *alcohol* (90 per cent.) burns with a green flame. 2 grammes dissolved in *water* require for neutralisation 10.4 millilitres of *N/1 solution of sulphuric acid, solution of methyl-orange* being used as indicator; and if to this neutralised solution an equal volume of *glycerin* is added, 20.8 millilitres of *N/1 solution of sodium hydroxide* are required for neutralisation, *solution of phenolphthalein* being used as indicator. Yields no characteristic *reactions* for copper, iron, or calcium, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Above a red heat it melts into a limpid liquid, which, after cooling, concretes into a transparent solid, called *glass of borax,* much used as a flux in assays with the blowpipe. Borax has been found in the English market adulterated to the extent of 20 per cent. with sodium phosphate. This may be detected by exposing the suspected borax to the heat of a drying-room for a few hours, when the phosphate, if present, will effloresce, and may be picked out. Commercial borax is used as a flux in metallurgical operations; as the basis of the enamel so much applied to iron utensils, glazed brick, and much china, earthenware, and tiling; in the laundry with starch to impart a gloss to linen; by the meat packers of the United States (1000 tons yearly) as an antiseptic for meat intended for export to countries whose laws permit its presence, and very largely in soaps and toilet preparations and in detergent powders.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it called *soluble cream of tartar,* which is sometimes used in medicine. This preparation attracts moisture from the air, and is soluble in its own weight of cold and half its weight of boiling water. (See *Potassii Bitartras.*) R. F. Fairthorne states that borax is more soluble in water if sugar has been added to it. (*A. J. P.*, March, 1881.) Soluble cream of tartar may be made by substituting boric acid for the borax. *Boric acid soluble cream of tartar* was directed by the French Codex of 1837, and was made by the following formula. Four hundred parts of cream of tartar and 100 of the acid are dissolved in a silver basin, at the boiling temperature, in 2400 parts of water. The solution is kept boiling until the greater part of the water is consumed. The fire is then moderated, and the solution continually stirred while the evaporation proceeds. When the matter has become very thick, it is removed by portions, which are flattened in the hand, completely dried by the heat of a stove, powdered, and kept in well-stoppered bottles. This form of soluble cream of tartar is more soluble than that made with borax. According to E. Robiquet, in order to obtain soluble cream of tartar, made with boric acid, of good quality, it is necessary to use a large quantity of water, and to boil for a long time. By proceeding thus, the boric acid undergoes a molecular modification, equivalent to a change from the crystallized to the vitreous condition, and a preparation readily and totally soluble in cold water is insured. The product should not be powdered, but kept in large grains. (*J. P. C.*, xxi, 197.) Borax is incompatible with the salts of the alkaloids; in warm solution it decomposes hydrated chloral.

Composition.—Borax has the formula $Na_2B_4O_7 + 10H_2O$. It ordinarily crystallizes in monoclinic prisms, and contains ten molecules of water (*prismatic borax*); but a variety of the salt exists which crystallizes in octahedrons, and contains only five molecules of water (*octahedral borax*). The latter is obtained in the artificial production of borax by crystallizing from a

concentrated solution at a temperature between 60° and 80° C. (140° and 176° F.). When a solution of borax is evaporated at 100° C. (212° F.), the salt is left as a transparent, amorphous, brittle mass, containing four molecules of water. (Schweitzer.) Borax is looked upon as having the following probable composition, $2NaBO_2$. $B_2O_3.10H_2O$.

Sodium borate (neutral).—A soluble borate may be made by adding boric acid to a hot concentrated aqueous solution of sodium biborate or borax until it has a neutral reaction; crystals separate which have been erroneously described under the name sodium tetraborate. They are transparent, fragile, and glassy; it is found in commerce in glass-like masses. It is soluble in cold water, but more soluble (70 per cent.) in hot water. It is probably a mixture and not a true compound. Sodium metaborate, $NaBO_2H_2O$, is also known as neutral sodium borate and several compounds of this salt with free metaboric acid, HBO_2, are also known but are little used.

Boric acid may be obtained artificially by decomposing a hot saturated solution of borax with sulphuric acid, which unites with the soda to form sodium sulphate and sets free the acid. As thus obtained it is in white, shining, scaly crystals, characterized by the property of imparting a light-green color to the flame of burning alcohol. Boric acid has the formula H_3BO_3, and is now official. (See *Acidum Boricum.*) *Boron* is a non-metallic element, which, like carbon, is found to exist in two allotropic states, designated amorphous, and crystallized boron, corresponding severally to amorphous carbon and to the diamond. Crystallized boron is very brilliant, and of different colors, from garnet-red to a nearly colorless honey-yellow. Its density is 2.68, and its hardness very great, approximating that of the diamond. Amorphous borax of a density almost equal to that of the crystalline variety has been obtained and is now used because of its high resistance to the electric current.

Uses.—The action of borax and of boric acid upon the animal system are identical. The effects of borax are, however, very feeble, Cyon having found that in daily doses of three drachms borax exerts no perceptible influence upon the dog. Nevertheless, in sufficient amount it exerts a depressing influence upon the heart as well as upon the spinal centers, and a number of instances of poisoning from it have been reported. The symptoms have varied somewhat, but in most if not all the cases there have been great depression of spirits, fall of bodily temperature, a very feeble pulse—rapid or slow—and an erythematous eruption accompanied with much swelling of the parts, and especially affecting the lower extremities, and followed by exfoliation; nausea, violent vomiting, and hiccough have been present in some cases; ecchymoses have been noted; the mind usually remains clear until late in the poisoning, but death has been preceded by coma, with disturbances of the respiration, and involuntary discharges. The continued use of borax has produced "*borism*," which is characterized by gastric irritation, a peculiar absence of fatty matter and of moisture from the skin, and various skin eruptions, especially eczema, reddish papules with squamous desquamating borders, seborrheic acne, and scarlatiniform plaques.

The only systemic purpose for which borax is at present employed is in the treatment of *epilepsy*, but in a careful test made on a large scale in the epileptic ward of the Philadelphia Hospital, by H. C. Wood many years ago, it was found to have little or no influence upon that disorder, and these unfavorable conclusions have been confirmed by Yoedicke (*Med. Klin.*, 1912, p. 2020), who found that only a small percentage of cases seemed to be benefited by it.

Borax even in saturated solution is not at all germicidal, but it does possess slight antiseptic properties. According to Miquel the antiseptic strength is 1 in 14, which would be approximately a saturated solution at ordinary temperatures. It is widely employed as an antiseptic wash for *ulcers* and *abscesses*, but especially for inflammatory conditions of the mucous membranes, such as *conjunctivitis*, *stomatitis*, *cystitis*, *vaginitis*, and the like. It is probable that its beneficial action in these conditions is due more to its innocuousness than to its antibacterial powers. Because of its alkalinity it is a valuable detergent, especially for cleansing mucous membranes. It is also of service as a urinary antiseptic for administration by the mouth, especially when the urine is too highly acid; being eliminated unchanged it tends to alkalinize the urine.

Dose, ten to twenty grains (0.65–1.3 Gm.).

SODII BROMIDUM. U. S., Br.

SODIUM BROMIDE Sod. Brom.

(sō′dĭ-ĭ brō′mĭ-dŭm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 98.5 per cent. of NaBr (102.92). Preserve it in well-closed containers." *U. S.* "Sodium Bromide may be obtained in the same manner as Potassium Bromide, sodium carbonate being used in place of potassium carbonate. When dried at 110° C. (230° F.) it contains not less than 99 per cent. of pure sodium bromide, NaBr." *Br.*

Bromure de Sodium, *Fr. Cod.;* Natrium bromatum, *P. G.;* Natriumbromid, Bromnatrium, *G.;* Bromuro di sodio, *It.;* Bromuro sodico, *Sp.*

This salt contains a larger proportion of bromine than does potassium bromide, on account of the lower atomic weight of sodium, sodium bromide containing about 77 per cent. of bromine, while potassium bromide contains about 10 per cent less. It is a trifle more soluble in water and alcohol. It may be made by the

same process that is employed for potassium bromide, substituting sodium carbonate for potassium carbonate. According to Castelhaz, it is best made by transforming bromine into ammonium bromide, separating any iodine present as iodide by crystallization from the mother waters, and decomposing the ammonium bromide with sodium carbonate. The solution should be evaporated by heating carefully. (*A. J. P.*, xlii, 509.)

Properties.—It occurs in "colorless or white, cubical crystals, or as a white, granular powder; odorless, and having a saline taste. The salt absorbs moisture from the air without deliquescing. One Gm. of Sodium Bromide dissolves in 1.1 mils of water and in 16 mils of alcohol at 25° C. (77° F.). An aqueous solution of the salt (1 in 20) is neutral or faintly alkaline to litmus. When heated to a bright red heat, the salt fuses without decomposition, and at a somewhat higher temperature it volatilizes. To a nonluminous flame it imparts an intensely yellow color. Silver nitrate T.S., added to an aqueous solution of the salt (1 in 10), produces a yellowish-white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water. Dissolve 1 Gm. of the salt in 10 mils of distilled water and add 0.1 mil of tenth-normal sulphuric acid V.S.; no color is produced by the subsequent addition of a drop of phenolphthalein T.S., even after boiling (*alkali*). Add a few drops of ferric chloride T.S. and 1 mil of chloroform to 10 mils of an aqueous solution of the salt (1 in 20), and shake the mixture; the chloroform does not acquire a violet tint (*iodide*). Drop 1 mil of diluted sulphuric acid on about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). Ten mils of an aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, is not rendered turbid by the addition of 1 mil of potassium sulphate T.S. (*barium*); another 10 mil portion, acidulated with hydrochloric acid, is not rendered more than slightly turbid by barium chloride T.S. (*sulphate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Proceed as directed under the Assay for bromides (see Part III, Test No. 5), using about 0.4 Gm. of Sodium Bromide, dried to constant weight at 100° C. (212° F.), and accurately weighed. It shows, in the dried salt, not less than 98.5 per cent. of NaBr.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.010292 Gm. of NaBr. Each gramme of Sodium Bromide, previously dried, corresponds to not less than 95.7 mils nor more than 98.3 mils of tenth-normal silver nitrate V.S." *U. S.*

"Small, white, cubic crystals, or a white granular powder, somewhat deliquescent. Taste saline, somewhat bitter. Soluble in 1.5 parts of *water*, and in 16 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium and of bromides. Loses not more than 5 per cent. of its weight when dried at 110° C. (230° F.). 0.5 gramme of this dried salt, dissolved in *water*, requires for complete precipitation not less than 48.1 or more than 48.9 millilitres of *N/10 solution of silver nitrate*. Yields no characteristic *reactions* for copper, iron, aluminium, zinc, calcium, magnesium, potassium, ammonium, carbonates, cyanides, bromates, or iodates, and not more than the slightest *reactions* for chlorides, iodides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—The physiological and therapeutic properties of sodium bromide are precisely similar to those of potassium bromide. (See page 890.) Because of the depressant effects of potassium on the heart when injected into the blood stream some believe that sodium bromide is preferable in cases of circulatory weakness. It appears to be somewhat less prone to disturb the stomach than the potassium salt and is usually to be preferred.

Dose, ten to sixty grains (0.65–3.9 Gm.).

Off. Prep.—Elixir Sodii Bromidi, *N. F.*; Elixir Trium Bromidorum, *N. F.*; Syrupus Bromidorum, *N. F.*

SODII CACODYLAS. U. S.

SODIUM CACODYLATE Sod. Cacodyl.

(sō′dĭ-ī că-cō-dȳ′lăs)

"Sodium dimethylarsenate [$Na(CH_3)_2AsO_2$ = 160.01], with a somewhat variable amount of water of crystallization. It contains not less than 72 per cent. nor more than 75 per cent. of $Na(CH_3)_2AsO_2$. Preserve it in well-closed containers." *U. S.*

This compound is prepared by heating together potassium acetate and arsenic trioxide which yields a distillate containing *cacodyl*, $As_2(CH_3)_4$, and *cacodyl oxide*, $As_2(CH_3)_4O$. This mixture is treated with an oxidizing agent which produces cacodylic acid, $(CH_3)_2AsO.OH$, which is then neutralized with sodium hydroxide, concentrated and crystallized.

"Sodium Cacodylate occurs as white, odorless, deliquescent prisms or as a granular powder. One Gm. of Sodium Cacodylate dissolves in about 0.5 mil of water and in about 2.5 mils of alcohol at 25° C. (77° F.). A solution of 2 Gm. of Sodium Cacodylate in 50 mils of distilled water requires not more than 0.5 mil of tenth-normal acid V.S. or tenth-normal alkali V.S. to render it neutral to phenolphthalein T.S. It melts in its water of crystallization at about 60° C. (140° F.), and becomes anhydrous at 120° C. (248° F.). The salt burns with a bluish flame, emitting a garlic-like odor. The salt imparts an intensely yellow color to a non-luminous flame. A mixture of a few drops of an aqueous solution of the salt (1 in 100) with 2 mils of hypophosphorous acid, allowed to stand in a stoppered tube, develops the odor of cacodyl within one hour. No turbidity is produced in 10 mils of an aqueous solution of the salt (1 in 20) by 1 mil of calcium chloride T.S., either in the cold or on heating (*monomethylarsenate*). No turbidity is produced in 5 mils of an aqueous solution of the

salt (1 in 20) by 2 mils of magnesia mixture T.S. within one hour (*arsenate or phosphate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Separate portions of an aqueous solution of the salt (1 in 50), acidulated with nitric acid, are not rendered turbid at once by silver nitrate T.S. (*chloride*) or by barium chloride T.S. (*sulphate*).

"**Assay.**—Dissolve about 2.5 Gm. of Sodium Cacodylate, accurately weighed, in distilled water, render the solution neutral to phenolphthalein T.S., if necessary, and then titrate with normal hydrochloric acid V.S., using methyl orange T.S. as indicator. It shows not less than 72 per cent. nor more than 75 per cent. of $Na(CH_3)_2AsO_2$.

"Each mil of normal hydrochloric acid V.S. used corresponds to 0.1600 Gm. of $Na(CH_3)_2AsO_2$. Each gramme of Sodium Cacodylate corresponds to not less than 4.5 mils nor more than 4.7 mils of normal hydrochloric acid V.S." *U. S.*

Uses.—Although cacodylic acid was employed as a therapeutic remedy by Jochheim in 1864, its popularity as a remedy may be dated from the writings of Gautier (*B. A. M.*, 1899, p. 604), since which time the salts of this acid have been used to a large extent in a number of conditions, chiefly those in which arsenic has been found to be of value.

Arsenic, like other poisonous elements, when bound up into a complex organic molecule in such a way that it does not ionize, no longer exercises its characteristic effects upon the bodily functions. Such a molecule is seen in cacodyl and various of its derivatives, such as sodium cacodylate. Although, in themselves, the cacodylates are relatively inert, in the course of their passage through the system they are in part slowly demethylized and yield more or less arsenious acid. For this reason they are capable of exercising the therapeutic effects of the inorganic forms of arsenic. Heffter (*A. E. P. P.*, xlvi, p. 230) has shown that a small, and not always constant proportion, ranging between two and three per cent. of the ingested dose of the arsenic is split off in the system, and eliminated in an inorganic form. This view is also sustained by the clinical study of Dawes and Jackson. (*J. A. M. A.*, 1907, xlviii, p. 2090.)

The range of demonstrated therapeutic usefulness of cacodylic acid is similar to that of arsenic. Its early popularity was achieved chiefly in the treatment of skin diseases, especially *psoriasis,* and in *tuberculosis.* In the latter condition it seems to act precisely as does arsenic, simply by improving the general nutritive state of the patient. There is also much clinical evidence of its value in various forms of *anemia, leukemia, asthma, chronic bronchitis, malaria,* and various other conditions in which arsenic is useful. It is especially employed in those conditions, such as *pernicious anemia,* in which it is desired to give very large doses of arsenic; Dawes (*J. A. M. A.*, 1911) reports a number of cases of this intractable infection which have been apparently cured, one having shown no symptoms for over three years. It has also been employed in *syphilis,* but the experimental investigations of Nichols (*J. A. M. A.*, 1911, lvi, p. 492) seem to demonstrate that it has no direct action upon the spirochetæ. It has also been employed in experimental *trypanosomiasis* (see Pflugholt, *M. M. W.*, 1910) with hopeful results. Besides the above conditions, it has been tried in the treatment of *carcinoma, leprosy,* and *pellagra,* but not to sufficient extent to allow of a positive conclusion as to its value. Although, as stated above, it is probable that cacodylic acid possesses no virtues which are not inherent in arsenic, it deserves recognition as a useful remedial agent. Its advantages over arsenous acid lie not merely in the fact of its lower toxicity, but especially in that it can be given hypodermically. If it be reduced in the system and arsenic eventually liberated, this change will not begin until after the remedy has passed the stomach, and probably does not occur to any large extent until after absorption, so that a comparatively large amount of arsenic can be introduced through the alimentary canal with little danger of deranging digestion. When given by the mouth, however, it generally imparts such a strong garlicky odor to the breath that this method of exhibiting the drug is rarely available.

Dose, one-fourth of a grain to two grains (0.016–0.13 Gm.).

SODII CARBONAS. Br.

SODIUM CARBONATE

(sō′dĭ-ī cär′bo-năs)

"Sodium Carbonate may be obtained from sodium chloride by interaction with ammonium bicarbonate, ignition, and subsequent crystallisation. It contains not less than 99 per cent. of pure sodium carbonate, $Na_2CO_3,10H_2O$." *Br.*

Carbonate of Soda, Sal Soda, Washing Soda; Natrium Carbonicum, *P. G.*; Carbonas Sodicus, Sal Sodæ; Carbonate de Soude pur cristallisé, *Fr. Cod.*; Einfach Kohlensaures Natron, Kohlensaures Natron, Soda, *G.*; Carbonato di sodio, *It.*; Carbonato sodico cristalizado, *Sp.*

Sodium carbonate is official in the U. S. P. IX only as *Sodii Carbonas Monohydratus.* (See page 1023.)

Native soda, sometimes called *natron,* is found in various parts of the world and exists either in the surface earth, which often exhibits a saline efflorescence, or in solution in small lakes, from which it is extracted by taking advantage of the drying up of the water during the heats of summer. (See *U. S. D.*, 19th edition, page 1136.)

Sodium carbonate is made from common salt by the older or Leblanc process in two steps; first, by converting the salt by sulphuric acid into sodium sulphate, and, secondly, by decomposing the sulphate by calcium carbonate and charcoal at a high temperature, so as to yield sodium carbonate. The chemical reactions may be summarized as follows:

$$2NaCl + H_2SO_4 = Na_2SO_4 + 2HCl$$
$$Na_2SO_4 + CaCO_3 + C_4 = Na_2CO_3 + CaS + 4CO$$

Within the last few decades a process has been put in practice which has given so much satisfaction in its results that it has superseded the hitherto unequalled process of Leblanc. It is designated the *ammonia-soda* process, and is based on the fact that when carbon dioxide is passed into a solution of common salt in aqueous ammonia a double decomposition occurs, and the slightly soluble sodium bicarbonate is precipitated:

$$NH_3 + CO_2 + NaCl + H_2O = HNaCO_3 + NH_4Cl$$

From the mother liquor containing the sal-ammoniac, if deemed advisable, the ammonia may be withdrawn by the action of lime, and serve in the renewal of the operation. The sodium bicarbonate is reduced by heat to the carbonate, and the carbon dioxide thus obtained serves to convert the ammonia into the ammonium bicarbonate necessary in the proceeding. The waste product here is calcium chloride, which takes with it all the chlorine of the salt originally used. Therefore if the ammonia-soda process were to replace the Leblanc process, hydrochloric acid and chlorine would have to be made independently, and would become much dearer than at present. To obviate this objection to the ammonia-soda process and to produce hydrochloric acid as one product of the same process, the late Walter Weldon proposed to use magnesia instead of lime in the decomposing of the sal-ammoniac. This would leave magnesium chloride instead of calcium chloride. From the magnesium chloride the chlorine can be obtained as follows:

$$MgCl_2 + H_2O = 2HCl + MgO$$

Steam will liberate hydrochloric acid from the magnesium chloride. This process is carried out practically at Salindres in France, although its economy is not definitely established.

A still more promising suggestion is that of the distinguished chemist Ludwig Mond of Brunner, Mond & Co., who are the chief English manufacturers of ammonia-soda. He proposes to freeze out the ammonium chloride from the mother liquors by artificial refrigeration, sublime it, and pass the vapor over magnesia, whereby the hydrochloric acid is retained in combination with the magnesia as magnesium chloride, while the ammonia passes on. The magnesium chloride is then heated in a current of air, when it is split up into chlorine and magnesia.

The reaction between ammonium bicarbonate and sodium chloride, upon which the ammonia process was founded, was first discovered by Dyar and Hemming about 1838, but it was only in 1863 that Ernest Solvay, a Belgian chemist, made it a practical success. The advantages of this method are that the sodium chloride is directly transformed into sodium carbonate, that in the precipitation sodium is the only metal thrown down, and that the preparation is therefore remarkably pure, that it is entirely exempt from the compounds of sulphur, that the amount of product is very large, that the apparatus used is very simple, that there is a great saving of fuel and of labor, and, finally, that no unwholesome gases are diffused in the atmosphere, interfering with the health of the workmen and the community. Schloesing and Rolland have observed that in the double decomposition between ammonium bicarbonate and sodium chloride a certain portion only—about two-thirds—undergoes the change. This is explained by Bauer, who finds that the reaction is limited by another in an inverse direction. Thus, if ammonium bicarbonate and sodium chloride yield sodium bicarbonate and ammonium chloride (hydrochlorate of ammonia), these, put together, inversely yield ammonium bicarbonate and sodium chloride. An equilibrium is thus established, and the mixture preserves a constant composition, at the point where the two reactions take place at the same time. (*J. P. C.*, Sept., 1874.)

Another source of sodium carbonate has been discovered in *cryolite*, a mineral existing in great abundance on the coast of Greenland, and largely imported into this country by a manufacturing company which enjoys to a certain extent a monopoly of the mineral under the Danish authorities. Cryolite consists mainly of a double aluminum and sodium fluoride, containing in 100 parts 13 of aluminum, 34 of sodium, and 53 of fluorine. Sodium carbonate is obtained by heating cryolite with lime, whereby calcium fluoride is formed, while the sodium and aluminum combine to form a sodium aluminate, a weak salt, which is dissolved out by lixiviation. The soda is converted into carbonate by passing carbon dioxide under pressure through the solution, and the alumina, separated from the soda, becomes insoluble, and is deposited. (*A. J. P.*, Jan., 1868, p. 71.) Cryolite is also largely used in Denmark and Germany in the preparation of sodium carbonate and of alumina, the latter of which is employed in the manufacture of alum and aluminum.

Besides the preparation of sodium carbonate, cryolite is employed for other important purposes. Within recent years it has become quite important as a flux for the electrolytic production of aluminum by the Hall and similar processes. (See *Alumen.*) Its only known locality, at least in large amount, is Greenland, where it is found on the southwest coast, near Cape Farewell, existing in beds, of which one is said to be eighty feet thick and three hundred long. It is imported by the "Pennsylvania Salt Manufacturing Company" into Philadelphia in immense quantities. It is a handsome mineral, hard, brittle, and translucent, sometimes almost transparent, but generally of a frosty whiteness, which probably suggested its name of *cryolite* or *kryolite*, from the Greek κρύος, *frost*. Though homogeneous in great degree, it exhibits here

and there in its substance dark spots, sometimes mere specks, sometimes of considerable size, which appear to be crystalline centers of substances mixed with it at the time of solidification, such as galena, ferrous carbonate, copper and iron pyrites, etc.

The different kinds of impure sodium carbonate, whether barilla, kelp, or soda-ash, being exceedingly variable in composition, it is important to determine by assay the amount of alkali which they contain. These various forms of carbonated soda are largely consumed in dyeing and bleaching, and in the manufacture of soap and glass.

Soda-ash is in white or gray masses, and contains about half its weight of foreign salts, consisting of sodium chloride and sodium sulphate.

Properties.—"Transparent, colorless, rhombic crystals, efflorescent. Taste strongly alkaline. Soluble in 2 parts of *water*. Aqueous solution strongly alkaline to *litmus*. Free from the impurities enumerated under 'Sodii Bicarbonas.' When heated it liquefies and then dries, losing 62.9 per cent. of its weight. 1 gramme requires for neutralisation not less than 13.8 millilitres of *N/2 solution of sulphuric acid. Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million. 20 grammes of Sodium Carbonate are neutralised by 9.8 grammes Citric Acid, and by 10.5 grammes of Tartaric Acid." *Br.*

This salt presents an anomaly in its solubility, as ascertained by Henri Loewel; it is more soluble in water at 36.1° C. (97° F.) than at its boiling point. Sodium carbonate is insoluble in alcohol. The most usual impurities in it are sodium sulphate and common salt, which may be detected by converting it into a nitrate and testing separate portions of this severally with barium chloride and silver nitrate. Common salt is seldom entirely absent, but good specimens are free from sodium sulphate. When badly prepared it is liable to contain sodium sulphide, which may be detected by the production of the odor of hydrogen sulphide upon dissolving the salt in water. Sodium carbonate is incompatible with acids, which decompose it with effervescence, acidulous salts, lime water, ammonium chlorid, and earthy and metallic salts. When crystallized it contains ten molecules of water. It is thus perceived that this salt, when crystallized, contains two-thirds of its weight of water; but the quantity actually present in it, as found in commerce, is variable, being dependent on the extent to which it may have undergone efflorescence. To obtain pure sodium carbonate for the purpose of a test, J. Lawrence Smith of Louisville, Ky., recommends that sodium oxalate should be prepared from the common carbonate, and then decomposed by heat.

Uses.—Soda being the natural alkali of the blood and other liquids of the human organism, its influence upon that organism in disease is very slight. In the experiments of Gradeau the injection of 107 grains of sodium carbonate directly into the blood of a dog produced practically no symptoms, and in the studies of Münch upon the effect on the human system of the continuous exhibition for a few days of large amounts of soda the results were almost entirely negative. The chief influence of the salt is upon certain of the liquid excretions. Thus, the urine becomes distinctly alkaline, without, however, so far as we know, there being any distinct change in its general constituents. The experiments of Lewaschen prove that soda salts given to dogs with biliary fistula increase very markedly the liquidity of the bile and diminish the percentage of solids in it. These experiments are in accord with clinical experience, which shows that the alkaline sodium salts, given one to two hours after meals in full dose, are of decided value in the treatment of *gall-stones* and various affections associated with excessive acidity of the biliary secretion. On account of its having no general effect upon the system, soda and its carbonates are superior to potassium as simple alkaline remedies. When, therefore, it is desired to overcome *acidity of the stomach or intestines*, or to render acid urine alkaline, these preparations are very available. The bicarbonate is, however, usually preferred to the carbonate as being less likely to irritate the stomach. Alkaline sodium salts are also employed with advantage, internally and externally, in *skin diseases*, especially those of a papulous and scaly character. A lotion suitable for these cases may be formed by dissolving from two to three drachms of the carbonate in a pint of water. For a bath, from eight to sixteen ounces of the salt may be dissolved in the necessary quantity of water. In recent *burns* without much destruction of the skin, the free application of a saturated solution will usually give immediate relief. When swallowed in an overdose, it acts as an irritant poison. The best antidotes are the fixed oils, acetic acid, and lemon juice.

Dose, from five to thirty grains (0.32–2.0 Gm.).

SODII CARBONAS EXSICCATUS. Br.

EXSICCATED SODIUM CARBONATE

(sō'dĭ-ī cär'bo-năs ĕx-sĭc-cā'tŭs)

"Exsiccated Sodium Carbonate is obtained by heating Sodium Carbonate until it loses nearly 63 per cent. of its weight. It contains not less than 95 per cent. of pure anhydrous sodium carbonate, Na_2CO_3." *Br.*

Dried Carbonate of Soda; Exsiccated Sodium Carbonate; Carbonate de Soude sec du commerce, *Fr. Cod.*; Natrium carbonicum siccum, *P. G.*; Getrocknetes Natriumcarbonat, Entwässerte Soda, *G.*; Carbonato sodico seco, *Sp.*

The dried sodium carbonate (*Natrium Carbonicum Siccum*) of the *P. G. V* contains about 75 per cent. of anhydrous sodium carbonate and corresponds to the formula $Na_2CO_3 + 2H_2O$. This is not as stable a form as the U. S. P. monohydrated salt.

Sodium carbonate contains ten molecules of water of crystallization, and, when heated, readily undergoes aqueous fusion. Upon continuing the heat, the water is driven off, and a white porous mass remains, which is easily reduced to powder. Dried sodium carbonate is in the form of a white powder, and differs in nothing from the crystallized, except in being devoid of water of crystallization. (See *Sodii Carbonas.*) It is officially described as "a whitish powder. Taste strongly alkaline. Yields the *reactions* characteristic of sodium and of carbonates. 1 gramme requires for neutralisation not less than 17.9 millilitres of *N/1 solution of sulphuric acid. Lead limit* 25 parts per million. *Arsenic limit* 5 parts per million." *Br.* (See *Sodii Carbonas Monohydras.*)

Uses.—This preparation has the advantage over the common carbonate that it admits of being made into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the crystallized carbonate, the dose of the dried salt must be reduced in proportion. For the medicinal properties of this salt, see *Sodii Carbonas.*

Dose, two to ten grains (0.13–0.65 Gm.) may be given three times a day, in the form of pill prepared with soap and aromatics.

SODII CARBONAS MONOHYDRATUS. U. S.

MONOHYDRATED SODIUM CARBONATE
Sod. Carb. Monohyd.

(sō′dĭ-ī căr′bo̤-năs mō-no̤-hȳ-drā′tŭs)

"It contains not less than 99.5 per cent. of $Na_2CO_3 + H_2O$ (124.02). Preserve it in well-closed containers." *U. S.*

Preparation.—This salt was introduced into the U. S. P. VIII, upon the recommendation of Coblentz and Frerichs, on account of its much greater stability when compared with sodium carbonate; it contains but one molecule of water of crystallization, while the ordinary carbonate contains ten; as it is almost impossible to keep the carbonate without efflorescing, it became difficult to use it for chemical or pharmaceutical purposes without previously determining the quantity of water present. Coblentz ascertained by experiment that by exposure in an open vessel, monohydrated sodium carbonate gained the first week 0.14 per cent. of moisture, this increased to 0.16 per cent. by the second week. It is prepared by heating and crystallizing sodium carbonate at a temperature above 35° C. (95° F.). As it can be prepared commercially at a low price of excellent quality and is in the form of granular crystals its introduction into the Pharmacopœia has proved a great convenience. It may be used in the place of sodium carbonate.

Properties.—It is officially described as "a white, crystalline, granular powder; odorless, and having a strongly alkaline taste. When exposed to the air, under ordinary conditions, it absorbs only a slight percentage of moisture; exposed to warm, dry air at or above 50° C. (122° F.), the salt effloresces, and at 100° C. (212° F.) it becomes anhydrous. One Gm. of Monohydrated Sodium Carbonate dissolves in 3 mils of water, and in 7 mils of glycerin at 25° C. (77° F.); also in 1.8 mils of boiling water; insoluble in alcohol. An aqueous solution of the salt (1 in 10) is strongly alkaline to litmus and phenolphthalein T.S., and effervesces with acids. An aqueous solution of the salt imparts an intensely yellow color to a non-luminous flame. An aqueous solution of the salt (1 in 50), mixed with a slight excess of hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3).

"Assay.—Dissolve about 2.5 Gm. of Monohydrated Sodium Carbonate, accurately weighed, in about 25 mils of distilled water and titrate with normal sulphuric acid V.S., methyl orange T.S. being used as indicator. It shows not less than 99.5 per cent. of $Na_2CO_3 + H_2O$.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.06201 Gm. of $Na_2CO_3 + H_2O$. Each gramme of Monohydrated Sodium Carbonate corresponds to not less than 16.05 mils of normal sulphuric acid V.S." *U. S.*

Uses.—Monohydrated sodium carbonate can be used for the same purposes that sodium carbonate can, in the proportion of 1 of the former to 2.3 of the latter. (See *Sodii Carbonas,* page 1022.) For internal use it may replace the exsiccated sodium carbonate, being nearly identical with it in composition. (See *Sodii Carbonas Exsiccatus,* page 1023.)

Dose, two to ten grains (0.13–0.65 Gm.).

SODII CHLORIDUM. U. S., Br.

SODIUM CHLORIDE **Sod. Chlorid.**

(sō′dĭ-ī ȼhlō′rĭ-dŭm)

"It contains, when dried to constant weight at 110° C. (230° F.), not less than 99 per cent. of NaCl (58.46). Preserve it in well-closed containers." *U. S.* "Sodium Chloride, NaCl, may be obtained by purifying common salt." *Br.*

Chloruretum Sodicum, Sal Commune, s. Culinare; Table Salt; Muriate of Soda, Sea Salt, Salt; Chlorure de Sodium purifié, *Fr. Cod.;* Hydrochlorate de Soude, Sel commun, Sel de Cuisine, Sel marin, *Fr.;* Natrium Chloratum, *P. G.;* Natriumchlorid, Chlornatrium, Kochsalz, *G.;* Cloruro di sodio, Sal commune, *It.;* Cloruro sodico, Sal comun, *Sp.*

This mineral production, so necessary to mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it, and from its frequent presence in the solids and fluids of the animal economy, it may be supposed to perform an important part in assimilation and nutrition.

Natural State.—Common salt exists in nature either in the solid state or in solution. In the solid state, called *rock salt, fossil salt,* and *sal gemmæ,* it is often found forming extensive beds, and even entire mountains, from which it is extracted in blocks or masses by mining operations. Its geological position

is very constant, it occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it exists in certain springs and lakes, and in the waters of the ocean. The principal salt mines are found in Poland, Hungary, and Russia; in various parts of Germany and Austria, particularly the Tyrol; in Cheshire, England; in Spain; in various parts of Asia and Africa; in Turk's island near St. Domingo; and in Peru and other countries of South America. There are but few mines in the United States where rock salt is produced—at present, one in Louisiana, two in Kansas, and a group operated by one company in the western part of the State of New York; but there are numerous salt springs, which either flow naturally or are produced artificially by sinking wells to various depths in places where salt is known to exist. These are found principally in Missouri, Kentucky, Illinois, Ohio, Michigan, Pennsylvania, Virginia, West Virginia, and New York. In the last-mentioned State the springs are the most productive, the chief ones being situated at Salina, Montezuma, and Galen. In West Virginia an important salt region exists, extending fifteen miles on both sides of the Great Kanawha River, and in Michigan in the counties of Huron, Bay, Wayne, and Saginaw extensive salt wells are worked. California is the only one of the United States in which sea water is utilized for salt production by solar evaporation; this is done extensively at San Diego Bay. The production in the United States in 1915 amounted to 38,231,496 barrels of 280 pounds each.

Rock salt is always transparent or translucent; but it often exhibits various colors, such as red, yellow, brown, violet, blue, etc., which are supposed to be derived from iron and manganese.

Extraction.—Mines of salt are worked in two ways. When the salt is pure, it is merely dug out in blocks and thrown into commerce. When impure, it is dissolved in water, and extracted afterwards from the solution by evaporation. When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine and the temperature of the place where it is found. When the water contains from 14 to 15 per cent. of the salt, it is extracted by evaporation in open pans or vacuum pans provided with crystallizing boxes. If, however, it contains only 2, 3, 4, or 5 per cent., the salt is obtained in a different manner. If the climate be warm, it may be procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of evaporation, to be mentioned presently, and the subsequent application of artificial heat.

Sea water is a weak saline solution, containing approximately 2.7 per cent. of common salt, which is extracted by the agency of solar heat in warm countries. Salt thus obtained is called *bay salt*. The extraction is conducted in Europe principally on the shores of the Mediterranean, the waters of which are saltier than those of the open ocean. The mode in which it is performed is by letting the sea water into shallow dikes, lined with clay, and capable, after having been filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. About 40,000 tons a year are thus made at San Diego, California, the only place in the United States where solar evaporation is carried out. In temperate climates, weak brines are first concentrated in buildings called *graduation houses*. These are rough wooden structures open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of brushwood somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the brushwood, upon which it is allowed to fall, and in its descent, it becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and, being repeated several times, the solution is at last brought to the requisite degree of strength to permit of its final concentration in iron boilers by artificial heat.

A very interesting and valuable article describing the American salt industry and very well illustrated with photographs will be found in the *American Food Journal* for December, 1916.

Properties.—Sodium chloride is white, without odor, and of a peculiar taste called saline. It is usually crystallized in cubes; but by quiet evaporation it often assumes the form of hollow quadrangular pyramids, or hopper-shaped crystals, consisting of an aggregation of cubes. It is officially described as follows: "Sodium Chloride occurs as colorless, transparent, cubical crystals, or as a white, crystalline powder; odorless, and having a purely saline taste. It is usually slightly hygroscopic. One Gm. of Sodium Chloride dissolves in 2.8 mils of water, and in 10 mils of glycerin at 25° C. (77° F.); also in 2.7 mils of boiling water; slightly soluble in alcohol. An aqueous solution of the salt (1 in 10) is neutral to litmus. When heated the salt decrepitates. At a red heat it fuses, and at a white heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intensely yellow color. With silver nitrate T.S. an aqueous solution of the salt (1 in 20) yields a white, curdy precipitate, insoluble in nitric acid, but readily soluble in ammonia water. An aqueous solution of Sodium Chloride does not respond to the Test for heavy metals (see Part III, Test No. 3). Separate portions of 10 mils each of an aqueous solution of Sodium Chloride (1 in 100), after the addition of 1 mil of ammonia water, show no immediate turbidity upon the addition of ammonium oxalate T.S. (*calcium*) or of sodium phosphate T.S. (*magnesium*). Digest 2 Gm. of the finely powdered salt for three hours with 25 mils of warm alcohol, cool the mixture and remove the undissolved salt by filtration. Evaporate the filtrate to dryness, dissolve the residue in 5 mils of distilled

water, add 1 mil of chloroform, and cautiously introduce, drop by drop, with constant agitation, chlorine T.S. which has been diluted with twice its volume of distilled water. The chloroform does not acquire a violet, yellow, or orange color (*iodide or bromide*).

"**Assay.**—Proceed as directed under the Assay for chlorides (see Part III, Test No. 5), using about 0.25 Gm. of Sodium Chloride, dried to constant weight at 110° C. (230° F.) and accurately weighed. It shows, in the dried salt, not less than 99 per cent. of NaCl.

"Each mil of tenth-normal silver nitrate V.S. corresponds to 0.005846 Gm. of NaCl. Each gramme of Sodium Chloride, previously dried, corresponds to not less than 169.3 mils of tenth-normal silver nitrate V.S." *U. S.*

"Small, white, crystalline grains, or transparent, cubic crystals, free from moisture. Taste saline. Soluble in 3 parts of *water*. Yields the *reactions* characteristic of sodium and of chlorides. Yields no characteristic *reactions* for potassium, bromides, or iodides, and not more than slight *reactions* for calcium, magnesium, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million. 20 millilitres of an aqueous solution (1 in 20) are not immediately colored blue by 0.5 millilitre of *solution of potassium ferrocyanide* (limit of iron)." *Br.*

S. Hill (*Ph. Post.*, 1912, p. 37) states that the flame test for potassium in sodium chloride is unreliable, especially as a great deal of the blue glass gives fallacious results owing to its unsuitability. He recommends the use of *Koevenagel's reagent* of *cobalt sodium hexanitrite*, which produces a yellow precipitate in potassium solutions as dilute as 1-2000.

When pure, salt undergoes no change in the air; but when contaminated with magnesium chloride, as not unfrequently happens, it is deliquescent. Exposed to a gradually increasing heat, it first decrepitates from the presence of interstitial moisture, next melts, and finally volatilizes in white fumes with but partial decomposition. It is decomposed by several of the acids, particularly sulphur and nitric, which disengage vapors of hydrochloric acid; by potassium carbonate with the assistance of heat; and by silver nitrate and mercurous nitrate. In contact with iron, in the presence of air and moisture, it undergoes decomposition. It is decomposed by steam excessively heated, with the escape of hydrochloric acid and an alkaline residue. Several varieties of common salt are distinguished in commerce, as *stored salt, fishery salt, bay salt*, etc.; but they are characterized by the size and compactness of the grains, and not by any difference in composition.

Sodium chloride is incompatible with mercurous, lead, and silver salts with the formation of the corresponding insoluble metallic chloride.

Composition.—Common salt, in its pure state, consists of one atom of chlorine and one of sodium. It contains no water of crystallization. The common salt of commerce, besides pure sodium chloride, contains, generally speaking, insoluble matter, and usually more or less calcium and magnesium sulphates and calcium and magnesium chlorides. When pure, it is not precipitated by sodium carbonate, barium chloride, or potassium ferrocyanide. Calcium chloride is generally present in very small amount; but the magnesium chloride sometimes amounts to 28 parts in 1000. Calcium sulphate is usually present, constituting variously from 1 to 23½ parts in 1000, and magnesium sulphate is sometimes present and sometimes absent. To separate the earths, a boiling solution of sodium carbonate must be added as long as any precipitate is formed. The earths will form as carbonates, and must be separated by filtration, and the sodium sulphate and sodium chloride resulting from the double decomposition will remain in solution. The sodium sulphate may then be decomposed by the cautious addition of barium chloride, avoiding excess, which will generate sodium chloride and insoluble barium sulphate.

Uses.—Although sodium chloride, like other salines, is capable of exercising a diuretic and cathartic action, because of its rapid diffusibility it is much inferior to many other substances. Common salt has for many years been a household remedy in the treatment of *hemoptysis* in doses of one teaspoonful (3.9 Gm.) taken dry. The observations of Belden (*Z. E. P. T.*, 1909, vii, p. 290) lend support to this employment; he found that although when mixed with the blood outside of the body it had no effect, when administered either by the stomach or by injection it increased the coagulability of the blood. He believed the effect to be due to alteration in the concentration of the blood. Externally applied in solution it is stimulant and may be used either locally or generally. Locally it has been employed in the form of fomentations in *sprains* and *bruises*. Salt baths are used for their tonic and exciting effect in various diseases, especially when attended with weakness of the circulation. A pound of salt to four gallons of water forms a solution of about the strength of sea water and suitable for a bath. (See also under *Aqua*, p. 164.) Because of its physiological inertness sodium chloride is the substance generally preferred to increase the density of water when for any reason it is desired to inject that fluid directly into the vein (see *Liquor Sodii Chloridi Physiologicus*).

The uses of common salt in domestic economy as a condiment and an antiseptic are well known.

Dose, as a cathartic, from two drachms to half an ounce (7.7–15.5 Gm.); as an emetic, from half an ounce to an ounce (15.5–31 Gm.), dissolved in four or five times its weight of water. It is frequently used as a clyster, two tablespoonfuls in a pint of water.

SODII CITRAS. U. S.

SODIUM CITRATE Sod. Cit.

(sō'dĭ-ī cī'trăs)

"It contains not less than 98 per cent. of $Na_3C_6H_5O_7 + 2H_2O$ (294.07). Preserve it in well-closed containers." *U. S.*

Citrate of Soda; Citras Sodicus; Citrate de Soude, *Fr.*; Natrium Citricum; Natriumcitrat, Citronsaures Natron, *G.*

Preparation.—The official salt is the normal salt of citric acid and sodium, there being three possible combinations owing to the tri-fold basicity of citric acid. It may be made by adding to a hot aqueous solution of 59 parts of citric acid an aqueous solution of 53 parts of monohydrated sodium carbonate, neutralizing, evaporating, and crystallizing.

Properties.—It is officially described as "in small crystals or as a white, granular powder; odorless, and having a cooling, saline taste. One Gm. of Sodium Citrate dissolves in 1.3 mils of water at 25° C. (77° F.); also in 0.6 mil of boiling water; insoluble in alcohol. An aqueous solution of Sodium Citrate (1 in 20) is slightly alkaline to litmus but is not reddened by 1 drop of phenolphthalein T.S. When heated to about 150° C. (302° F.), the salt loses all of its water of crystallization; on ignition at a red heat, it carbonizes and emits inflammable gases which have a very pungent, acrid odor, and a residue remains which is alkaline to litmus and strongly effervesces with acids. To a non-luminous flame, the salt imparts an intensely yellow color. Mix 10 mils of an aqueous solution of the salt (1 in 20) with 10 mils of calcium chloride T.S.; the liquid remains clear until it is boiled, when a white, granular precipitate is produced. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

Assay.—Proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows not less than 98 per cent. of $Na_3C_6H_5O_7 + 2H_2O$.

"Each mil of half-normal sulphuric acid V.S. used corresponds to 0.04901 Gm. of $Na_3C_6H_5O_7 + 2H_2O$. Each gramme of Sodium Citrate corresponds to not less than 20 mils of half-normal sulphuric acid V.S." *U. S.*

Uses.—Sodium citrate, like the potassium salt, is oxidized in the system and appears in the urine in the form of a carbonate, and may therefore be used to overcome excessive acidity of the urine. Lichtwitz (*Th. M.*, 1911, xxv, p. 81) recommends it especially in the treatment of *diabetic acidosis* instead of the carbonates. When added to the blood outside of the body it prevents coagulation, presumably by the formation of non-ionizing calcium citrate. In the same way it prevents the curdling of milk by rennin, the sodium caseinate which is formed by this ferment after the addition of the citrate being soluble. According to Robertson and Burnett (*J. P. Ex. T.*, 1912, lix), when administered in large doses to mammals it causes severe symptoms by depriving the tissues of ionizable calcium. While it has been experimentally shown that the administration of sodium citrate by the mouth may delay the coagulability of the blood, it is improbable that any severely toxic symptoms can be caused by its oral administration.

Sodium citrate may be used for the various purposes to which potassium citrate is put (see *Potassium Citrate*), but is probably somewhat less efficient as a diuretic or diaphoretic. It is widely employed in the modification of cow's milk for infant feeding for the purpose of preventing the formation of large hard curds. For this purpose from one to two grains of the salt may be added to each ounce of milk used in the mixture. It has also been highly lauded by Weaver (*New Orleans Med. and Surg. Journ.*, lxc) in the treatment of *pneumonia*. Wright reported remarkable results from its use as a local application for *furunculosis*. *Wright's solution* consists of sodium citrate, 2 grains, sodium chloride, 20 grains, water, 1 ounce; cotton saturated with this solution is placed over the boil and covered with waxed paper to prevent evaporation.

Dose, fifteen to sixty grains (1.0–3.9 Gm.).

SODII CITRO-TARTRAS EFFERVESCENS. Br.

EFFERVESCENT SODIUM CITRO-TARTRATE

(sō'dĭ-ī cī'trō-tär'trăs ĕf-fĕr-vĕs'cĕns)

"Sodium Bicarbonate, in powder, 510 *grammes;* Tartaric Acid, in powder, 270 *grammes;* Citric Acid, in powder, 180 *grammes;* Refined Sugar, in powder, 150 *grammes.* Mix the powders thoroughly; place the mixture in a dish or pan of suitable form heated to between 90° and 105° C. (194° and 221° F.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. (131° F.). The product weighs about one thousand grammes." *Br.*

The object of this combination is to furnish sodium citrate and tartrate in a convenient and portable form. As the water has been driven off by heat, no reaction takes place until dissolved in water, when the two acids combine with the soda of the bicarbonate to produce sodium tartrate and citrate, and the carbon dioxide escapes with brisk effervescence. It is in this form that the preparation is intended to be used.

It may be mixed with unpleasant salines whose taste it hides by effervescence. In full dose it has a laxative action similar to that of Seidlitz powders.

Dose, one to two drachms (3.9–7.7 Gm.), which may be taken in a small wineglassful or more of water, and repeated occasionally as required.

SODII CYANIDUM. U. S.

SODIUM CYANIDE Sod. Cyanid.

(sō′dĭ-ī cȳ-ăn-ī′dŭm)

"It contains not less than 95 per cent. of Na CN (49.01). Preserve it in well-closed containers, protected from light." *U. S.*

NOTE.—Sodium Cyanide replaces potassium cyanide of the U. S. P. VIII.

Sodium cyanide may be made by various processes, all of which are analogous to those for the potassium salt. (See *Potassii Cyanidum.*) One of the most recent methods, however, is by the fusion of calcium cyanide with sodium carbonate, $NC.NCCa + Na_2CO_3 = 2NaCN + CaCO_3$.

Potassium cyanide has been very extensively used in the arts and was often adulterated. In addition to this, its excessive tendency to absorb moisture has caused it to be replaced by sodium cyanide, which, on account of the lower atomic weight of sodium, makes it technically stronger weight for weight in the content of hydrocyanic acid. In addition to this, the higher price and scarcity during the European War of potassium salts have justified the introduction of sodium cyanide into the U. S. P. IX.

"Sodium Cyanide occurs in the form of white, opaque, amorphous pieces, or as a white, granular powder; odorless when perfectly dry; deliquescent in the air and exhaling the odor of hydrocyanic acid. *Great caution must be used in handling this salt.* It is freely soluble in cold water. An aqueous solution of the salt (1 in 20) is strongly alkaline to litmus, and emits the odor of hydrocyanic acid. At a low red heat the salt fuses. To a non-luminous flame it imparts an intensely yellow color. A few drops of a solution of the salt (1 in 20) yield with silver nitrate T.S. a white precipitate, which is soluble in an excess of the solution of Sodium Cyanide, and in ammonia water. Shake 5 mils of a solution of the salt (1 in 20) with a few drops each of ferrous sulphate T.S. and of ferric chloride T.S., and then add a slight excess of hydrochloric acid; a blue precipitate (iron ferrocyanide) is produced. In 5 mils of an aqueous solution of the salt (1 in 10) a drop of ferric chloride T.S. followed by 2 mils of diluted hydrochloric acid produces neither a dark blue color (*ferrocyanide*) nor a red color (*sulphocyanate*).

"**Assay.**—Dissolve about 0.45 Gm. of Sodium Cyanide, accurately weighed, in 25 mils of distilled water, add 4 mils of ammonia water, 3 drops of potassium iodide T.S. and titrate with tenth-normal silver nitrate V.S. to the production of a permanent precipitate. It shows not less than 95 per cent. of NaCN.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.009802 Gm. of NaCN. Each gramme of Sodium Cyanide corresponds to not less than 96.9 mils of tenth-normal silver nitrate V.S." *U. S.*

Uses.—Sodium cyanide acts upon the system as does prussic acid. (See *Acidum Hydrocyanicum Dilutum.*) It is rarely used as a medicine. Five grains of it may be regarded as a usual fatal dose (see Venghauss, *A. Pharm.*, clii, p. 138), although smaller doses may occasionally take life. Sodium cyanide has the power of dissolving silver oxide and may be used for the removal of silver nitrate stains from clothing. According to Guthrie, a solution of three grains (0.2 Gm.) to the ounce (30 mils), dropped in the eye every other day, will remove olive colored stains from the conjunctiva caused by silver nitrate.

Owing to the large use of the cyanides for the recovery of gold and other technical purposes, numerous accidental cases of poisoning have occurred. The symptoms and treatment of these are precisely the same as outlined under *Acidum Hydrocyanicum.*

Dose, one-eighth of a grain (0.008 Gm.).

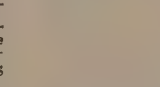
SODII GLYCEROPHOSPHAS. U. S.

SODIUM GLYCEROPHOSPHATE Sod. Glycerophos. [Sodium Glycerinophosphate]

(sō′dĭ-ī glȳ-cę-rō-phŏs′phăs)

"Hydrated Sodium Glycerophosphate containing not less than 68 per cent. of the anhydrous salt [$Na_2C_3H_7PO_6$ or $C_3H_5(OH)_2PO_4Na_2 = 216.10$]." *U. S.*

Sodium glycerophosphate which formerly existed as a pasty mass can now be found in commerce in solid plates or scales which renders it more convenient for pharmaceutical use. It is made by treating glycerophosphoric acid with sodium hydroxide in a manner similar to the process for calcium glycerophosphate. The official sodium glycerophosphate is the normal salt having the following structural composition, exclusive of water of hydration:



The theoretical acid salt has never been prepared in a solid form. The special salt, like the calcium salt of the same acid (which see), is found in several commercial forms, varying in the amount of water of hydration present. Some of these are solid and others liquid. As is the case with the calcium salt, greater solubility is conferred upon the product by the presence of a small proportion of some organic acid such as citric or lactic.

It is officially described as "white, monoclinic plates or scales, or as a white powder, having a saline taste; odorless. It is very soluble in cold or hot water; nearly insoluble in alcohol. An aqueous solution of the salt (1 in 20) is alkaline to litmus and to phenolphthalein T.S. When strongly heated the salt is decomposed, evolving inflammable vapors, and at a red heat is converted into sodium pyrophosphate. Dissolve 1 Gm. of Sodium Glycerophosphate in 10 mils of distilled water and add 3 drops of phenolphthalein T.S.; the red color produced is

discharged by the addition of 1.5 mils of tenth-normal sulphuric acid V.S. (*free alkali*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Add an equal volume of cold ammonium molybdate T.S. to 10 mils of an aqueous solution of the salt (1 in 20); no precipitate is formed within one hour (*phosphates*). On heating this mixture a yellow precipitate is formed. Triturate 1 Gm. of the salt with 20 mils of dehydrated alcohol, filter the mixture, evaporate the filtrate on a water bath and dry the residue for one hour at a temperature not exceeding 70° C. (158° F.); the weight of this residue does not exceed 0.01 Gm. (*alcohol-soluble impurities*).

"**Assay.**—Dissolve about 3 Gm. of the salt, accurately weighed, in 30 mils of distilled water and titrate with half-normal hydrochloric acid V.S., using methyl orange T.S. as indicator. It shows not less than 68 per cent. of $Na_2C_3H_7PO_6$.

"Each mil of half-normal hydrochloric acid V.S. used corresponds to 0.10805 Gm. of $Na_2C_3H_7PO_6$. Each gramme of Sodium Glycerophosphate corresponds to not less than 6.29 mils of half-normal hydrochloric acid V.S." *U. S.*

Uses.—The glycerophosphates have been used in medicine on the supposition that being more nearly allied chemically to the form in which phosphorus is found in the body, they would be more easily utilized in conditions of depraved phosphorus nutrition and thereby aid in the upbuilding of nerve strength. It seems well established that when taken by the mouth they are absorbed unchanged but, according to Marfori (*A. E. P. P.*, Schmiedeberg Festsch., 1908, p. 378), when injected subcutaneously they are rapidly excreted by the kidneys. The glycerophosphoric acid absorbed from the alimentary tract is retained for some days but is slowly decomposed in the body, being eliminated through the urine as inorganic phosphate. It is probable that the system is capable of utilizing a portion of the glycerophosphoric acid, synthesizing from it the complex organic bodies in which phosphorus exists in the tissues. But the same thing is true of sodium phosphate. Whether glycerophosphate has any higher nutritive value than inorganic phosphates is extremely doubtful. Forbes (*Ohio Technical Bull.* No. 6, 1914), in an elaborate research upon swine, reaches the conclusion that there is no fundamental differences in the nutritive values of the glycerophosphates and phosphates, except that the former are less likely to disturb the digestive tract. In a review of the literature on this subject for the Council on Pharmacy and Chemistry, Marshall (*J. A. M. A.*, 1915, lxiv, p. 573) concluded "that organic phosphorus is of no more value as a food than inorganic." Granting this be true, however, does not necessarily disprove their therapeutic utility. It is possible to conceive that the unbroken molecule of glycerophosphoric acid, circulating in the blood, may in some way exercise a stimulating action on the metabolism of the central nervous system. While there is considerable clinical evidence of the value of the glycerophosphates in various conditions of depraved metabolism, such as *neuralgia, neurasthenia, senility, Graves's disease,* etc., the testimony is not unanimous. We must regard, therefore, the value of sodium glycerophosphate as a remedy in conditions of general debility as still *sub judice.* It has the advantage over the calcium salt that being soluble it may be administered in liquid form.

Dose, ordinarily ten to thirty grains (0.65–2.0 Gm.), although much larger quantities may be given safely.

Off. Prep.—Liquor Sodii Glycerophosphatis, *U. S.;* Elixir Calcii et Sodii Glycerophosphatum (from Solution), *N. F.;* Elixir Glycerophosphatum Compositum (from Solution), *N. F.*

SODII HYDROXIDUM. U. S.

SODIUM HYDROXIDE Sod. Hydrox. [Sodium Hydrate, Caustic Soda, U. S. 1890]

(sō'dī-ī hȳ-drŏx'ĭ-dŭm)

"It contains not less than 90 per cent. of Na OH (40.01). Preserve it in well-closed containers. If bottles are used as containers they must be made of hard glass." *U. S.* "Sodium Hydroxide of commerce purified by means of alcohol." *Br.,* 1914 Appendix.

Soda Caustica; Hydrate of Soda; Natrium Causticum, s. Hydricum; Soude caustique, *Fr. Cod.;* Natron, Aetznatron, *G.;* Soda caustica, *It.;* Hidrato sodico, *Sp.*

The solution of *sodium hydroxide,* being a solution of the caustic alkali, yields it on evaporation in the solid state. Metallic vessels are used in consequence of the chemical action of soda on earthenware or porcelain, and the product is directed to be kept in green glass bottles because these resist its action better than those of white glass. Sodium hydroxide is usually poured into cylindrical moulds to harden, or allowed to solidify in mass, and broken into irregular fragments.

Sodium hydroxide, sodium hydrate, or "caustic soda," of commerce, occurs in hard grayish-white rods or cakes, deliquescent, very alkaline and corrosive. It affords the reactions characteristic of sodium. It usually contains as impurities alumina, carbonates, chlorides, phosphates, and sulphates.

Purified Sodium Hydroxide may be obtained by dissolving caustic soda in ethylic alcohol, filtering the solution, evaporating it to dryness in a silver dish, occasionally adding distilled water during the evaporation. The residue is *Purified Sodium Hydroxide.* It should yield no characteristic reaction with the tests for phosphates or sulphates, and not more than the slightest reactions with the tests for carbonates. It is not quite free from alumina.

Sodium hydroxide has been made on a large scale by simply modifying the Leblanc process (see *Sodii Carbonas*), so that more coal is added in the black-ash fusion, when carbonate is reduced to hydroxide with the liberation of car-

bon monoxide by the action of the quick-lime, the reactions being:

$$CaCO_3 + C = CaO + 2CO$$
$$Na_2CO_3 + CaO + H_2O = 2NaOH + CaCO_3$$

It is also made like the corresponding compound, caustic potash, by the decomposition of sodium carbonate in solution by quick-lime. (See *Liquor Sodii Hydroxidi.*) Ammonia soda ash when causticised yields a purer caustic than Le Blanc soda as it is freer from sulphur impurities. It may also be purified from carbonate, and from lime salts and other impurities, as the potassium hydroxide is purified by treatment with alcohol, which dissolves the alkali, but leaves the salts insoluble. (See *Sodii Carbonas,* page 1021.) H. A. Frasch devised a method for caustic soda in which nickel hydroxide acts upon sodium chloride in the presence of an excess of ammonia; a double nickel-ammonium chloride ($Ni(NH_3)_2Cl_2 + 4NH_3$) separates as a violet, crystalline mass leaving caustic soda in the solution. Both the nickel and the ammonia are regenerated.

The manufacture of caustic soda by electrolytic means from brine in the United States has developed very greatly within the last few years.

Properties.—It is officially described as in "dry, white, or nearly white, fused masses, or sticks, hard and brittle, showing a crystalline fracture; odorless. *Great caution is necessary in using it,* as it rapidly destroys organic tissues. Exposed to the air, it deliquesces, absorbs carbon dioxide, and becomes covered with a coating of carbonate. One Gm. of Sodium Hydroxide dissolves in 0.9 mil of water at 25° C. (77° F.); also in about 0.3 mil of boiling water; very soluble in alcohol. A solution of Sodium Hydroxide even when greatly diluted is strongly alkaline to litmus. When introduced into a non-luminous flame, it imparts to it an intensely yellow color. An aqueous solution of Sodium Hydroxide (1 in 20) is clear and colorless (*organic matter or insoluble impurities*), and, after being acidulated with acetic acid, it yields no precipitate on the addition of an excess of tartaric acid T.S., or upon the addition of a few drops of sodium cobaltic nitrite T.S. (*potassium*). An aqueous solution of Sodium Hydroxide (1 in 50), slightly acidulated with hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dissolve in a 500 mil graduated flask about 10 Gm. of Sodium Hydroxide, accurately weighed in a glass-stoppered weighing-bottle, in 250 mils of distilled water, which has previously been boiled and cooled, and add 15 mils of barium chloride T.S. Fill the flask to the mark with distilled water, which has previously been boiled and cooled, and thoroughly agitate the liquid. Filter it through a dry filter into a dry flask (rejecting the first 20 mils) and titrate 100 mils of the clear filtrate with normal hydrochloric acid V.S., using phenolphthalein T.S. as indicator. It shows not less than 90 per cent. of NaOH.

"Each mil of normal hydrochloric acid V.S. used corresponds to 0.04001 Gm. of NaOH. Each gramme of Sodium Hydroxide corresponds to not less than 22.5 mils of normal hydrochloric acid V.S." *U. S.*

Sodium hydroxide as found in commerce is in grayish-white fragments, opaque, brittle, and extremely corrosive. It is deliquescent, very soluble in water, soluble in alcohol, and possessed of all the alkaline properties of potassium hydroxide, from which it differs in imparting a yellow color to flame, and in not giving in solution a yellow precipitate with platinic chloride or a crystalline precipitate with tartaric acid in excess. When heated it melts, and at an intense heat evaporates. Though deliquescent, like potassium hydroxide, it does not, like that alkali, become permanently liquid, but forms a paste, which after a time effloresces. The difference in this respect between the two alkalies is owing to the circumstance that, while both are converted into carbonates by uniting with the carbon dioxide of the air, potassium hydroxide forms a deliquescent and sodium hydroxide an efflorescent salt. It is apt to contain 20 or 25 per cent. of water and impurities originating from the sodium carbonate used in preparing the solution from which it is made. The official volumetric assay permits the presence of 10 per cent. of water and impurities, but limits the fixed impurities to 2 per cent.

If the solution be colored brown by hydrogen or ammonium sulphide, the presence of lead may be suspected, derived probably from the glass vessels in which it has been kept. It may be used for making the solution of sodium hydroxide extemporaneously. (See *Liquor Sodii Hydroxidi.*)

Uses.—Sodium hydroxide is rarely employed as an internal remedy. Its most important medical use is as a caustic for the same class of cases in which potassium hydroxide is employed. (See page 901.) It has the advantage over the latter of being less deliquescent and is probably milder. Under the name of *London Paste* there was formerly used for the destruction of diseased tonsils in the London Throat Hospital a combination made by triturating together equal parts of caustic soda and unslaked lime.

Off. Prep.—Liquor Sodii Hydroxidi, *U. S.;* Soda cum Calce, *N. F.*

SODII HYPOPHOSPHIS. U. S., Br.

SODIUM HYPOPHOSPHITE Sod. Hypophos.

(sō'dĭ-ī hȳ-pǫ-phŏs'phĭs)

"It contains not less than 98 per cent. of $NaPH_2O_2 + H_2O$ (106.07). Preserve it in well-closed containers. Caution should be observed in dispensing Sodium Hypophosphite, as an explosion is liable to occur when it is triturated or heated with nitrates, chlorates or other oxidizing agents." *U. S.* "Sodium Hypophosphite may be obtained by the interaction of sodium carbonate and calcium hypophosphite. When dried at 110° C. (230° F.) it contains not less than

97 per cent. of pure sodium hypophosphite, $NaPH_2O_2$." *Br.*

Natrium Hypophosphorosum, Hypophosphis Sodicus; Hypophosphite of Soda; Hypophosphite de Soude, *Fr. Cod.*; Unterphosphorigsaures Natron, *G.*; Hipofosfito sodico, *Sp.*

Preparation.—*Sodium hypophosphite* is prepared by mixing solutions of calcium hypophosphite and monohydrated sodium carbonate, in the proportion of eight ounces of the former dissolved in five pints of water to six of the latter in two pints of water. Double decomposition takes place, with the formation of calcium carbonate and sodium hypophosphite, of which the latter is held in solution and the former is precipitated.

$$Ca(H_2PO_2)_2 + Na_2CO_3 = 2NaH_2PO_2 + CaCO_3$$

After filtration to separate the calcium carbonate, the solution is evaporated to a pellicle, and then stirred constantly until the salt granulates, the heat being continued. If required quite pure, the granulated salt is dissolved in official alcohol, and the liquid, having been evaporated to a syrupy consistence, is set aside to crystallize.

Sometimes sodium hypophosphite explodes with violence during the evaporation of its solution. This was ascribed to the use of too high a temperature; but the same accident has occurred when the heat was applied by means of a water bath. (See *A. J. P.*, 1860, p. 87.) In the *Chemical News* (No. 31, p. 46), Tuson stated that, though he had superintended the manufacture of large quantities of calcium and sodium hypophosphites, he had never witnessed anything like an explosion; but the heat employed in evaporation had never approached 100° C. (212° F.), and this is probably the true explanation. Caution, therefore, should be observed to evaporate at a low temperature.

Properties.—"Sodium Hypophosphite occurs as small, colorless, transparent, rectangular plates of a pearly luster, or as a white, granular powder; odorless, and having a saline taste. It is deliquescent on exposure to moist air. One Gm. of Sodium Hypophosphite dissolves in 1 mil of water at 25° C. (77° F.); also in about 0.15 mil of boiling water; soluble in alcohol, slightly soluble in dehydrated alcohol, and freely soluble in glycerin at 25° C. (77° F.); freely soluble in boiling alcohol. An aqueous solution of Sodium Hypophosphite (1 in 20) is neutral or slightly alkaline to litmus. When heated in a test tube, the salt at first loses its water of crystallization, and upon further heating is decomposed, evolving spontaneously inflammable hydrogen phosphide, which burns with a bright yellow flame. To a non-luminous flame the salt imparts an intensely yellow color. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added drop by drop with agitation to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the Solution of Sodium Hypophosphite, the precipitate becomes gray from reduction to metallic mercury. A solution of 1 Gm. of the salt in about 10 mils of distilled water requires not more than 1.5 mils of tenth-normal hydrochloric acid V.S. for neutralization, methyl orange T.S. being used as indicator. Heat 5 mils of an aqueous solution of the salt (1 in 5) in a test tube with 0.5 mil of diluted hydrochloric acid on a water bath for thirty minutes; no offensive odor is developed. Measure 5 mils of an aqueous solution of the salt (1 in 25) into a beaker containing 3 mils of nitric acid, diluted with about 10 mils of distilled water, and evaporate the mixture to dryness on a water bath; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Add magnesia mixture T.S. to 10 mils of an aqueous solution of the salt (1 in 20), made alkaline with ammonia water; it is not affected within one minute (*phosphate*).

"**Assay.**—Dissolve about 1 Gm. of Sodium Hypophosphite, accurately weighed, in 10 mils of distilled water, add 10 mils of nitric acid and evaporate the solution to dryness on a water bath. Then add 5 mils of nitric acid and again evaporate to dryness on a water bath. Dissolve the residue in 20 mils of distilled water, add a drop of phenolphthalein T.S. and sufficient special potassium hydroxide T.S. (see Reagents) to produce a pink color, and then dilute to exactly 100 mils with distilled water. Transfer 10 mils of this solution to a 100 mil graduated flask, add 50 mils of tenth-normal silver nitrate V.S. and proceed from this point as directed in the assay under *Sodii Phosphas*. It shows, in the dried salt, not less than 98 per cent. of $NaPH_2O_2 + H_2O$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.0035357 Gm. of $NaPH_2O_2 + H_2O$. Each gramme of Sodium Hypophosphite corresponds to not less than 277.2 mils of tenth-normal silver nitrate V.S." *U. S.*

"White granules, deliquescent. Taste bitter, nauseous. Soluble in 1 part of *water* and in 30 parts of *alcohol* (90 per cent.); insoluble in *ether*. Yields, when heated, spontaneously inflammable hydrogen phosphide and hydrogen. Yields the *reactions* characteristic of sodium, Rapidly attacked by oxidising agents. Its solution yields with a warm aqueous solution of *copper sulphate* a red precipitate of cuprous hydride, which on boiling evolves hydrogen. Yields no characteristic *reactions* for copper, iron, aluminium, zinc, calcium, magnesium, potassium, or ammonium, and not more than the slightest *reactions* for carbonates, chlorides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Loses not more than 2 per cent. of its weight when dried at 110° C. (230° F.). When the salt thus dried is assayed by the process described under 'Calcii Hypophosphis' not more than 28 millilitres of *N/10 solution of sodium thiosulphate* are required to decolorise the iodine liberated, corresponding to not less than 97 per cent. of pure sodium hypophosphite, $NaPH_2O_2$." *Br.*

The solubility of sodium hypophosphite is increased by the addition of hypophosphorus acid. As the soluble salts of mercury and silver are reduced by the hypophosphites, they are, of course, incompatible with sodium hypophosphite in prescriptions. With calcium hypophosphite, all the soluble sulphates and carbonates produce precipitates.

Uses.—This preparation is as useless as the other hypophosphites. (See *Syrupus Hypophosphitum Compositus.*)

Dose, ten to twenty grains (0.65–1.3 Gm.), three times a day.

F.;* Liquor Hypophosphitum Compositum, *N. F.;* Syrupus Calcii et Sodii Hypophosphitum *N. F.;* Syrupus Hypophosphitum Compositus, *N. F.;* Syrupus Sodii Hypophosphitis, *N. F.*

SODII INDIGOTINDISULPHONAS. U. S.

SODIUM INDIGOTINDISULPHONATE Sod. Indigotin. [Indigo Carmine]

(sō′dĭ-ī ĭn-dĭ-gō-tĭn-dī-sŭl′phŏ-nās)

"Chiefly the sodium salt [$C_{16}H_8O_2N_2(SO_3Na)_2 = 466.22$] of indigotindisulphonic acid." *U. S.*

Indigotin, commonly called *indigo blue,* $C_{16}H_{10}N_2O_2$, is a neutral, tasteless, dark blue powder, insoluble in water. When this is acted upon by sulphuric acid it forms disulphindigotic (sulpho-coerulic) acid, $C_{16}H_8N_2O_2(HSO_3)_2$. This acid is neutralized by sodium and the official salt is produced. This is known as indigo-carmine, soluble indigo, coeruline and other similar descriptive names.

It is officially described as follows: "Sodium Indigotindisulphonate occurs as a blue powder or as a dark purple paste. Before applying the following tests to the paste, deprive it of water by drying it to constant weight at 100° C. (212° F.). When compressed, it acquires a coppery luster. Sodium Indigotindisulphonate is sparingly soluble in water, yielding a dark blue solution; almost insoluble in alcohol. The addition of nitric acid, bromine water, or chlorine water to an aqueous solution of the salt (1 in 200) discharges the blue color. The blue color is also discharged by warming this solution with sodium hydroxide and zinc dust or with stannous chloride T.S. Dissolve 1 Gm. of Sodium Indigotindisulphonate, previously dried to constant weight at 100° C. (212° F.), in 200 mils of distilled water, filter the solution through counterbalanced filters, wash the filters and residue with distilled water until the washings cease to be colored blue, and dry at 100° C. (212° F.). The dry, insoluble residue remaining on the filter does not exceed 2 per cent. Boil about 0.2 Gm. of Sodium Indigotindisulphonate for two minutes with 10 mils of distilled water, cool, and then triturate the solution with small portions of bromine water until the blue color disappears. On now adding a few drops of potassium iodide T.S. to the liquid, no blue color is produced (*starch or starch iodide*). Add 15 mils of solution of hydrogen dioxide and 10 mils of sodium hydroxide T.S. to about 0.2 Gm. of the salt, shake the mixture until the blue color disappears, then evaporate the liquid to about 10 mils, cool, acidulate with hydrochloric acid, and add a few drops of ferrous sulphate T.S.; no blue color is produced (*iron ferricyanide or ferrocyanide*)." *U. S.*

This salt is used as a dye and also as a microscopic stain and in certain chemical reagents both for qualitative and quantitative tests. It is official for the purpose of coloring the tablets of corrosive sublimate (see *Toxitabellæ Hydrargyri Chloridi Corrosivi,* U. S.).

SODII IODIDUM. U. S., Br.

SODIUM IODIDE Sod. Iod.

(sō′dĭ-ī ī-ŏd′ĭ-dŭm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 99 per cent. of NaI (149.92). It contains not more than 7 per cent. of moisture. Preserve it in well-closed containers." *U. S.* "Sodium Iodide may be obtained from iodine and sodium hydroxide by a process similar to that employed in making Potassium Iodide, the salt being crystallised at a temperature not lower than 20° C. (68° F.). When dried at 110° C. (230° F.) it contains not less than 99 per cent. of pure sodium iodide, NaI." *Br.*

Iodure de Sodium, *Fr. Cod.;* Natrium Jodatum, *P. G.;* Natriumjodid, Jodnatrium, *G.;* Yoduro sodico, *Sp.*

Preparation.—This iodide may be prepared either by treating a solution of sodium hydroxide with iodine, or by double decomposition between ferrous iodide and sodium carbonate, precisely as potassium iodide is obtained by the corresponding processes for that salt.

Properties.—It is a very soluble white salt, crystallizing in anhydrous cubes from a hot solution, and in oblique rhombic prisms, with two molecules of water, by spontaneous evaporation. It is officially described as in "colorless, cubical crystals, or as a white, crystalline powder; odorless, and having a saline taste. In moist air Sodium Iodide deliquesces, or at first cakes and then deliquesces, and frequently undergoes decomposition, assuming a brown tint. One Gm. of Sodium Iodide dissolves in 0.55 mil of water, about 2 mils of alcohol, and in 1 mil of glycerin at 25° C. (77° F.); also in 0.4 mil of boiling water. An aqueous solution of Sodium Iodide (1 in 20) is neutral or slightly alkaline to litmus. When strongly heated, the salt melts, and at a bright red heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intensely yellow color. Add

1 mil of ferric chloride T.S., diluted with an equal volume of distilled water, to 5 mils of an aqueous solution of the salt (1 in 20); and shake the mixture with 5 mils of chloroform; the latter acquires a violet color. Dissolve 1 Gm. of the salt in 10 mils of distilled water, and add 0.15 mil of tenth-normal sulphuric acid V.S.; no red color is produced by the addition of a drop of phenolphthalein T.S. (*alkali*). A solution of 1 Gm. of the salt in 1 mil of distilled water yields no precipitate with 1 mil of sodium bitartrate T.S. (*potassium*). Dissolve 0.5 Gm. of the salt in 10 mils of distilled water, which has been previously boiled and cooled, and add 2 drops of diluted sulphuric acid (free from sulphurous or nitrous acid), no distinct, yellow color appears within half a minute (*iodate*), and no turbidity occurs (*thiosulphate*). Add 5 mils of potassium hydroxide T.S. and about 0.2 Gm. of aluminum wire to a solution of 1 Gm. of Sodium Iodide, in 5 mils of distilled water contained in a test tube of about 40 mils capacity. Insert a pledget of purified cotton in the upper portion of the test tube, and place a piece of moistened red litmus paper over its mouth. On heating the tube and contents upon a water bath for fifteen minutes, no blue coloration of the paper is discernible (*nitrate or nitrite*). Ten mils of an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is not rendered turbid by the addition of 1 mil of potassium sulphate T.S. (*barium*); another 10 mil portion of an aqueous solution (1 in 20), acidulated with hydrochloric acid, is not rendered more than slightly turbid by a few drops of barium chloride T.S. (*sulphate*). Heat gently 5 mils of an aqueous solution of the salt (1 in 10) with 1 drop of ferrous sulphate T.S., 1 drop of ferric chloride T.S., and 0.5 mil of potassium hydroxide T.S.; no blue color appears after acidulating the mixture with hydrochloric acid (*cyanide*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). When dried to constant weight at 100° C. (212° F.), it loses not more than 7 per cent. of its weight (*moisture*).

"**Assay.**—Proceed as directed under the Assay for iodides (see Part III, Test No. 5), using about 0.5 Gm. of Sodium Iodide, previously dried to constant weight at 100° C. (212° F.), and accurately weighed. It shows, in the dried salt, not less than 99 per cent. of NaI.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.014992 Gm. of NaI. Each gramme of Sodium Iodide, previously dried, corresponds to not less than 66 mils nor more than 67.7 mils of tenth-normal silver nitrate V.S." *U. S.*

"A white crystalline powder, deliquescent. Taste saline and somewhat bitter. Soluble in less than 1 part of *water* and in 3 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium and of iodides. Loses not more than 5 per cent. of its weight when dried at 110° C. (230° F.); 0.5 gramme of this dried salt requires for complete precipitation not less than 33.0 or more than 33.9 millilitres of *N/10 solution of silver nitrate*. Yields no characteristic *reactions* for copper, iron, aluminium, calcium, magnesium, potassium, ammonium, bromates, cyanides, carbonates, or iodates, and not more than the slightest *reactions* for bromides, chlorides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Sodium iodide possesses the same incompatibilities as the other soluble iodides. It produces insoluble precipitates with mercurous, lead and silver salts and even weak oxidizing agents liberate iodine from it when in solution.

Uses.—Sodium iodide has the same therapeutic effects as the other iodides. (See *Iodum.*) It is said to be better borne by the stomach than potassium iodide, although it contains 8 per cent. more iodine. Pfannenstill (*D. M. W.*, 1911, p. 2420) asserts that by the conjoint internal administration of large doses of sodium iodide and hydrogen peroxide externally, a local liberation of free iodine may be obtained at the point of application of hydrogen dioxide. He recommends this method of treatment, especially in *tuberculous ulcers* of the mucous membrane and in *lupus*. His method has received some confirmation, and Reuterskiold (*Cb. Chir.*, 1911, p. 985) has found it of service in various surgical conditions, such as *osteomyelitis, cellulitis, infected leg ulcers*, etc.

Dose, five to thirty grains (0.32–2.0 Gm.).

Off. Prep.—Syrupus Ferri et Mangani Iodidi, *N. F.*

SODII NITRIS. U. S., Br.

SODIUM NITRITE Sod. Nitris.

(sō'dĭ-ī nī'trĭs)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 95 per cent. of $NaNO_2$ (69.01). Preserve it in well-closed containers." *U. S.* "Sodium Nitrite may be obtained by fusing sodium nitrate with metallic lead. It contains not less than 95 per cent. of pure sodium nitrite, $NaNO_2$." *Br.*

Nitrite of Sodium, Nitrite of Soda; Nitrite de Soude, *Fr.*; Salpetrigsaures Natron, *G.*

Preparation.—According to M. A. Darbon, it is made on a large scale as follows: Sodium nitrate is melted in large cast iron vessels, whereby hygroscopic water is removed and a part of the iodides and iodates, still present, are decomposed. At 310° C. (590° F.) the nitrate begins to fuse. It is heated to 400° to 420° C. (752°–788° F.), and pure metallic lead in thin sheets is gradually added, the mass being constantly stirred, about 280 parts of lead being necessary for 100 parts of sodium nitrate used. The lead must be as free as possible from other metals and antimony particularly must be absent. When all the lead has been added, care having been exercised to prevent overheating, the stirring must be kept up for some time, and the melted mass is then, by means of a cast iron

ladle, run in the form of thin threads into water with constant stirring.

In this process, besides the nitrite, about 1 per cent. of sodium hydroxide is produced, which in its turn dissolves a portion of lead, and has to be removed during the subsequent purification, either by nitric acid or by lead nitrate or sulphuric acid. The crude products are a solution containing the nitrite, undecomposed saltpetre, sodium hydroxide holding lead in solution, the soluble impurities of the sodium nitrate, such as sodium chloride, etc., and a residue consisting of lead oxide, a little metallic lead, and a certain proportion of lead peroxide. The solution strained from the residue, with the washings, is diluted to about 6° to 8° B., neutralized with nitric acid as long as a precipitate is formed, separated from this precipitate, concentrated to 42° to 45° B. while warm, and then left to crystallize—the crystals requiring possibly recrystallization. The pure crystals are separated by a centrifugal machine, washed, dried and packed in cylinders of double thickness of parchment paper. (*Chem. News*, Sept. 22, 1899, 146.) A more satisfactory process as used at present is by heating sodium nitrate with quicklime and passing in a current of SO_2.

$$NaNO_3 + CaO + SO_2 = NaNO_2 + CaSO_4$$

Properties.—It is officially described as in "white, or nearly white, opaque, fused masses, or sticks, as colorless, transparent, hexagonal crystals, or as a granular powder; odorless, and having a mild, saline taste. When exposed to the air, the salt deliquesces and is gradually oxidized to sodium nitrate, and becomes unfit for use. One Gm. of Sodium Nitrite dissolves in 1.5 mils of water at 25° C. (77° F.); sparingly soluble in alcohol; very soluble in boiling water. An aqueous solution of Sodium Nitrite (1 in 10) is slightly alkaline to litmus. When heated the salt melts, and at a red heat is decomposed, yielding oxygen, nitrogen, nitrogen dioxide, and sodium oxide. To a non-luminous flame it imparts an intensely yellow color. Mix 5 mils of an aqueous solution of the salt (1 in 10) with 5 drops of potassium iodide T.S. and add 5 drops of hydrochloric acid; iodine is liberated, and nitrogen dioxide gas escapes with effervescence. Dissolve 0.5 Gm. of the salt in 25 mils of diluted hydrochloric acid, evaporate the solution to dryness and dissolve the residue in 25 mils of distilled water, adding a few drops of diluted hydrochloric acid; 10 mils of the resulting solution does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dissolve about 1 Gm. of Sodium Nitrite, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed in a stoppered weighing-bottle, in sufficient distilled water to make 100 mils, and add 10 mils of this solution, from a pipette, to a solution consisting of 50 mils of tenth-normal potassium permanganate V.S., 100 mils of distilled water and 5 mils of sulphuric acid. In adding the sodium nitrite solution, immerse the tip of the pipette beneath the surface of the permanganate mixture. Warm the liquid to 40° C. (104° F.), allow it to stand for five minutes and then titrate with tenth-normal oxalic acid V.S. It shows, in the dried salt, not less than 95 per cent. of $NaNO_2$.

"Each mil of tenth-normal potassium permanganate V.S. used corresponds to 0.0034505 Gm. of $NaNO_2$. Each gramme of Sodium Nitrite, previously dried, corresponds to not less than 275.3 mils of tenth-normal potassium permanganate V.S." *U. S.*

"A white crystalline powder, deliquescent. Taste saline. Soluble in 1.5 parts of *water*. Yields the *reactions* characteristic of sodium and nitrites. 0.1 gramme dissolved in *water* decolorises not less than 27.5 millilitres of *N/10 solution of potassium permanganate*, the solution being maintained slightly acid. Aqueous solution neutral or only slightly alkaline to *litmus;* gives no precipitate on the addition of *diluted sulphuric acid* (absence of lead). *Arsenic limit* 5 parts per million." *Br.*

Uses.—The injection of a nitrite into the circulation produces an increase in the rate of the pulse with a marked fall of blood pressure. At the same time if the dose has been sufficient there develops motor weakness and diminution of reflex activity. After toxic doses the breathing becomes rapid and often of dyspneic character, the mucous membranes of a peculiar slate color, and convulsions may occur. The acceleration of the heart rate is due to a depressant action upon the cardio-inhibitory center in the medulla. The fall of blood pressure is due to a dilatation of the arteries through a direct action upon the muscular coat of their walls. The vessels of the lungs do not share in this action, for H. C. Wood, Jr. (*J. Ex. M.*, 1911, xiv), has shown that the pulmonary artery is contracted rather than dilated. As was first shown by H. C. Wood (*Am. J. M. S.*, July, 1871), the motor weakness and diminished reflexes are the result of an action upon the spinal cord. The increased breathing is not due to any action upon the respiratory center, but is a response to the deprivation of the system for oxygen which is brought about through chemical alteration of the coloring matter of the blood. Whether the new compound formed is identical with methemoglobin, which results from the action of a number of poisons, or not is at present uncertain, but it is a so much more stable compound than oxyhemoglobin that the system is unable to obtain sufficient oxygen to maintain normal functions.

Of the various compounds which liberate the nitrite ion in the system and produce the physiological results described above, those official are amyl nitrite, glyceryl nitrate, ethyl nitrite, and sodium nitrite. The difference between the effects of these drugs is chiefly in their rapidity and duration. The influence of amyl nitrite may be perceived usually within 30 seconds after

its administration, and lasts for from 5 to 10 minutes, that of nitroglycerin being within 1 or 2 minutes, and rarely endures more than one-half hour, sodium nitrite manifests its action in from 5 to 10 minutes and lasts for about 2 hours. (See Wallace and Ringer, *J. A. M. A.*, 1909, liii, 1629.)

The most important use of sodium nitrite is for the purpose of reducing arterial pressure in threatened *apoplexy*, certain types of *chronic nephritis*, the early stages of *arterial degenerations*, and other conditions of too *high blood-pressure*. In arterio-sclerosis, after actual degenerative changes have taken place in the walls of the blood vessels, although widely employed it is incapable of much benefit because when the muscular tissue is replaced by connective tissue the drug can no longer cause dilatation of the arteries. On the other hand, in those forms of too high blood pressure in which there is no degenerative change in the walls of the vessels it is one of the most valuable drugs we possess to cause a temporary reduction. It has the great advantage over nitroglycerin in the longer duration of its effects. In convulsive disorders the nitrites are useful only for immediate effects and for this purpose the other preparations are superior to the sodium salt.

Because of its deliquescence sodium nitrite can be prescribed only in solution and should always be given well diluted, but even with the greatest care it will very often cause such marked gastric disturbance as to interdict its use.

Dose, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Spiritus Ætheris Nitrosi, *U. S.*

SODII PERBORAS. U. S.

SODIUM PERBORATE Sod. Perbor.

(sō'dĭ-ī pẹr-bō'răs)

"It contains not less than 9 per cent. of available oxygen, corresponding to about 86.5 per cent. of $NaBO_3 + 4H_2O$ (154.06). Preserve it in well-closed containers, in a cool place." *U. S.*

Sodium perborate is made by decomposing sodium peroxide with acid under a patented process.

In the presence of water, this salt undergoes decomposition with the formation of hydrogen dioxide and sodium metaborate, the resulting solution being slightly alkaline in reaction.

$$NaBO_3 + H_2O = H_2O_2 + NaBO_2$$

In the dried state, sodium perborate, if pure, is permanent in the air. Commercial varieties of sodium perborate yield from 5 per cent. to 10 per cent. of free oxygen.

"Sodium Perborate occurs as white, crystalline granules or as a powder; odorless, and having a saline taste. It is stable in cool and dry air, but is decomposed with the evolution of oxygen in warm or moist air. Sodium Perborate is soluble in water. A saturated aqueous solution of the salt is alkaline to litmus or phenolphthalein T.S. In aqueous solution the salt is decomposed into metaborate and hydrogen dioxide, the solution gradually evolving oxygen. Oxygen is evolved more rapidly if the solution is warmed. The salt imparts an intensely yellow color to a non-luminous flame. Turmeric paper, if moistened with an aqueous solution of the salt which has been acidulated with hydrochloric acid, becomes brown in color, particularly on drying; on moistening the dried test paper with ammonia water, the color is changed to greenish-black. Agitate a mixture of 1 mil of an aqueous solution of the salt (1 in 50), 1 mil of diluted sulphuric acid, a few drops of potassium dichromate T.S., and 2 mils of ether; the ether acquires a blue color. Strongly heat 0.5 Gm. of the salt in a platinum crucible, and dissolve the residue in 25 mils of distilled water with the aid of a few drops of hydrochloric acid; 10 mils of the resulting solution does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dissolve about 0.25 Gm. of the salt, accurately weighed, in a mixture of 50 mils of distilled water and 10 mils of diluted sulphuric acid and titrate the solution with tenth-normal potassium permanganate V.S. It shows not less than 9 per cent. of available oxygen.

"Each mil of tenth-normal potassium permanganate V.S. used corresponds to 0.0008 Gm. of available oxygen. Each gramme of Sodium Perborate corresponds to not less than 112.5 mils of tenth-normal potassium permanganate V.S." *U. S.*

Sodium perborate has been supplied under various trade names, as *peroxigen, peroxydol,* etc. Under the trade name of *Pergenol* has also been introduced a mixture of sodium perborate and sodium bitartrate. This is asserted to correspond to 12 per cent. of hydrogen dioxide, so that the preparation of a solution corresponding to the official solution of hydrogen dioxide requires one part of pergenol and three of water. *Perboral* is a mixture of the perboric acid and para-iodo-sulfonic acid. According to Jaubert (*B. M. J.*, 1905), *perborax* has the formula $Na_2B_4O_8 + 10H_2O$.

Uses.—Sodium perborate is used as a means of obtaining the therapeutic effects of hydrogen dioxide. According to Herbol (*D. M. W.*, 1908, p. 1092), a 2 per cent. solution of sodium perborate is equivalent in germicidal activity to an 0.4 per cent. solution of hydrogen dioxide. In *wounds* or *ulcers* it may be used in solution or as a dusting powder. For the preparation of antiseptic mouth wash it has the advantage over the solution of the dioxide of hydrogen of being alkaline instead of acid. It has also been employed in various skin diseases, especially in *acne vulgaris*. Herzfeld (*J. A. M. A.*, 1911, lvii, p. 6113) has used it not only as an antiseptic dressing in infected wounds, chronic ulcers, or diabetic gangrene, but as a hemostatic in epistaxis and other local bleedings. It may be employed either as a dusting powder or as a solution in strengths of from 2 per cent. upwards. It is rarely used internally.

Dose, one to three grains (0.065–0.2 Gm.).

SODII PHENOLSULPHONAS. U. S.

SODIUM PHENOLSULPHONATE Sod. Phenolsulph. [Sodii Sulphocarbolas, U. S. 1890, Sodium Sulphocarbolate]

(sō'dĭ-ī phē-nŏl-sŭl'phọ-năs)

"It contains not less than 83.64 per cent. nor more than 87.82 per cent. of anhydrous sodium phenolsulphonate (sodium paraphenolsulphonate), corresponding to not less than 99 per cent. of the crystallized salt [$NaC_6H_5O.SO_3 + 2H_2O = 232.14$]. Preserve it in well-closed containers." *U. S.*

Sodii Sulphocarbolas, *Br.*, *U. S.* 1890; Sodium paraphenolsulphonate; Sodium Sulphophenate; Sulfophénate de Soude, *Fr.*; Phenolsulfosaures Natrium, Phenylschwefelsaures Natron, *G.*

Sodium phenolsulphonate may be made by mixing equal parts of pure phenol and strong sulphuric acid, whereby *paraphenol sulphonic acid* (*sulphocarbolic acid*), $C_6H_4(HSO_3)OH$, is produced. The mixed liquids must be subjected to a temperature of 55° C. (131° F.) for several days, and then twenty parts of water should be added. Two parts of barium carbonate are added to the liquid, a little at a time, carefully graduating the quantity until effervescence ceases. The liquid is now allowed to stand to permit the precipitation of barium sulphate, and of any carbonate which might be present, and the liquor filtered. The solution of *barium phenolsulphonate* is decomposed by adding sodium carbonate until precipitation ceases, when the liquid is filtered from the barium carbonate, and the sodium phenolsulphonate may be obtained by evaporating the filtrate and crystallizing.

Properties.—"Sodium Phenolsulphonate occurs as colorless, transparent, rhombic prisms or crystalline granules; odorless, and having a cooling, saline, bitter taste. It is somewhat efflorescent in dry air. One Gm. of Sodium Phenolsulphonate dissolves in 4.2 mils of water, 140 mils of alcohol and in about 5 mils of glycerin at 25° C. (77° F.); also in 0.8 mil of boiling water and 13.5 mils of boiling alcohol. An aqueous solution of Sodium Phenolsulphonate (1 in 10) is neutral to litmus. When heated slightly above 100° C. (212° F.) the salt loses all of its water of crystallization and becomes white. At a higher temperature it chars, emits inflammable vapors having the odor of phenol, and finally leaves a residue consisting chiefly of sodium sulphate. To a non-luminous flame it imparts an intensely yellow color. A diluted solution of the salt (1 in 100) is rendered pale violet by ferric chloride T.S., but remains clear; barium chloride T.S. leaves the solution of the original salt clear, but if the salt is ignited, and the residue dissolved in distilled water, the same reagent produces in the filtered solution a copious, white precipitate. Add bromine T.S. to 10 mils of an aqueous solution of the salt (1 in 100); a permanent yellow color but neither turbidity nor precipitation is produced within two minutes (*phenol*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

Assay.—Dissolve about 0.25 Gm. of Sodium Phenolsulphonate, accurately weighed, in 50 mils of distilled water, add 50 mils of tenth-normal bromine V.S. and 5 mils of hydrochloric acid. Allow the mixture to stand for fifteen minutes, then add 2 Gm. of potassium iodide dissolved in 5 mils of distilled water, and subject the solution to residual titration with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 83.64 per cent. nor more than 87.82 per cent. of $NaC_6H_5O_4S$.

"Each mil of tenth-normal bromine V.S. used corresponds to 0.004903 Gm. of $NaC_6H_5O_4S$. Each gramme of Sodium Phenolsulphonate corresponds to not less than 170.6 mils nor more than 179.1 mils of tenth-normal bromine V.S." *U. S.*

Uses.—The phenol sulphonates, or sulphocarbolates as they are commonly called, were introduced into medicine with the idea of obtaining the antiseptic action of carbolic acid in a non-toxic form, for it is well known that the combination of sulphuric acid with phenol destroys its toxicity. But it has been shown by Withers that the phenol sulphonates are not possessed of any antiseptic power. The claim which has been made that they are decomposed in the intestinal tract with the liberation of phenol is not supported by any scientific evidence and seems *a priori* improbable. There is neither sufficient clinical nor scientific evidence of the value of this drug in medicine. Sodium phenolsulphonate is, however, still employed as an intestinal antiseptic.

Dose, five to ten grains (0.32–0.65 Gm.).

SODII PHOSPHAS. U. S., Br.

SODIUM PHOSPHATE Sod. Phos. [Sodium Orthophosphate]

(sō'dĭ-ī phŏs'phăs)

"It contains not less than 39.25 per cent. nor more than 44.00 per cent. of anhydrous sodium phosphate (di-sodium-ortho-phosphate), corresponding to not less than 99 per cent. of the crystallized salt [$Na_2HPO_4 + 12H_2O = 358.24$]. Preserve it in well-closed containers, in a cool place." *U. S.* "Sodium Phosphate may be obtained by the interaction of sodium carbonate and the solution of acid calcium phosphate produced on mixing bone-ash and sulphuric acid. It contains not less than 99.5 per cent. of pure di-sodium hydrogen phosphate, $Na_2HPO_4,12H_2O$." *Br.*

Medicinal Tribasic Sodium Phosphate, Phosphate of Soda; Disodium Hydrogen Phosphate; Phosphas Sodicus (Natricus) Sal Mirabile Perlatum; Phosphate de Soude, *Fr. Cod.*; Natrium Phosphoricum, *P. G.*; Natriumphosphat, Phosphorsaures Natron, *G.*; Fosfato bisodico, *It.*; Fosfato sodico, *Sp.*

A process for this salt is no longer official; for that of the U. S. P., 1870, see *U. S. Disp.*, 19th edition, page 1151.

The incombustible part of bones is obtained by burning them to whiteness, and consists of neutral calcium phosphate, called bone phosphate, associated with some calcium carbonate, etc. When this is mixed with sulphuric acid,

the calcium carbonate is entirely decomposed, giving rise to effervescence. The calcium phosphate undergoes partial decomposition; the greater part of the lime, being detached, precipitates as calcium sulphate, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains in solution as an acid calcium phosphate, holding dissolved a small portion of the calcium sulphate. In order to separate the acid phosphate from the precipitated mass of calcium sulphate, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as acid phosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of acid calcium phosphate, are mixed and allowed to stand, and by cooling a portion of calcium sulphate is deposited, which is removed by decantation. The bulk of the liquid is now reduced by evaporation, and, in consequence of the diminution of the water, a fresh portion of calcium sulphate is deposited, which is separated by subsidence and decantation as before. The acid calcium phosphate solution, being heated, is now saturated by means of a hot solution of sodium carbonate. The calcium carbonate is separated by a new filtration, and the filtered liquor, which is a solution of sodium phosphate, is evaporated so as to crystallize.

The reactions are as follows:

$$Ca_3(PO_4)_2 + 2H_2SO_4 = 2CaSO_4 + Ca(H_2PO_4)_2$$

$$Ca(H_2PO_4)_2 + 2Na_2CO_3 = 2Na_2HPO_4 + Ca CO_3 + CO_2 + H_2O$$

In the U. S. process of 1870 the calcined bone is to the acid as 10 to 6; in the Br. process of 1867 as 10 to 6½ nearly. The proportion recommended by Berzelius is as 10 to 6.66. The acid, in the former official process, was added to the calcined bone in the concentrated state, and afterwards diluted with more or less water. In the process given by Berzelius it is first diluted with twelve times its weight of water. All the writers state that sodium phosphate crystallizes more readily by allowing its solution to be slightly alkaline, and a remarkable fact is, that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is necessary, after getting each successive crop of crystals, to render the mother water slightly alkaline, before it will furnish an additional quantity.

Funcke, a German chemist, has given the following cheap and expeditious method for obtaining sodium phosphate. To the powdered calcined bone, diffused in water, sufficient diluted sulphuric acid is added to decompose all the calcium carbonate which it contains. When the effervescence ceases, the matter is treated with nitric acid, which dissolves the calcium phosphate and leaves the sulphate. The nitric solution of the phosphate is then treated with sodium sulphate, equal in quantity to the bone employed, and after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, calcium sulphate and sodium phosphate are formed, the latter of which is separated by water, and crystallized in the usual manner.

Properties.—The medicinal sodium phosphate, according to the U. S. Pharmacopœia IX is in "large, colorless, monoclinic prisms, or as a granular, crystalline salt; odorless, and having a cooling, saline taste. The crystals effloresce in the air. One Gm. of Sodium Phosphate dissolves in 2.7 mils of water at 25° C. (77° F.); insoluble in alcohol. An aqueous solution of Sodium Phosphate (1 in 10) is alkaline to litmus and phenolphthalein T.S. When heated to about 40° C. (104° F.) the salt fuses, yielding a colorless liquid; at 100° C. (212° F.) it loses all of its water of crystallization and at a red heat is converted into sodium pyrophosphate. It imparts an intensely yellow color to a non-luminous flame. An aqueous solution of the salt (1 in 20) yields a white, crystalline precipitate with magnesia mixture T.S. Not more than a slight turbidity appears on dissolving 1 Gm. of the salt in 20 mils of distilled water (*calcium or aluminum*). No effervescence occurs on the addition of hydrochloric or nitric acid to a solution of the salt (*carbonate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1). Add a few drops of silver nitrate T.S. to 10 mils of an aqueous solution of the salt (1 in 20), previously mixed with 5 mils of diluted nitric acid; not more than an opalescence is produced (*chloride*)." *U. S.*

"Transparent, colorless, rhombic prisms, efflorescent. Taste saline. Soluble in 7 parts of *water*, the solution being slightly alkaline to *litmus*. Yields the *reactions* characteristic of sodium and of phosphates. 5 grammes dissolved in 50 millilitres of *water* require for neutralisation not less than 13.9 millilitres of *N/1 solution of sulphuric acid, solution of methyl orange* being used as indicator. Yields no characteristic *reactions* for potassium, ammonium, carbonates, or chlorides, and not more than the slightest *reaction* for sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million." *Br.*

"Assay.—Introduce about 0.4 Gm. of Sodium Phosphate, accurately weighed, into a 100 mil graduated flask, dissolve it in 10 mils of distilled water, add 50 mils of tenth-normal silver nitrate V.S. and agitate the mixture well. Then gradually add zinc oxide (see page 1692) in small portions until the liquid is neutral to litmus. Then add distilled water to make 100 mils, agitate the mixture thoroughly, filter through a dry filter, rejecting the first 20 mils of filtrate, collect 50 mils of the subsequent filtrate, add 2 mils of nitric acid and 2 mils of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium sulphocyanate V.S. to

the production of a permanent red color. It shows not less than 39.25 per cent. nor more than 44 per cent. of Na_2HPO_4.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.004735 Gm. of Na_2HPO_4. Each gramme of Sodium Phosphate corresponds to not less than 82.9 mils nor more than 92.9 mils of tenth-normal silver nitrate V.S." *U. S.*

Before the blowpipe, sodium phosphate at first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is liable to adulteration, sometimes containing sodium carbonate, from this salt having been added in excess in its preparation, in which case it will effervesce with acids. If it contain sodium sulphate, or any other soluble sulphate, the precipitate caused by barium chloride will be a mixture of barium sulphate and phosphate, and will not be totally soluble in nitric acid. A. B. Lyons found a specimen which consisted almost entirely of sodium sulphate. (*A. J. P.*, 1875, 371; see also *N. R.*, April, 1877.) Barium chloride will detect sodium carbonate also, by producing a precipitate of barium carbonate, soluble with effervescence in nitric acid. If a chloride be present, the *yellow* precipitate caused by silver nitrate will be a mixed one of silver chloride and phosphate, not entirely soluble in the same acid. The salt is incompatible with soluble salts of lime, with which it gives a precipitate of calcium phosphate, and with neutral metallic solutions. It is found in several of the animal secretions, particularly the urine. For an elaborate article upon the methods of determining the percentage of phosphates present in a substance, see *Chem. News*, Oct., 1874, 200. Samples of sodium phosphate have been found in commerce contaminated with arsenic in dangerous quantities. The official test to detect arsenic should always be applied to sodium phosphate. (*C. D.*, June 30, 1900, 1073; *Am. Drug.*, Aug. 27, 1900, 103.)

The medicinal sodium phosphate is one of the three sodium salts of tribasic phosphoric acid, H_3PO_4. In this salt two of the three replaceable hydrogen atoms have been replaced by sodium, so that its formula is HNa_2PO_4, which then crystallizes out with 12 molecules of water. Its complete formula is then $HNa_2PO_4 + 12H_2O$. When gently heated, it loses its water of crystallization (see *Sodii Phosphas Exsiccatus*) and at a red heat the salt is converted into *sodium pyrophosphate*, $Na_4P_2O_7$. (See *Sodii Pyrophosphas.*)

Uses.—Sodium phosphate was introduced into practice about the year 1800 by Pearson of London. In doses of from one to two ounces (31 to 62 Gm.) it is a mild purgative, and, from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. In smaller doses it has been considerably used, generally in connection with other phosphates, to meet any real or supposed deficiency of phosphates in the system, and for this purpose it is well adapted by its ready solubility. It is widely believed that it exerts, especially in children, an extraordinary influence upon the hepatic secretion. It is therefore employed in *constipation* where the stools are light in color, in infantile *diarrhea*, with *white or green stools*, and sometimes with *jaundice*, these evidences of deficient or disordered bile are said to quickly yield to small doses of sodium phosphate, the passages assuming their healthy yellow color, and the attendant disease generally disappearing. It probably, however, possesses only the virtues of the other saline laxatives.

Dose, as a laxative from one to four drachms (3.9–15.5 Gm.); as a hepatic stimulant from twenty to forty grains (1.3–2.6 Gm.) may be given, dissolved in water, after meals.

Off. Prep.—Sodii Phosphas Effervescens (from Dried Salt), *U. S., Br.;* Sodii Phosphas Exsiccatus, *U. S.;* Liquor Sodii Phosphatis Compositus, *N. F.*

SODII PHOSPHAS ACIDUS. Br.

ACID SODIUM PHOSPHATE

(sō'dĭ-ī phŏs'phās ă'cĭ-dŭs)

"Acid Sodium Phosphate may be obtained by the combination of di-sodium hydrogen phosphate with phosphoric acid. It contains not less than 70 per cent. of pure sodium di-hydrogen phosphate, NaH_2PO_4." *Br.*

Sodium Di-hydrogen Phosphate: Sodium Biphosphate: Monsodium Hydrogen Phosphate.

This salt which has been introduced into medicine and is found as a commercial article, is sometimes known as *primary sodium phosphate* or *monosodium orthophosphate*. It is prepared by adding the proper molecular proportions of the ordinary disodium orthophosphate and phosphoric acid according to the following reaction:

$$Na_2HPO_4 + H_3PO_4 = 2NaH_2PO_4.$$

This salt is not only used in medicine, but is employed in the manufacture of baking powders in which it plays the part of the acidic element in liberating CO_2 from $NaHCO_3$.

It is described in the British Pharmacopœia, 1914, as "transparent, colorless, rhombic crystals, or in crystalline powder. Taste saline, acid. Readily soluble in *water*, the solution being acid to *litmus*. Yields the *reactions* characteristic of sodium and of phosphates. 1 gramme dissolved in a mixture of 10 millilitres of *water* and 10 millilitres of *glycerin* requires for neutralisation not less than 5.8 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields no characteristic *reactions* for potassium and ammonium, and not more than the slightest *reactions* for sulphates or chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million." *Br.*

Uses.—The acid sodium phosphate is used in medicine for the purpose of increasing the acidity of the urine, especially in certain types

of *cystitis*. It may be prepared extemporaneously by treating the neutral phosphate with phosphoric acid; to prepare it extemporaneously about 32 parts of the official phosphoric acid is required for each 100 parts of the official neutral sodium phosphate in solution.

Dose, from fifteen to thirty grains (1–2 Gm.) repeated as often as may be necessary.

SODII PHOSPHAS EFFERVESCENS. U. S., Br.

EFFERVESCENT SODIUM PHOSPHATE Sod. Phos. Eff.

(sō′dĭ-ī phŏs′phăs ĕf-fẹr-vĕs′cẹnṣ)

Sodæ Phosphas Effervescens; Effervescent Phosphate of Soda; Natrium Phosphoricum Effervescens; Phosphate de Soude effervescent, *Fr.*; Brausendes Natriumphosphat, *G.*

* "Exsiccated Sodium Phosphate, in fine powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Sodium Bicarbonate, dried and powdered, *four hundred and seventy-seven grammes* [or 16 ounces av., 361 grains]; Tartaric Acid, dried and powdered, *two hundred and fifty-two grammes* [or 8 ounces av., 389 grains]; Citric Acid, unefflouresced crystals, *one hundred and sixty-two grammes* [or 5 ounces av., 313 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Powder the Citric Acid and mix it intimately with the exsiccated sodium phosphate and tartaric acid, then thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). Manipulate the mixture carefully with a wooden spatula, and, when it has become moist, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Immediately transfer the salt to suitable containers and seal them tightly. Care must be taken to prevent the salt from coming in contact with air containing moisture." *U. S.*

"Sodium Phosphate, in crystals, 500 *grammes;* Sodium Bicarbonate, in powder, 500 *grammes;* Tartaric Acid, in powder, 270 *grammes;* Citric Acid, in powder, 180 *grammes.* Dry the Sodium Phosphate until it has lost about 60 per cent. of its weight; powder the dried salt and mix it with the other ingredients. Place the whole in a dish or pan of suitable form heated to between 90° and 105° C. (194° and 221° F.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. (131° F.). The product weighs about one thousand grammes." *Br.*

This salt, introduced in the Br. Add. 1885, and into the U. S. P. VIII and IX, affords a pleasant means of giving sodium phosphate.

Dose, one-fourth to one-half ounce (7.7–15.5 Gm.).

SODII PHOSPHAS EXSICCATUS. U. S.

EXSICCATED SODIUM PHOSPHATE Sod. Phos. Exsic.

(sō′dĭ-ī phŏs′phăs ĕx-sịc-cā′tŭs)

"It contains, when dried to constant weight at 110° C. (230° F.), not less than 98 per cent. of Na_2HPO_4 (142.05). Preserve it in well-closed containers." *U. S.*

* "Sodium Phosphate, *a convenient quantity.* Allow the crystals to effloresce for several days in warm air, at a temperature of from 25° to 30° C. (77°–86° F.), then continue the drying in an oven, raising the temperature very gradually until 100° C. (212° F.) has been reached, and maintaining this temperature until the salt ceases to lose weight. Powder and sift the residue and transfer it to well-closed containers." *U. S.*

Properties.—"Exsiccated Sodium Phosphate is a white powder which absorbs moisture readily, and which, after allowance is made for the loss of water of crystallization, conforms to the reactions and tests under *Sodii Phosphas.* One Gm. of Exsiccated Sodium Phosphate dissolves in 8.1 mils of water at 25° C. (77° F.); also in 1.1 mils of boiling water; insoluble in alcohol.

Assay.—Exsiccated Sodium Phosphate, when quantitatively estimated by the assay method under *Sodii Phosphas,* using about 0.15 Gm. of the salt, previously dried to constant weight at 110° C. (230° F.) and accurately weighed, shows, in the dried salt, not less than 98 per cent. of Na_2HPO_4.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.004735 Gm. of Na_2HPO_4. Each gramme of Exsiccated Sodium Phosphate, previously dried, corresponds to not less than 207 mils of tenth-normal silver nitrate V.S." *U. S.*

Uses.—This salt was introduced in this form for use in making effervescent sodium phosphate. Forty parts of exsiccated sodium phosphate represent about 100 parts of crystallized sodium phosphate (see *Sodii Phosphas*), although in damp atmosphere it absorbs water readily and may contain from 10 to 25 per cent. The water content should always be determined before it is used in any important preparation. It is not used medicinally unless in combination.

Off. Prep.—Sodii Phosphas Effervescens, *U. S.*

SODII SALICYLAS. U. S., Br.

SODIUM SALICYLATE Sod. Salicyl.

(sō′dĭ-ī săl-ị-cȳ′lăs)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 99.5 per cent. of $NaC_7H_5O_3$ (160.04). Preserve it in well-closed containers, protected from heat and light." *U. S.* "Sodium Salicylate may be obtained by the interaction of salicylic acid and sodium carbonate. It contains not less than 99.5

per cent. of pure sodium salicylate, $NaC_7H_5O_3$." *Br.*

Salicylate of Soda; Salicylate de Soude, *Fr. Cod.;* Natrium salicylicum, *P. G.;* Natriumsalicylat, *G.;* Salicilato di sodio, *It.;* Salicilato sodico, *Sp.*

This salt is prepared by mixing 100 parts of pure salicylic acid with sufficient water to form a paste, and then with 104 parts of pure crystallized sodium carbonate (U. S. P. 1890) (uneffloresced) in a glass or porcelain vessel; carbon dioxide will be evolved, and sodium salicylate will remain in solution. The liquid may be strained through thoroughly washed muslin, if necessary, and heated in an evaporating dish until the carbon dioxide is expelled. If alkaline to litmus paper, enough salicylic acid must be added to be slightly in excess, and the solution is then evaporated at a low heat to dryness. If the acid be not in excess, the salt will not be white, but gray or lead-colored.

Properties.—Pure sodium salicylate is a "white, micro-crystalline powder, or in scales, or as an amorphous powder; colorless or having not more than a faint pink tinge; odorless, or having a faint, characteristic odor and a sweet, saline taste. One Gm. of Sodium Salicylate dissolves in 0.9 mil of water and in 9.2 mils of alcohol at 25° C. (77° F.); very soluble in boiling water or in boiling alcohol; soluble in glycerin. An aqueous solution of Sodium Salicylate (1 in 10) when freshly made is colorless or nearly colorless, and neutral or slightly acid to litmus. When heated the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a residue of sodium carbonate and carbon. To a non-luminous flame it imparts an intensely yellow color. Add a few drops of ferric chloride T.S. to an excess of a concentrated aqueous solution of Sodium Salicylate (1 in 4); a dark red color and a precipitate are produced. In a solution of the salt (1 in 100) a deep violet-blue color is produced. Diluted hydrochloric acid or sulphuric acid produces a voluminous, white precipitate in a concentrated aqueous solution of the salt. Add 1 mil of hydrochloric acid to a solution of 1 Gm. of Sodium Salicylate in 20 mils of distilled water and filter the liquid; the filtrate does not decolorize 2 drops of tenth-normal iodine V.S. (*sulphite or thiosulphate*). Add a slight excess of hydrochloric acid to an aqueous solution of the salt (1 in 50), and filter; the filtrate does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6), using about 2 Gm. of Sodium Salicylate, previously dried to constant weight at 100° C. (212° F.) and accurately weighed. It shows, in the dried salt, not less than 99.5 per cent. of $NaC_7H_5O_3$.

"Each mil of half-normal sulphuric acid V.S. used corresponds to 0.08002 Gm. of $NaC_7H_5O_3$. Each gramme of Sodium Salicylate, previously dried, corresponds to not less than 12.43 mils of half-normal sulphuric acid V.S." *U. S.*

"Small colorless scales, or tabular crystals with a pearly lustre. No odor; taste sweetish, unpleasant, saline. Soluble in 1 part of *water*, but this solution, when allowed to stand, is liable to deposit crystals of the salt containing 6 molecules of water of crystallisation; soluble in 6 parts of *alcohol* (90 per cent.). Solutions neutral or faintly acid to *litmus*. Carbonises when heated, leaving finally a white ash which effervesces with acids and imparts an intense yellow color to flame. *T. Sol. of ferric chloride* colors a dilute solution violet. 2 grammes, heated to redness till gases cease to be evolved, leave an alkaline residue which, when treated with *water*, filtered, and well washed, yields a clear solution requiring for neutralisation not less than 24.8 millilitres of *N/2 solution of sulphuric acid.* When to a concentrated aqueous solution excess of *diluted nitric acid* is added, a precipitate is produced which, collected, washed, and dried, responds to the tests described under 'Acidum Salicylicum,' and the filtrate yields not more than the slightest *reactions* for sulphates or chlorides. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million. 50 to 100 grammes kept in a closed vessel for several days do not evolve the slightest odor of phenol. Dissolves without coloration or effervescence in *sulphuric acid* (absence of certain organic impurities and of carbonates)." *Br.*

Sodium salicylate is incompatible with antipyrine, forming, when mixed in powder, a liquid mixture.

Uses.—The action of sodium salicylate upon the economy, and its therapeutic use, are precisely those of salicylic acid, except that the salt is not locally irritating, and, being soluble, is more rapidly absorbed. When salicylic acid is administered, it is mostly converted into sodium salicylate before it is absorbed into the blood. One drachm of the salt contains about fifty grains of the acid.

Dose, from ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Caffeinæ Sodio-Salicylas, *N. F.;* Elixir Sodii Salicylatis, *N. F.;* Elixir Sodii Salicylatis Compositum, *N. F.;* Liquor Antisepticus, *N. F.;* Liquor Ferri Salicylatis, *N. F.*

SODII SULPHAS. U. S., Br.

SODIUM SULPHATE Sod. Sulph. [Glauber's Salt]

(sō'dĭ-ī sŭl'phăs)

"It contains not less than 43.64 per cent. nor more than 48 per cent. of anhydrous sodium sulphate, corresponding to not less than 99 per cent. of the crystallized salt [$Na_2SO_4 + 10H_2O = 322.23$]. Preserve it in well-closed containers, in a cool place." *U. S.* "Sodium Sulphate, $Na_2SO_4,10H_2O$, may be obtained by the interaction of sodium chloride with sulphuric acid," *Br.*

Sulphate of Soda; Sulfas Sodicus (Natricus), Sal mirabile Glauberi; Vitriolated Soda, Glauber's Salt; Sulfate de Soude purifié, *Fr. Cod.;* Sel de Glauber, *Fr.;* Natrium Sulfuricum, *P. G.;* Natriumsulfat, Schwefelsaures Natron, Glaubersalz, *G.;* Solfato di Sodio, *It.;* Sulfato Sodico, Sal admirabile de Glaubero, *Sp.*

Sodium sulphate, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad, and it is found combined with calcium sulphate constituting a distinct mineral. Many ponds containing this salt are found in the country between Santa Fé and the head waters of the Arkansas, and on the route to the Rocky Mountains. Sodium Sulphate occurs in abundant deposits, in conjunction with sodium carbonate, in Wyoming. As an artificial product, sodium sulphate is formed in the processes for obtaining hydrochloric acid and chlorine, and in the preparation of ammonium chloride from ammonium sulphate and common salt. It may also be procured from sea water, in which it is present.

Immense quantities of sodium sulphate are made by decomposing common salt by sulphuric acid, in the manufacture of soda-ash and sodium carbonate (see *Sodii Carbonas*), in both the Leblanc and the Hargreave's processes. So far from the generated hydrochloric acid being a product of much value, its absorption in a convenient way, so as to avoid the nuisance of its escape into the atmosphere in a gaseous state, is an object of importance to the manufacturer. (See *Acidum Hydrochloricum.*) At Strassfurt sodium sulphate is produced extensively by utilizing the mother liquors from the treatment of carnallite or kilderite, which still contains about 25 per cent. of magnesium sulphate and 50 per cent. of sodium chloride.

The residue of the process for obtaining chlorine by the action of sulphuric acid and manganese dioxide on common salt is a mixture of sodium sulphate and manganous sulphate. Large quantities of this residue are formed in manufacturing chlorinated lime (bleaching powder), and the sodium sulphate in it, roughly purified, supplies a part of the salt consumed in making soda-ash and sodium carbonate.

The process for obtaining ammonium chloride from ammonium sulphate and common salt forms another source of sodium sulphate. By double decomposition, sodium sulphate and ammonium chloride are formed, and by exposing the mixed salts to heat, the ammonium chloride sublimes, and the sodium sulphate remains behind. (See *Ammonii Chloridum.*)

Properties.—Sodium sulphate is in "large, colorless, transparent, monoclinic prisms, or granular crystals; odorless, and having a bitter, saline taste. The salt effloresces rapidly in the air. One Gm. of Sodium Sulphate dissolves in slightly over 1 mil of water at 25° C. (77° F.); insoluble in alcohol; soluble in glycerin; when heated to about 33° C. (91.4° F.) it melts in its water of crystallization. An aqueous solution of the salt (1 in 10) is neutral to litmus. When gently heated the salt fuses, and, on continuing the heat to 100° C. (212° F.), it loses all of its water of crystallization (about 56 per cent.). At a red heat, the anhydrous salt fuses without decomposition. To a non-luminous flame it imparts an intensely yellow color. An aqueous solution of Sodium Sulphate (1 in 20) yields with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Dissolve about 1 Gm. of Sodium Sulphate, accurately weighed, in 100 mils of distilled water, acidulate the solution with hydrochloric acid and heat it to boiling. Gradually add an excess of hot barium chloride T.S., heat for thirty minutes on a water bath, collect the precipitate of barium sulphate on a filter, wash it until silver nitrate T.S. no longer produces an opalescence in 2 mils of the filtrate acidulated with nitric acid, dry, ignite, and weigh it. It corresponds to not less than 43.64 per cent. nor more than 48 per cent. of Na_2SO_4.

"Each gramme of Sodium Sulphate corresponds to not less than 0.717 Gm. nor more than 0.789 Gm. of $BaSO_4$." *U. S.*

"In transparent monoclinic prisms; efflorescent. Taste bitter, saline. Soluble in 3 parts of *water;* insoluble in *alcohol* (90 per cent.). Loses about 55.9 per cent. of its weight when dried at 100° C. (212° F.). Yields the *reactions* characteristic of sodium and of sulphates. 1 gramme dissolved in *water* acidified with *hydrochloric acid* yields, on the addition of excess of *solution of barium chloride,* a white precipitate which, washed and dried, weighs about 0.724 gramme. Yields no characteristic *reactions* for iron, magnesium, potassium, ammonium, or carbonates, and not more than the slightest *reactions* for chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million." *Br.*

When recently prepared it is beautifully transparent; but on exposure to the air it effloresces, and the crystals become covered with an opaque white powder. After long exposures it undergoes complete efflorescence, and falls into powder with loss of more than half its weight. A supersaturated solution of sodium sulphate will remain without crystallizing at ordinary temperatures, even though containing several times the weight of the salt that will be dissolved at the same degree of heat. But the solution instantly forms into a crystalline mass upon adding to it a fragment of the same salt crystallized, or other substances that have been exposed to the air, or upon abruptly placing it in contact with the air.

When crystallized sodium sulphate is subjected to heat it dissolves in its water of crystallization, then dries, and afterwards by the application of a red heat melts with the loss of 55½ per cent. of its weight. Coppet has ascertained that there are two varieties of the anhydrous sulphate—one in which the salt is deprived of its water at ordinary temperature, the other in which the desiccation is effected at a heat above that of 33° C. (91.4° F.). The two differ in their relation to the crystalliza-

tion of the salt, the former causing immediate crystallization when thrown into a supersaturated solution, the second not. Occasionally it contains an excess of acid or alkali, which may be discovered by litmus or turmeric paper. Common salt may be detected by silver nitrate; a salt of iron by potassium ferrocyanide. This salt is not subject to adulteration. It is incompatible with potassium carbonate, calcium chloride, the salts of barium, lead acetate and subacetate, and with silver nitrate if the solutions are strong. It consists of two atoms of sodium combined with the group SO_4 characteristic of sulphates, and crystallizes with ten molecules of water, $Na_2SO_4 + 10H_2O$.

Uses.—Sodium sulphate in doses of from half an ounce to an ounce (15.5–31 Gm.) is an efficient hydragogue cathartic; in smaller doses, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half, on account of its having lost about one-half of its weight of water. Sodium sulphate is much less used than formerly, having been almost entirely superseded by magnesium sulphate, which is less disagreeable to take and milder in its action. Its nauseous taste, however, may be disguised by the admixture of a little lemon juice or cream of tartar, or by the addition of a few drops of sulphuric acid. It is an ingredient in the artificial Cheltenham salt. (See Part II.) D. de Luca has found sodium sulphate remarkably efficient in removing *stains* or *opacity* of the *cornea,* if applied in the form of powdered crystals directly to the eyeball twice daily. (*J. P. C.,* Sept., 1867.) The only uses of sodium sulphate in the arts are to make sodium carbonate and some kinds of glass. It has no U. S. official preparations.

Dose, two drachms to an ounce (7.7–31 Gm.).

Off. Prep.—Sodii Sulphas Effervescens, *Br.;* Sal Carolinum Factitium, *N. F.;* Sal Carolinum Factitium Effervescens, *N. F.*

SODII SULPHAS EFFERVESCENS. Br.

EFFERVESCENT SODIUM SULPHATE

(sō′dĭ-ī sŭl′phăs ĕf-fẹr-vĕs′cẹns)

Sodæ Sulphas Effervescens; Effervescent Sulphate of Soda; Natrium Sulfuricum Effervescens; Brausendes Natriumsulfat, *G.*

"Sodium Sulphate, in crystals, 500 *grammes;* Sodium Bicarbonate, in powder, 500 *grammes;* Tartaric Acid, in powder, 270 *grammes;* Citric Acid, in powder, 180 *grammes.* Dry the Sodium Sulphate until it has lost about 55 per cent. of its weight; powder the dried salt, and mix it with the other ingredients. Place the whole in a dish or pan of suitable form, heated to between 90° and 105° C. (194° and 221° F.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. (131° F.). The product weighs about one thousand grammes." *Br.*

It is used as an effervescent laxative, in the *dose* of from one-fourth to one-half ounce (7.7–15.5 Gm.) dissolved in cold water and taken while effervescing.

SODII SULPHIS. Br.

SODIUM SULPHITE

(sō′dĭ-ī sŭl′phĭs)

"Sodium Sulphite may be obtained by the interaction of sulphurous acid and sodium carbonate. It contains not less than 94 per cent. of pure sodium sulphite, $Na_2SO_3,7H_2O$." *Br.*

Natrium Sulfurosum, Sulfis Sodicus (Natricus); Sulfite de Soude, *Fr.;* Natriumsulfit, Schwefligsaures Natron, *G.*

This salt may be prepared by passing sulphurous acid gas into a solution of sodium carbonate, and evaporating out of contact of the air. The sulphurous acid unites with the soda of the carbonate to form sodium sulphite, and the carbon dioxide escapes. After sufficient concentration, the solution is allowed to cool, and the salt crystallizes. A better way, however, is to dissolve a convenient weight of sodium carbonate in a small quantity of water, then pass the sulphurous acid gas through the solution until it is completely saturated, and acid sodium sulphite is formed. The addition of an equal weight of sodium carbonate forms a solution of the neutral sulphite, which is to be evaporated and crystallized. On exposure the salt gradually changes into a sulphate.

Sulphuric acid added to the solution gives rise to an odor of burning sulphur, owing to the escape of sulphurous acid, and the liquid remains transparent, indicating the absence of calcium. Sodium sulphite consists of two atoms of sodium combined with the group SO_3, characteristic of sulphites, and crystallized with seven molecules of water, $Na_2SO_3 + 7H_2O$. For methods of determining sodium carbonate in sodium sulphite by C. E. Caspari and M. R. Moffat the reader is referred to *Proc. A. Ph. A.,* 1902; also *West. Drug.,* 1904, 59. Sodium sulphite has been replaced in the U. S. P. by the more stable exsiccated salt, which see.

Properties.—"Colorless, transparent, monoclinic prisms, efflorescent in dry air. Inodorous; taste saline and sulphurous. Soluble in 2 parts of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium and of sulphites. Aqueous solution neutral or faintly alkaline to *litmus;* on the addition of *hydrochloric acid* evolves sulphur dioxide, but does not become cloudy (absence of thiosulphate). 0.3 gramme dissolved in 30 millilitres of *N/10 solution of iodine* yields a solution which requires for complete decolorisation not more than 7.6 millilitres of *N/10 solution of sodium thiosulphate. Arsenic limit* 5 parts per million." *Br.*

Uses.—According to the experiments of L. Pfeiffer (*A. E. P. P.,* xxvii), the sulphites are capable of causing death by paralyzing the heart and also the respiratory and other motor

nerve centers, but are so rapidly and completely changed into the sulphates that unless given in enormous amount they exert very little influence upon the system; 96.5 per cent. of the sulphite was regained from the urine as a sulphate, and 86 per cent. passed out in five hours after ingestion. But according to Kionka (*D. M. W.*, 1902, xxviii, p. 89) even in doses comparable to those used in the preservation of food the prolonged use produced in dogs serious symptoms of intoxication. Although the experiments of Sternberg have demonstrated that sodium sulphite has no germicidal powers, it appears to be distinctly toxic to the more highly organized fungoid parasites. It has been used in cases of *yeasty vomiting* with remarkable success. The matter vomited in these cases contains two microscopic fungi, called Sarcina ventriculi and Torula cerevisiæ. The remedy was first used at the suggestion of Graham of London, who supposed that the sulphurous acid, necessarily extricated from the salt in the stomach by the acid of the yeasty matter, would destroy the parasites. Sodium sulphite is sometimes used locally, especially in that species of *aphthous sore mouth* which is attributed to a parasitic vegetable. The wash may be made of a drachm of the salt to a fluidounce of water. It is said that the solution acts with surprising rapidity, a single application of it sometimes removing the disease in 24 hours. Astrié, an Italian physician, has proposed this salt as a remedy for the constitutional effects of mercury, when used in excess, on the ground that it has the power of rendering the metal soluble. It also has been largely given internally as an antizymotic (see *Sodii Thiosulphas*), but without general success.

Dose, of sodium sulphite, fifteen to sixty grains (1.0–3.9 Gm.).

SODII SULPHIS EXSICCATUS. U. S.

EXSICCATED SODIUM SULPHITE Sod. Sulphis. Exsic.

(sō′dĭ-ī sŭl′phĭs ĕx-sĭc-cā′tŭs)

"It contains not less than 90 per cent. of Na_2SO_3 (126.07). Preserve it in well-closed containers, in a cool place." *U. S.*

This salt may be readily prepared from the crystallized salt by heating the latter at a temperature slightly above 100° C. (212° F.) until an anhydrous residue of constant weight remains. It is more uniform in water content than the crystalline salt, which was official in the U. S. P. VIII.

It is officially described as follows: "Exsiccated Sodium Sulphite occurs as a white powder; odorless, and having a cooling, saline, sulphurous taste. Exposed to the air, it is slowly oxidized to sulphate. One Gm. of Sodium Sulphite dissolves in 3.2 mils of water at 25° C. (77° F.); sparingly soluble in alcohol. An aqueous solution of the salt (1 in 10) is alkaline to litmus. At a red heat, the salt fuses to a reddish-yellow mass of sodium sulphate and sodium sulphide. To a non-luminous flame the salt imparts an intensely yellow color. Upon the addition of hydrochloric acid to the salt, sulphur dioxide is liberated, which is recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the escaping gas. Dissolve 1 Gm. of Exsiccated Sodium Sulphite in 10 mils of diluted hydrochloric acid and heat the solution sufficiently to expel the gases; the liquid does not become turbid (*thiosulphate*). Dissolve 1 Gm. of the salt in 20 mils of diluted hydrochloric acid, evaporate the solution to dryness, and dissolve the residue in 50 mils of distilled water. Ten mils of this solution does not respond to the Test for heavy metals (see Part III, Test No. 3). Add 3 mils of nitric acid to 5 mils of an aqueous solution of the salt (1 in 25), cautiously evaporate the solution to dryness on a water bath, and treat the residue with a few mils of distilled water and filter the liquid. On evaporating the filtrate and washings to dryness, this residue meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"Assay.—Add about 0.3 Gm. of Exsiccated Sodium Sulphite, accurately weighed, to 50 mils of tenth-normal iodine V.S. in a glass-stoppered flask, agitate the mixture until complete solution results and titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 90 per cent. of Na_2SO_3.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.006304 Gm. of Na_2SO_3. Each gramme of Exsiccated Sodium Sulphite corresponds to not less than 142.8 mils of tenth-normal iodine V.S." *U. S.*

A. H. Clark (*Drug. Circ.*, 1914, p. 457) has reported at length upon the keeping qualities of the anhydrous salt in comparison with the hydrated crystalline form. His conclusions are in favor of the greater stability of the dehydrated salt.

Uses.—Dried sodium sulphite is used for the same purposes and in the same manner as the crystalline, except it is a little more than twice as strong and must be used in correspondingly small amounts.

Dose, eight to thirty grains (0.5–2.0 Gm.).

SODII THIOSULPHAS. U. S.

SODIUM THIOSULPHATE Sod. Thiosulph.
[Sodii Hyposulphis, U. S. 1890, Sodium Hyposulphite]

(sō′dĭ-ī thī-o-sŭl′phās)

"It contains not less than 63.07 per cent. nor more than 67.48 per cent. of anhydrous sodium thiosulphate, corresponding to not less than 99 per cent. of the crystallized salt [$Na_2S_2O_3 + 5H_2O = 248.22$]. Preserve it in well-closed containers." *U. S.*

Hyposulphite of Soda; Natrum Subsulfurosum (Hyposulfurosum); Hyposulphis Sodicus; Hyposulphite de Soude, *Fr., Cod.*; Sulfite sulfuré de Soude, *Fr.*; Natrium thiosulfuricum, *P. G.*; Natriumthiosulfat, Unterschwefligsaures Natron, *G.*; Hiposulfito sodico, *Sp.*

This salt is used in the United States and

British Pharmacopœias as a test, and for the formation of the *Volumetric Solution of Sodium Thiosulphate*. It is found only in the Appendix of the Br. It is readily prepared, according to Walchner, by mixing a pound of dry sodium carbonate, in fine powder, with five ounces of sulphur, heating the mixture gradually in a porcelain vessel until the sulphur melts, and stirring the agglutinated mass, still kept hot, in order that every portion of it may come in contact with the air. The sodium sulphide first formed is thus converted into sodium sulphite. This is dissolved in water, and the filtered solution being boiled with sulphur becomes one of sodium thiosulphate, from which, after filtration and concentration, the salt is deposited in crystals. The latter part of the reaction is as follows:

$$Na_2SO_3 + S = Na_2S_2O_3$$

It may be obtained also by digesting the solution of sodium sulphite at a high temperature, but short of ebullition, with finely divided sulphur. It is made also by oxidizing sodium hydrosulphide, according to the following reaction:

$$2NaHS + 2O_2 = 2Na_2S_2O_3 + H_2O$$

Thiosulphuric acid exists only in combination, and its salts were formerly considered simply as sulphuretted sulphites. The true hyposulphurous acid, according to theory, would be H_2SO_2, while $H_2S_2O_3$ is more properly *thiosulphuric* acid, as it differs from sulphuric acid by the replacement of one oxygen atom by one sulphur atom.

Inasmuch as Schützenberger discovered the true hyposulphurous acid, H_2SO_2, exact chemical usage would demand that we give the distinguishing name thiosulphuric to what was formerly called hyposulphurous. Schützenberger himself called the newly-discovered acid *hydrosulphurous*, but this is not characteristic, and the correct name for "sodium hyposulphite" is *sodium thiosulphate*.

Properties.—It is officially described as in "colorless, transparent, monoclinic prisms; odorless, and having a cooling, afterwards bitter taste. It is permanent in the air below 33° C. (91.4° F.), but efflorescent in dry air above that temperature; slightly deliquescent in moist air. One Gm. of Sodium Thiosulphate dissolves in 0.5 mil of water at 25° C. (77° F.); insoluble in alcohol; at boiling temperatures it is rapidly decomposed. An aqueous solution of the salt (1 in 10) is neutral or faintly alkaline to litmus. When rapidly heated the salt melts. When heated slowly until it is effloresced, and afterwards to 100° C. (212° F.), it undergoes partial decomposition, loses all of its water of crystallization, and at red heat is decomposed, sulphur being liberated, while a residue of sodium sulphide and sodium sulphate remains. To a non-luminous flame it imparts an intensely yellow color. An aqueous solution of Sodium Thiosulphate readily dissolves many compounds of silver (chloride, bromide, iodide, oxide, etc.) and discharges the color of a solution of iodine or of starch iodide. Add a few drops of ferric chloride T.S. to 5 mils of an aqueous solution of the salt (1 in 10); a dark violet color is produced which disappears rapidly upon agitation. The addition of sulphuric or hydrochloric acid to an aqueous solution of Sodium Thiosulphate liberates sulphur dioxide (recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the escaping gas); a white precipitate of sulphur is also formed (distinction from *sulphite or bisulphite*). An aqueous solution of the salt (1 in 20) is not rendered turbid by the addition of ammonium oxalate T.S. (*calcium*). Add 10 mils of diluted hydrochloric acid to 1 Gm. of the salt, evaporate it to dryness on a water bath, heat the residue with 50 mils of distilled water and filter. Ten mils of this filtrate does not respond to the Test for heavy metals (see Part III, Test No. 3). Add 3 mils of nitric acid to 5 mils of an aqueous solution of the salt (1 in 25), evaporate the solution cautiously to dryness on a water bath, treat the residue with a few mils of distilled water, filter the liquid and evaporate the filtrate and washings to dryness; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Dissolve about 1 Gm. of Sodium Thiosulphate, accurately weighed, in about 20 mils of distilled water and titrate with tenth-normal iodine V.S., starch T.S. being used as indicator. It shows not less than 63.07 per cent. nor more than 67.48 per cent. of $Na_2S_2O_3$.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.015814 Gm. of $Na_2S_2O_3$. Each gramme of Sodium Thiosulphate corresponds to not less than 39.9 mils nor more than 42.7 mils of tenth-normal iodine V.S." *U. S.*

Its solution dissolves silver chloride and all water-insoluble compounds of that metal, except the sulphide, and that resulting from the decomposition of a silver salt by light. Though without action on potassium iodide, it dissolves iodine, decomposes iodic acid with liberation of iodine, and destroys the blue color of starch iodide. (Brande and Taylor.) In dissolving iodine it forms with it sodium iodide and sodium tetrathionate, as represented by the formula

$$2(Na_2S_2O_3) + I_2 = (NaI)_2 + Na_2S_4O_6$$

It dissolves also lead sulphate and iodide, and calcium sulphate, much more freely than does water. (*J. P. C.*, 1864, 363.) Its relations to iodine render it valuable as a means of estimating the quantity of free iodine, for which purpose it is used in the Pharmacopœias in the form of a *volumetric solution*. In consequence of its peculiar solvent properties, it is much used in photography. The photographers employ it for the purpose of dissolving the unchanged silver iodide or bromide from the plate after the action of the light, and thus fixing the image already formed. It is also largely used as an "*antichlor*" in the paper manufacture, to free the paper pulp from the excess of chlorine used

in the bleaching. One of the most delicate tests is that of iodine with starch. The blue color produced by the mixture of very small quantities of these two substances in solution is instantly discharged by a solution containing a trace of the thiosulphate. If zinc or iron is dipped into an acidified solution of the thiosulphate, the liberated hydrogen at once reduces the sulphurous oxide which is in the solution to hydrogen sulphide, recognizable by lead acetate paper. This test will serve to show even traces of thiosulphate.

Uses.—Probably because of its confusion with the hyposulphite, sodium thiosulphate is recommended by many authorities in the treatment of various parasitic *diseases of the skin* and in yeasty fermentation in the stomach. It is not probable that the thiosulphate possesses any medicinal virtues, although sodium hyposulphite is certainly an active remedy. Trousseau (*R. T.*, 1905, p. 136) has recommended sodium thiosulphate in five per cent. solution as a topical application in *blepharitis* and *conjunctivitis*.

Dose, ten to twenty grains (0.65–1.3 Gm.), three times a day simply dissolved in water, or in the form of syrup. For external use a drachm may be dissolved in a fluidounce of water.

SODIUM

SODIUM

(sō'dĭ-ŭm)

"The metal sodium as met with in commerce. It should be preserved in well-stoppered bottles under mineral naphtha." *Br.*, 1898.

Sodium, *Fr.*; Natrium, Natronmetall, *G.*; Sodio, *It.*, *Sp.*

Sodium is a peculiar metal, the hydroxide of which is known as the alkali "soda." It was discovered by H. Davy in 1807, who obtained it in small quantity by decomposing the alkali by the agency of galvanic electricity. Sodium was formerly prepared on a large scale by igniting an intimate mixture of dry sodium carbonate, coal, and chalk. The amount of metal obtained by this method is, however, not over 40 per cent. of the theoretical result. A much improved process was next brought out by Castner (*J. Soc. Chem. Ind.*, 1887, 174), in which an iron carbide, or a mixture of fine iron and coke, is used to reduce the caustic soda, according to the reaction:

$$6NaOH + FeC_2 = 2Na_2CO_3 + 6H + Fe + 2Na$$

The reduction of the sodium hydroxide takes place at a temperature of about 800° C. (1472° F.), and is carried out in steel crucibles, each of which holds 5.6 kilos of sodium hydroxide and 1.97 kilos of carbide. The product of the reaction consists of about 4.85 kilos of sodium carbonate and 0.933 kilo of metallic sodium. This latter collects in a receiver connected with the top of the crucible, while the sodium carbonate is dissolved out from the residue and is causticized preparatory to being used again. This process in turn has been replaced by the electrolytic processes. The most successful of these is that of Castner, who uses an electrolyte of fused sodium hydroxide in an iron pot or crucible with an anode of iron and a cathode of copper. The sodium is reduced at a comparatively low temperature, and is ladled from the vessel into moulds. The process is carried out at present on a large scale by the Niagara Electro-Chemical Co., and at Oldbury, England, and several places in Germany.

Sodium is a soft, malleable, ductile solid, of a silver-white color. It possesses the metallic luster in a high degree, when protected from the action of the air, by which it is quickly tarnished and oxidized. Its sp. gr. is 0.97, and its fusing point 95.6° C. (204° F.). Its chemical affinities resemble those of potassium, but are less energetic. Like potassium, it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on warm water it inflames. In both cases the water is decomposed, hydrogen is liberated, and sodium hydroxide generated. Like potassium, if exposed with a bright surface to the air, it undergoes a slow combustion, which renders it luminous in the dark. It combines with oxygen to form the monoxide, Na_2O, and a peroxide, Na_2O_2. This latter oxide is always formed when the metal is burned in the open air. It is officially described as "A soft metal, rapidly oxidizing in the air, but showing a bright metallic surface when freshly cut. It violently attacks water or alcohol (90 per cent.), with evolution of hydrogen, little or no insoluble matter remaining. It imparts an intense yellow color to flame. Each gramme very cautiously added to water affords a solution which should require for neutralization at least 42.6 cubic centimetres of the volumetric solution of sulphuric acid." *Br.*

Sodium is a constituent of many important medicinal preparations. Sodium salts are characterized by communicating to the blowpipe flame a rich yellow color, and by not being precipitable by any reagent except potassium metantimoniate. Sodium monoxide consists of two atoms of sodium and one atom of oxygen. This reacts with water to form sodium hydroxide (caustic soda),

$$Na_2O + H_2O = 2NaOH$$

The dioxide (or peroxide), Na_2O_2, is now manufactured on a large scale from the metal, and used as a substitute for hydrogen peroxide in bleaching processes. It forms a canary-yellow powder, which decomposes rapidly in the presence of moisture.

Uses.—Sodium occurs in the human body in larger amount than any other metal. It is the most nearly inert physiologically of all the earths. It is, therefore, the base of choice when

it is desired to obtain the effect of an acid radical, as an iodide, bromide or nitrite. For the effects of massive doses of sodium, see *Sodii Carbonas.*

SPARTEINÆ SULPHAS. U. S

SPARTEINE SULPHATE Spartein. Sulph.

(spär-tē-ĭ'næ sŭl'phăs)

"The sulphate [$C_{15}H_{26}N_2.H_2SO_4 + 5H_2O$ = 422.39] of sparteine, a liquid alkaloid obtained from *Cytisus Scoparius* (Linné), Link (Fam. *Leguminosæ*). Preserve it in well-closed containers, protected from light." *U. S.*

Sulfate de Spartéine, *Fr. Cod.*; Sparteinum Sulphuricum; Sparteinsulfat, Schwefelsaures Spartein, *G.*; Sulfato de esparteina, *Sp.*

This alkaloidal salt, prepared from Scoparius (see page 985) is officially described as in "colorless, rhombohedral crystals, or as a crystalline powder; odorless, and having a slightly saline and somewhat bitter taste. It is hygroscopic. One Gm. of Sparteine Sulphate dissolves in 1.1 mils of water and in 3 mils of alcohol at 25° C. (77° F.); insoluble in chloroform or ether. Its aqueous solution (1 in 20) is neutral or acid to litmus. Add 25 mils of ether and a few drops of diluted ammonia water, avoiding an excess, to about 0.1 Gm. of Sparteine Sulphate in a test tube, then add to the mixture an ethereal solution of iodine (1 in 50) until the liquid, when shaken, turns from an orange to a dark reddish-brown color. After a short time, the bottom and sides of the test tube will be coated with minute, dark greenish-brown crystals. Barium chloride T.S. produces a white precipitate insoluble in hydrochloric acid when added to an aqueous solution of Sparteine Sulphate. Incinerate about 1 Gm. of Sparteine Sulphate; not more than 0.1 per cent. of ash remains. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is colorless (*readily carbonizable organic impurities*). Shake about 0.1 Gm. of Sparteine Sulphate in a test tube with 5 mils of potassium hydroxide T.S., the liquid at first becomes turbid, and small, colorless or nearly colorless drops of sparteine gradually collect on the surface. Suspend a strip of moistened red litmus paper in the mouth of a test tube, and apply a gentle heat; the test paper gradually acquires a blue color, but no odor of ammonia is perceptible (*ammonium salts*). A mixture of about 0.1 Gm. of Sparteine Sulphate, 0.5 mil of chloroform and 0.5 mil of alcoholic half-normal potassium hydroxide V.S. does not emit an odor of phenylisocyanide on heating (*aniline*)." *U. S.*

G. Marque (*J. P. C.*, xxx, 555) states that if a small quantity of sparteine sulphate be mixed with about one-third of its weight of chromium trioxide, and gently heated in a porcelain dish, the mass will soon turn green and emit a strong odor resembling coniine. Moureu and Villier (*Bull. Soc. Chim.*, 1903 (6), 12, 545) confirm Stenhouse's formula for sparteine sulphate, $C_{15}H_{26}N_2.H_2SO_4 + 5H_2O$. (For description of *Oxysparteine,* see Part II.)

Uses.—The statements of different investigators both clinical and pharmacological, concerning the effects of sparteine have been so extraordinarily contradictory that they are at present impossible of reconciliation; one is perforce driven to the belief that the different investigators did not have the same principle. It has been variously claimed to accelerate and to slow the pulse rate, to increase and to diminish the contractile power of the heart, to arrest the heart in systole and in diastole, to raise the blood pressure or to lower it, and finally to have no effect on the circulation whatsoever. Again it is claimed by some that it diminishes, and by some that it increases the quantity of urine, and by others that it has no effect upon the kidney. These discrepancies cannot be harmonized on the ground of difference in dosage. For review of the extensive literature upon the subject, the reader is referred to McNider (*Southern Med. Journ.*, 1910, iii, p. 498), and to Pilcher and Sollmann (*J. P. Ex. T.*, 1915, vi, p. 373). It has been used clinically in the treatment of various forms of cardiac disorders, such as *endocarditis,* but especially in such functional derangements as *nervous palpitation,* the *tachycardia of Grave's disease,* etc. It has also been employed as a diuretic in *dropsies,* especially when due to cardiac lesions. The doses recommended by various authors have ranged from one-sixth of a grain to as high as two grains (0.010–0.13 Gm.).

SPIGELIA. U. S.

SPIGELIA [Pinkroot]

(spĭ-gē'lĭ-ą)

"The dried rhizome and roots of *Spigelia marilandica* Linné (Fam. *Loganiaceæ*), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." *U. S.*

Maryland, Carolina or Indian Pink, Worm-grass, Wormweed, American worm-root, Star-bloom; Spigelie du Maryland, *Fr.*; Marylandische Spigelie, Spigelie, *G.*; Spigelia, *It.*

Two species of *spigelia* have attracted attention as anthelmintics—*S. Anthelmia* L., of South America and the West Indies, and *S. marilandica* L. of this country. *Spigelia Anthelmia* L., of South America is an annual plant, from one or two feet in height, with thin, shortly petioled leaves, those of the lower stem being lanceolate, those above varying from very broadly lanceolate to ovate, with a distinct tendency to a rhomboidal outline and attaining a length of over four inches. It is much used as an anthelmintic in its native country, and its rhizome is said to have appeared in the European markets. The only specimens which we have seen, however, have been the whole dried plant, of which the attached rhizomes are much smaller and the rootlets much finer than in the North American species. It is affirmed that in overdoses this rhizome is a powerful poison, which has caused death not only in the domestic animal but also in man.

The *Carolina pink* (*Spigelia marilandica*) is

an herbaceous perennial plant. The stems, several of which rise from the same rhizome, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate-lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a one-sided spike, and supports from four to twelve flowers with very short peduncles. The calyx is persistent, with five long, subulate, slightly serrate leaves, reflexed in the ripe fruit. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine color externally, paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens, though apparently very short, and inserted into the upper part of the tube between the segments, may be traced down its internal surface to the base. The anthers are oblong, heart-shaped; the ovary superior, ovate; the style about the length of the corolla, and terminating in a linear fringed stigma projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions, with many seeds.

The plant is a native of our Southern and Southwestern States, being seldom found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The rhizome and roots are the only portions recognized in the Pharmacopœias. The drug was formerly collected in Georgia and the neighboring States by the Creek and Cherokee Indians, who disposed of it to the white traders. After the emigration of the Indians, the supply of spigelia from this source very much diminished, and at one time it nearly if not quite ceased. But a new source of supply was opened from the Western and Southwestern States, and it is now again obtainable. The commercial supplies being so restricted, some attention has been given to the cultivation of the plant. The Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., has grown spigelia under shade, and Miss Henkel states that it is readily cultivated in Georgia. (*D. C.*, lvi, p. 132.)

No drug has had a commercial history like spigelia. For twenty years or more it was largely substituted by *Ruellia ciliosa* Pursh. Sanders reported examining 57 samples of pinkroot which were obtained from various sections of the country and none were genuine. (*Jour. A. Ph. A.*, 1912, p. 502.) To Prof. Greenish (*A. J. P.*, 1891, p. 226) belongs the credit for the first pharmacognostic description of this common substitute, although he incorrectly attributed it to *Phlox carolina* L. (*P. ovata* L.). He pointed out that it was distinguished by the fact that it contained stone cells and cystoliths of calcium carbonate. Greenish's work was confirmed by Holm (*A. J. P.*, 1906, p. 553) and by Stockberger (*Ph. Rev.*, 1907, p. 2). His false identification continued in literature for several years, probably owing to the statements of the large drug houses which make a specialty of collecting American drugs. (*Proc. A. Ph. A.*, 1909, p. 1171.) The presence of *Phlox ovata* L. in commercial lots of spigelia has not been confirmed, and Kraemer illustrates the pharmacognosy of the rhizome and roots of this drug in *A. J. P.*, 1910, p. 470. Moser, however, affirms that *Phlox ovata* and *P. glaberrima* L. are frequently collected and sold as spigelia. (*A. J. P.*, 1909, p. 576.) Among some of the adulterants which have been identified are the rhizomes of goldenseal and caulophyllum, although a large variety of rhizomes are no doubt more or less intermixed.

Properties.—Pinkroot is officially described as "rhizome horizontal or slightly oblique, more or less flexuous, somewhat branched, from 1.5 to 5 cm. in length and from 2 to 5 mm. in diameter; externally dark brown, slightly annulate, with scars of bud scales, the upper surface knotty from approximate stem-bases, bearing cup-shaped scars; from the lower and lateral portions arise numerous, long, rather coarse, sparingly branched, brittle roots; fracture short, internally differentiated into three nearly equal zones of pith, wood and bark; odor slightly aromatic; taste bitter, pungent. Few if any of the roots exhibit thin, terminal portions with the bark stripped from the slender strands of wood. Stems usually attached to the upper portion of the rhizome, nearly cylindrical, attaining a length of 6 cm. and a diameter of 3 mm., light grayish-brown to purplish-brown, nodes annulate, marked by opposite leaf-scars. Under the microscope, transverse sections of the rhizome of Spigelia show a dark brown, more or less exfoliated epidermal layer; a cortex composed of from 10 to 15 rows of starch-bearing parenchyma; a distinct zone of sieve tissue from 0.075 to 0.15 mm. in width; a compact woody area composed of tracheæ and tracheids which are hardly distinguishable from each other, both kinds of vessels being marked with bordered pores; an internal sieve closely resembling the sieve in the bark; and a pith composed of fairly uniform, nearly polygonal, thin-walled cells, more or less filled with small starch grains. Transverse sections of the root show a large cortex, the cells of which are more or less filled with small starch grains and a central stele of 6 or 8 radial fibro-vascular bundles, which in the older roots are united by a strong development of lignified cells. The stem in transverse section is distinguished from the rhizome by a narrower woody zone, the tracheæ having spiral thickenings, and by a nearly uninterrupted circle of non-lignified bast-fibers in the bark. The powder is grayish-brown; when examined under the microscope it exhibits starch grains generally numerous, at times, however, few, spherical or slightly angular, from 0.002 to 0.006 mm. in diameter; fragments of lignified tracheæ and tracheids conspicuous; fragments of tracheæ with spiral thickening relatively few; bast-fibers few, very long, non-lignified; occasional fragments of the red-

dish-brown epidermal cells. Spigelia yields not more than 10 per cent. of ash." *U. S.*

The virtues of spigelia are extracted by boiling water. The root, analyzed by Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassium and calcium, etc., and woody fiber. The principle upon which the virtues of the root are thought to depend is brown, of a bitter nauseous taste, like that of the purgative matter of the leguminous plants, and when taken internally produces vertigo and a kind of intoxication. An analysis of the root by R. H. Stabler yielded as results a bitter uncrystallizable principle upon which the virtues of the medicine are supposed to depend, a little volatile oil, tannic acid, inert extractive, wax, resin, lignin, and salts of sodium, potassium, and calcium.

The active principle is a volatile alkaloid discovered by W. L. Dudley (*Am. Chem.*, vol. i, p. 150), who, on the contrary, found that the active principle of spigelia is a volatile alkaloid. He made it by distilling the ground root with milk of lime over a paraffin bath, and collecting the distillate in hydrochloric acid. After evaporation to dryness, the residue is taken up with alcohol and crystallized out of solution. He compared the reactions of this alkaloid, which he called *spigeline*, with those of nicotine, coniine, and lobeline. Spigeline yields a brownish-red precipitate with a solution of iodine in potassium iodide, a white crystalline precipitate with potassio-mercuric iodide, and a white flocculent precipitate with meta-tungstic acid. Boorsma (*P. J.*, 1898, 89) found 0.0005 Gm. of *spigeline* to be lethal to guinea pigs.

Uses.—The activity of spigelia is somewhat diminished by time. Spigelia is generally considered among the most powerful anthelmintics, especially esteemed against the *round-worm*. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it is said to cause vertigo, dimness of vision, dilated pupils, spasms of the facial muscles and of the eye-lids, and even general convulsions. The death of two children who expired in convulsions was attributed to it by Chalmers. H. A. Hare (*Med. News*, March, 1887) has found that in the lower animals it produces symptoms similar to those just described, namely, dilatation of the pupil, exophthalmia, strabismus, progressive muscular weakness of spinal origin, cardiac depression, and death from failure of respiration. The narcotic effects are said to be less likely to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great, as it is in very general use in the United States, in both regular and domestic practice, and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia, first learned from the Cherokee Indians, were made known to the medical profession by Lining, Garden, and Chalmers, of South Carolina.

It may be given in substance or infusion, or as the fluidextract. The infusion may be made by macerating half a troyounce of the root in a pint of boiling water. It is usually combined with senna or some other cathartic, to insure its action on the bowels. A preparation much sold under the name of *worm tea* consists of spigelia, senna, manna, and savin, mixed together, in various proportions, to suit the views of different individuals.

Dose, of the powdered root, for an adult, one or two drachms (3.9–7.7 Gm.), to be repeated morning and evening for several days successively, and then followed by a brisk cathartic.

Off. Prep.—Fluidextractum Spigeliæ, *U. S.*

SPIRITUS

SPIRITS

(spĭr'ĭ-tŭs)

Alcoolats, *Fr.*; Geiste, *G.*; Spirito, *It.*

Spirits, as the term is here used, are alcoholic solutions of volatile principles formerly in general procured by distillation, but now frequently prepared by simply dissolving the volatile principle in alcohol or diluted alcohol. The distilled spirits are prepared chiefly from aromatic vegetable substances, the essential oils of which rise with the vapor of alcohol and condense with it in the receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case it is necessary to employ diluted alcohol or proof spirit, with the water of which the oil comes over in the latter part of the process. As the proof spirit of commerce is often impregnated with foreign matters, which give it an unpleasant flavor, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the U. S. Pharmacopœia. In preparing the spirits, care should be taken to avoid the color and empyreumatic flavor arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled, and, as a rule, the heat should be applied by means of a water bath, or of steam. The aromatic should be macerated for some days with the alcohol before being submitted to distillation, as the oil, being thus dissolved, rises more readily with the spirituous vapor than when confined in the tissue.

The aromatic spirits are used chiefly to impart a pleasant odor and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in *flatulent colic*, and as agreeable stimulants in *debility of the stomach*.

SPIRITUS ÆTHERIS. U. S., Br.

SPIRIT OF ETHER Sp. Æth. [Hoffmann's Drops]

(spĭr'ĭ-tŭs æ'thẹ-rĭs)

Liquor Anodynus Mineralis Hoffmanni; Ether officinal alcoolisé, *Fr. Cod.;* Ether sulfurique alcoolisé, Liqueur d'Hoffmann, *Fr.;* Spiritus Ætherеus, *P. G.;* Aetherweingeist, Hoffmannsche Tropfen, *G.;* Etere con alcool, Liquore anodino di Hoffmann, *It.;* Eter sulfuricq alcoholizado, Licor anodino mineral de Hoffmann, *Sp.*

* "Ether, *three hundred and twenty-five mils* [or 10 fluidounces, 475 minims]; Alcohol, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the ether with a sufficient quantity of alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.* "Ether, 500 *millilitres;* Alcohol (90 per cent.), 1000 *millilitres.* Mix. Specific gravity 0.802 to 0.806." *Br.*

This preparation is merely ether diluted with about twice its volume of alcohol. Although introduced into the U. S. P., 1880, it does not seem to have been employed to any extent, and it might have been dropped with advantage at a later revision. The corresponding preparation of the German Pharmacopœia contains less ether, being made of one part of ether to three parts of alcohol, both by weight. Prepared with materials of proper strength, its sp. gr. is 0.802 to 0.806. *Br.*

The spirit of ether is used chiefly as a carminative in *flatulent colic.* Although not so frequently employed as the former U. S. P. *compound spirits of ether,* which is now official in the N. F. (see *Spiritus Ætheris Compositus,* Part III), it has all the therapeutic virtues of that preparation. It may also be employed as a diffusible heart stimulant. The Compound Spirit of Ether is commonly known as *Hoffmann's Anodyne.*

Dose, one to three fluidrachms (3.75–11.25 mils).

SPIRITUS ÆTHERIS NITROSI. U. S., Br.

SPIRIT OF NITROUS ETHER Sp. Æth. Nitros. [Sweet Spirit of Nitre]

(spĭr'ĭ-tŭs æ'thẹ-rĭs nī-trō'sī)

"An alcoholic solution of ethyl nitrite [$C_2H_5NO_2 = 75.05$], containing not less than 3.5 per cent. nor more than 4.5 per cent. of $C_2H_5NO_2$. Preserve it in small, well-stoppered, dark amber-colored bottles, in a cool and dark place, remote from fire." *U. S.* "Spirit of Nitrous Ether is an alcoholic solution containing not less than 1.52 or more than 2.66 per cent. by weight of ethyl nitrite, together with aldehyde and other allied substances. It should be kept in well-closed vessels; preferably in a cool dark place, and in small amber bottles." *Br.*

Spiritus Nitri Dulcis; Spiritus Ætheris Nitrici; Spiritus Nitrico-æthereus; Ether Azoteux Alcoolisé, Liqueur anodine nitreuse, *Fr.;* Spiritus Ætheris nitrosi, *P. G.;* Versüsster Salpetergeist, *G.;* Etere nitroso officinale, Spirito d'etere nitroso, *It.;* Espiritu de nitro dulce, *Sp.*

* "Sodium Nitrite, *one hundred grammes* [or 3 ounces av., 231 grains]; Sulphuric Acid, *forty mils* [or 1 fluidounce, 169 minims]; Monohydrated Sodium Carbonate, *six-tenths of a gramme* [or 9 grains]; Potassium Carbonate, completely deprived of water by heating, *three grammes* [or 46 grains]; Alcohol, Water, each, *a sufficient quantity.* Mix the sulphuric acid with *one hundred and twenty mils* [or 4 fluidounces, 28 minims] of water, cool the liquid, add *eighty-five mils* [or 2 fluidounces, 420 minims] of alcohol previously diluted with an equal volume of water, and introduce the solution into a 1000 mil [or 2 pint] flask, surrounded by a mixture of ice and water. Dissolve the sodium nitrite in *two hundred and eighty mils* [or 9 fluidounces, 225 minims] of water, filter, and, having poured the filtrate into a separatory funnel, allow the liquid to slowly drop into the flask containing the acid mixture. When all has been added and the reaction is complete, allow any crystals which may have formed to settle at the bottom of the flask, and decant the cold mixture of ethyl nitrite and aqueous solution quickly to the previously cooled separatory funnel, and draw off and discard the aqueous liquid. Wash the separated ethyl nitrite, first, with *twenty mils* [or 325 minims] of ice-cold water, and then remove any traces of acid by washing it with *fifteen mils* [or 243 minims] of ice-cold water, in which the monohydrated sodium carbonate has previously been dissolved. Carefully separate the ethyl nitrite from the aqueous liquid, and agitate it in a well-stoppered bottle with the potassium carbonate to remove traces of water. Then cool the liquid, decant, and pour the ethyl nitrite immediately into a tared bottle containing *five hundred grammes* [or 17 ounces av., 279 grains] of alcohol. Ascertain the weight of the ethyl nitrite poured into the alcohol by noting the increase in weight of the tared bottle and contents, and then add enough alcohol to make the mixture weigh *twenty-two times* the weight of the ethyl nitrite added. Lastly, transfer the product to small, well-stoppered, dark, amber-colored bottles, and keep these in a cool place, remote from fire." *U. S.*

"Nitric Acid, 150 *millilitres;* Sulphuric Acid, 100 *millilitres;* Copper of commerce, in wire or turnings, 100 *grammes;* Alcohol (90 per cent.), *a sufficient quantity.* To one thousand millilitres of the Alcohol add gradually the Sulphuric Acid, and then one hundred and twenty-five millilitres of the Nitric Acid, stirring constantly. Transfer the mixture to a retort or flask, in which the fragments of copper have been placed, and to which is attached an efficient condenser with a receiver containing one thousand millilitres of the Alcohol. Surround the receiver with ice-cold water and distil gently at a temperature which is at first about 77° C. (170.6° F.), and rises to 80° C. (176° F.), but does not exceed 82° C. (179.6° F.), until the volume of liquid in the receiver has been increased to sixteen hundred millilitres. Then allow the contents of the retort to cool, introduce the remaining twenty-five millilitres of Nitric Acid, and resume the distillation as before, until the liquid in the receiver has been increased to seventeen hundred

millilitres. Mix this liquid with one thousand millilitres of the Alcohol, or with as much as will make the product contain 2.66 per cent. by weight of ethyl nitrite when tested as described in the following paragraph." *Br.*

The official spirit of nitrous ether is a mixture of nitrous ether or ethyl nitrite, $C_2H_5NO_2$, and alcohol (rectified spirit). For many years, spirit of nitrous ether was made by acting on alcohol with nitric acid, and the present British process and that of the U. S. P., 1880, are constructed on this plan. The U. S. P. VIII and IX processes differed essentially; in these, the use of nitric acid was abandoned, sodium nitrite being substituted as the source of the nitrous compound. Ethyl nitrite is readily generated by the reaction of nitric acid with alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid.

In the U. S., 1860, process, which was modelled after the plan of Squibb, the nitric acid and alcohol were directly mixed in a retort. The liquid condensed in the receiver was mixed with potassium carbonate, and again distilled, in order to free it from the acid which had come over with the nitrous ether, and, being too strong was diluted with alcohol, and thus brought to the state of *spirit* of nitrous ether. It was a great improvement over the formula of earlier Pharmacopœias, and had the merit of insuring a preparation of more uniform strength. But in the Pharmacopœia of 1870 the British process was substituted, as even better than it.

The U. S., 1880, process differed in several particulars from those formerly official. Copper was no longer used. The use of this metal originated with Redwood, under the impression that the nitrous radical was liberated by it and enabled to unite more readily with the ethyl of the alcohol, to form ethyl nitrite. Upon the small scale the copper served a useful purpose in controlling and moderating the reaction, but excellent results have been obtained by substituting broken glass, and quite as large a yield of ethyl nitrite is obtained. The nitric acid was not added in two portions, but the whole quantity was mixed with the sulphuric acid and alcohol at first. This was an improvement. The direction to "heat rapidly, by means of a water-bath, until strong reaction occurs and the temperature reaches 80° C. (176° F.)," was likely to cause loss in the hands of the inexperienced through excessive action, and inability to condense all the vapor of ethyl nitrite which would be suddenly generated. A temperature of 72° C. (161.6° F.) was amply sufficient to start the reaction, and as soon as effervescence took place the heat should have been *at once removed,* and not reapplied until the reaction slackened, so that a uniform and not an excessive reaction might be maintained. The greatest change was, however, in purifying the distillate by agitating it with ice cold distilled water, separating the ethereal layer and mixing it with alcohol, so that the finished product should contain 5 per cent. by weight of the crude ethyl nitrite. A thoroughly effective method of separating ethyl nitrite from its solution in alcohol and water is yet to be discovered. Some manufacturers agitate the distillate with a saturated solution of calcium chloride to separate the ethyl nitrite, and the British Pharmacopœia once used this method as a test.

The U. S. P., 1890, process overcame these objections by generating the nitrous compound necessary to effect the combination with ethyl by acting on sodium nitrite with sulphuric acid in the presence of alcohol, the violence of the reaction being controlled by diluting both the sulphuric acid and the alcohol with water, and by using an aqueous solution of the nitrite. A very thorough means of refrigeration had to be used, on account of the extreme volatility of the distillate, and because evolution of ethyl nitrite commenced before all the sulphuric acid was added and without the use of any other heat than that generated by the chemical reaction. Heat was not applied until the reaction became slower, and then only very moderately and capable of being instantly withdrawn if necessary. The advantages of this process are that the production of aldehyde and acetic ether is avoided, through the absence of nitric acid, and pure ethyl nitrite is easily obtained. Sodium nitrite can be procured of standard purity, although the impurities in the commercial salt do not affect the character of the ethyl nitrite. The use of alkaline nitrites in making ethyl nitrite is not new, as both potassium and sodium nitrites have been employed, Feldhaus, Dunstan, Dymond, and others having published processes; Frerichs, of St. Louis, used the method on a large scale, and C. O. Curtman and E. L. Patch, of Boston, also recommended its employment. (See *Am. Drug.,* 1893, p. 171.) An improvement was made in the U. S. P. VIII process and in the cold processes previously proposed by reversing the order of mixing the liquids in the flask; in the former pharmacopœial process the acid solution was dropped slowly into the sodium nitrite solution and alcohol; this caused some loss of ethyl nitrite with evolution of nitrogen tetroxide, on the other hand, in the present official cold process if carefully conducted with sufficient refrigeration, the production of ethyl nitrite takes place uniformly and slowly with very little loss. The great advantage, however, in this process consists in the avoidance of distillation and use of heat in preparing this very volatile product.

The present British formula rejects the sodium nitrite process, but introduces under *Liquor Ethyl Nitritis* (see page 632) a solution made by decomposing sodium nitrite in the presence of alcohol, and diluting the ethyl nitrite produced, with alcohol containing a little glycerin. It is unfortunate that both preparations were not made of the same strength, the solution containing 3 per cent., the spirit only 2 per cent., of ethyl nitrite; the solution contains no aldehyde, but the spirit is permitted to contain aldehyde and other substances.

Assay.—The U. S. P. and the Br. Ph. quantitative test is based on Allen's method, differing only in the relative quantities of the reagents. (See p. 1051; also paper by Curtman, *Proc. Missouri Pharm. Assoc.*, July, 1892; *A. J. P.*, 1898, 273.)

"Transfer about 40 mils of Spirit of Nitrous Ether, which has been previously shaken with 0.5 Gm. of powdered potassium bicarbonate, to a tared, 100 mil measuring flask, and weigh it accurately. Add sufficient alcohol to bring the volume to exactly 100 mils and mix thoroughly. Introduce into a nitrometer (see Part III, Gasometric Estimation) exactly 10 mils of the alcoholic solution, follow it by 10 mils of potassium iodide T.S., and afterwards by 5 mils of diluted sulphuric acid. When the volume of gas has become constant (within thirty to sixty minutes), note the volume of gas collected. Multiply this volume in mils by 0.307, and divide the product by one-tenth of the weight in grammes of the Spirit of Nitrous Ether taken. At standard temperature and pressure, the quotient represents the percentage of ethyl nitrite in the liquid. The temperature correction is one-third of 1 per cent. of the total percentage just found for each degree, additive if temperature is below, subtractive if above, 25° C. (77° F.). The barometric correction is four-thirtieths of 1 per cent. of the total percentage just found for each mm., additive if above, subtractive if below, 760 mm." *U. S.*

Allen's Test for Ethyl Nitrite.—A nitrometer should be filled with strong brine, and 5 mils of the sample to be tested should be placed in the cup of the nitrometer, and allowed to enter through the tap, taking care that no air gets in at the same time. Five mils of a strong solution of potassium iodide is next allowed to enter, and this is followed by about 5 mils of dilute sulphuric acid. Effervescence immediately ensues, and, if the tube be vigorously agitated at intervals, the reaction will be complete in five minutes, when the level of the liquid in the two limbs of the nitrometer is adjusted, and the volume of nitrogen dioxide gas read off. If the volume of gas evolved be small, another 5 mils of the sample should be let into the nitrometer, and the agitation repeated. The reaction is:

$$(C_2H_5)NO_2 + KI + H_2SO_4 = (C_2H_5)OH + KHSO_4 + I + NO$$

When strictly accurate results are not required, the volume of gas need not be corrected for variations of pressure, temperature, and tension of aqueous vapor, and if these considerations be omitted the calculation will be much simplified. Thus, if 0.030 gramme of nitrogen dioxide (representing 0.075 gramme of $C_2H_5NO_2$) under the *ordinary* conditions of pressure and temperature be taken to measure 23.55 mils, then

$$\frac{\text{volume of gas in mil} \times 0.3185}{\text{measure of sample in mil} \times \text{density of sample}} = \text{percentage by weight of } C_2H_5NO_2$$

If the density of the sample be omitted from the equation, the result will be the number of grammes of ethyl nitrite per 100 mils of the sample.

The nitrometer method has been proved to give very good results with pure sodium nitrite (prepared from silver nitrite) employed in known amount. The results with spirit of nitrous ether are somewhat higher than those given by Eykman's method, the difference being least when sodium chloride is employed in the latter process and time is given for the ferrous solution to react thoroughly on the solution of ethyl nitrite. The results by the iodide method are almost certainly more accurate than those by Eykman's process. With most specimens of sweet spirit of nitre a considerable amount of nitric oxide is produced (and iodine liberated) before adding the acid, the reaction probably depending on the presence of free acid in the sample. The results obtained in the nitrometer are remarkably constant, and the method furnishes a very easy means of assaying sweet spirit of nitre with considerable accuracy, which is further increased if a correction of 1.5 mils (= 0.0048 gramme of $C_2H_5NO_2$) be made for solubility of the gas. The process has the advantage of great ease and rapidity, and actually measures the nitrous compounds present in the sample, instead of leaving their proportions to be inferred from a more or less complex reaction, such as the reduction of permanganate, and others.

Theory of the Production of Nitrous Ether, etc.—The reaction in the U. S. P. IX process may be expressed as follows:

$$2C_2H_5OH + 2NaNO_2 + H_2SO_4 = 2C_2H_5NO_2 + Na_2SO_4 + 2H_2O$$

Alcohol, sodium nitrite, and sulphuric acid when brought in contact yield ethyl nitrite, sodium sulphate, and water.

The nitric acid process may be explained as follows: One molecule of nitric acid, by reacting with one molecule of alcohol, forms one molecule of nitrous acid, one molecule of aldehyde, and one molecule of water, thus:

$$HNO_3 + C_2H_6O = HNO_2 + C_2H_4O + H_2O$$

The nitrous acid, as soon as formed, reacts with a second molecule of alcohol, so as to form one molecule of nitrous ether or ethyl nitrite, with separation of one molecule of water, according to the reaction:

$$C_2H_5.OH + HNO_2 = C_2H_5NO_2 + H_2O$$

In the process of the British Pharmacopœia the nitric acid is converted into nitrous acid by the reducing action of metallic copper and sulphuric acid, the reaction being:

$$HNO_3 + Cu + H_2SO_4 = HNO_2 + CuSO_4 + H_2O$$

The nitrous acid now reacts with the alcohol as in the previous reaction, so as to produce the nitrous ether. The object of using the sulphuric acid is to economize the nitric acid.

Properties of Ethyl Nitrite.—*Pure* ethyl nitrite is pale yellow, has the combined odor of apples and Hungary wine, boils at 18° C. (64.4°

F.), and has the sp. gr. 0.900 at 15.5° C. (60° F.). The density of its vapor is 2.627. Litmus is not affected by it. When it is mixed with an alcoholic solution of potassium hydroxide, potassium nitrite and alcohol are formed, without producing a brown color, showing the absence of aldehyde. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue. The impure ether, as formerly obtained by the Edinburgh and Dublin processes for subsequent dilution to form sweet spirit of nitre, boiled at 21.1° C. (70° F.), and had the density of 0.886 at 4.4° C. (40° F.). The specific gravity assigned to it by the Edinburgh College was 0.899. Mixed with an alcoholic solution of potassium hydroxide, it became dark brown, with production of *aldehyde resin.* This discoloration showed the presence of aldehyde. When kept, it became acid in a short time, as shown by litmus, and nitric oxide was given off, which often caused the bursting of the bottle. Its tendency to become acid was rendered greater by the action of the air, and depended on the absorption of oxygen by the aldehyde, which thereby became oxidized to acetic acid.

Ethyl nitrite in hermetically sealed glass tubes is found in commerce, affording a ready means of preparing small quantities of spirit of nitrous ether, which deteriorates on keeping; as pure ethyl nitrite boils at 18° C. (64.4° F.) the tubes should be cooled and opened and the liquid immediately diluted with the proper quantity of alcohol to make spirit of nitrous ether, or they should be kept in a cool place until used. Clarence M. Kline, of Philadelphia, originated this method of protecting ethyl nitrite. Nitrous ether, or *ethyl nitrite,* is formed by the combination of nitrous acid with the radical ethyl, and its formula is $C_2H_5.NO_2$. In its pure and concentrated state it is never used in medicine. (See *Liquor Ethyl Nitritis,* p. 632.)

Properties of Spirit of Nitrous Ether.—This is "a clear, mobile, volatile and inflammable liquid of a pale yellow or faintly greenish-yellow tint, having a fragrant, ethereal, and pungent odor free from acridity, and a sharp, burning taste. When freshly prepared, or even after being kept for some time with but little exposure to light and air, it is neutral to dry litmus paper. When long kept or after having been exposed to light and air, it acquires an acid reaction. Effervescence must not result when a crystal of potassium bicarbonate is added. Specific gravity: not above 0.823 at 25° C. (77° F.). Immerse a test tube half filled with the Spirit in a water bath heated to 65° C. (149° F.) until it has acquired that temperature; the Spirit distinctly boils upon the addition of a few small pieces of broken glass. Mix 10 mils of the Spirit with 5 mils of potassium hydroxide T.S., previously diluted with 5 mils of distilled water; the mixture assumes a yellow color which does not turn decidedly brown within twelve hours (*aldehyde*)." *U. S.*

"A transparent liquid, having a very faint yellowish tinge. Peculiar penetrating apple-like odor; taste characteristic. Specific gravity 0.838 to 0.842. When Spirit of Nitrous Ether is carefully poured on an acidified strong aqueous solution of *ferrous sulphate* contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids, widening as the tube is gently shaken. Does not effervesce, or only very slightly, when shaken with *sodium bicarbonate* (limit of acid). 10 millilitres mixed with 5 millilitres of *N/1 solution of sodium hydroxide* and 5 millilitres of *water* assume a yellow color, which does not become brown on standing twelve hours (limit of aldehyde). 1 volume shaken briskly at intervals during five minutes in a brine-charged nitrometer, with 1 volume of *solution of potassium iodide* and 1 volume of *diluted sulphuric acid,* yields at 15.5° C. (60° F.) and normal pressure not less than 4 or more than 7 volumes of nitric oxide gas, corresponding to not less than 1.52 or more than 2.66 parts by weight of ethyl nitrite in 100 parts by weight of the Spirit." *Br.*

Impurities and Tests.—Spirit of nitrous ether, when made by the nitric acid process, is never quite free from aldehyde, and, if the distillation be too long continued, it is prone to contain a good deal of this substance, which afterwards becomes acetic acid by absorbing oxygen. The change goes on rapidly if the preparation be insecurely kept. Aldehyde, if in considerable proportion, may be detected by its imparting a pungent odor and an acrid flavor, and by the spirit assuming a brown tint on adding a weak solution of potassium hydroxide, owing to the formation of aldehyde resin (see official test). Another test for aldehyde, though less reliable, is the addition of an equal volume of sulphuric acid to the sweet spirit of nitre. If the sample is good, the change of color will be slight; if it contains much aldehyde, it will become dark-colored. Acetic acid, as well as other acids (usually nitrogen acids) that may happen to be present, may be discovered by the taste, by their acting on litmus strongly, and by their decomposing the alkaline carbonates or bicarbonates with effervescence. Nitrogen acids are known by their coloring blue a piece of paper previously dipped into tincture of guaiac. These acids operate injuriously by their chemical reactions with other substances, when spirit of nitre is prescribed in mixtures. Thus, they liberate iodine from potassium iodide, gradually decolorize compound infusion of rose, and in the compound mixture of iron hasten the conversion of ferrous oxide into ferric oxide. To obviate these effects, Harvey, of Leeds, keeps sweet spirit of nitre standing on crystals of potassium bicarbonate, and states that, if the preparation be of full strength, no appreciable portion of the alkali will be dissolved. (*P. J.,* Jan., 1842.) When acid sweet spirit of nitre is rectified from calcined magnesia, it becomes acid again in a short time, but, according to Klauer, when rectified from neutral potassium tartrate it continues unchanged for months. A deep olive color with

ferrous sulphate shows the presence of a nitrogen acid.

According to Bastick, sweet spirit of nitre contains about one-fifth of one per cent. of anhydrous hydrocyanic acid, when made from nitrous ether formed by acting upon alcohol with nitrous acid evolved by the action of starch on nitric acid, according to the process of Liebig. In making sweet spirit of nitre on a large scale, Squibb found that hydrocyanic acid vapors were produced if the heat happened to rise too high, and the ester ceased to be formed. Schoor and G. B. Schmidt found that, after a careful distillation, hydrocyanic acid could be detected in the residue left in the retort to the amount of 0.977 per cent., while the distillate contained but an insignificant trace. (*Ph. Ztg.*, No. 37; *N. R.*, Sept., 1880.)

Alcohol and water have often been fraudulently added to sweet spirit of nitre. These additions were at one time difficult to detect, but the official tests now afford a ready means of ascertaining its quality and strength.

The pharmacist should note specially that the U. S. P. IX requires this Spirit to be preserved in small, well-stoppered, dark, amber-colored bottles, in a cool and dark place. The former custom of keeping it in partially filled shop bottles in the regular stock must be abandoned if the preparation is to be dispensed of official strength. This is no hardship as the stock can be filled into small bottles at the time it is made and will then be ready for dispensing.

Kebler, Palkin, and Ewing in the *J. A. Ph. A.*, 1916, p. 514, record the results of many experiments conducted with a view to determining the stability of spirit of nitrous ether and the causative factors of its deterioration. They conducted twelve series of experiments covering all possible store conditions and the assays show conclusively that when properly made and carefully kept, this preparation is much more stable than is popularly supposed, and will keep much longer than the average pharmacist would keep it, without undergoing any material change.

In the *J. A. Ph. A.*, 1916, p. 1327, Englehardt and Winters suggest a new method of estimation of the ethyl nitrite, based upon Dietzes potassium chlorate method as used in the Netherland Pharmacopœia, which avoids the use of the nitrometer and barometer and gives very good results.

Uses.—Sweet spirits of nitre possesses the physiological properties of the other nitrites (see *Sodii nitris*). Its inhalation produces acceleration of the pulse with the characteristic leaden purplish color of the lips, mouth and finger tips, followed by flushing of the face, giddiness, nausea, muscular debility, and violent headache. It is rarely employed, however, to produce the full physiological action of the nitrites its chief employment being to relax the blood vessels of the skin and thereby increase the flow of sweat. It is an extremely popular diaphoretic in mild *fevers*, especially in children. Because of its action on the circulation it also at times exercises a diuretic influence.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

SPIRITUS AMMONIÆ AROMATICUS. U. S., Br.

AROMATIC SPIRIT OF AMMONIA Sp. Ammon. Arom.

(spĭr'ĭ-tŭs ăm-mō'nĭ-æ ăr-ō-măt'ĭ-cŭs)

Spiritus Ammoniæ Compositus; Spirit of Sal Volatile; Alcoolat ammoniacal aromatique, *Fr. Cod.*; Aromatischer Ammoniakgeist, *G.*

* "Ammonium Carbonate, in translucent pieces, *thirty-four grammes* [or 1 ounce av., 87 grains]; Ammonia Water, *ninety mils* [or 3 fluidounces, 21 minims]; Oil of Lemon, *ten mils* [or 162 minims]; Oil of Lavender, *one mil* [or 16 minims]; Oil of Myristica, *one mil* [or 16 minims]; Alcohol, *seven hundred mils* [or 23 fluidounces, 321 minims]; Distilled Water, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. To the ammonia water, contained in a flask, add *one hundred and forty mils* [or 4 fluidounces, 352 minims] of distilled water, and afterwards the ammonium carbonate reduced to a moderately fine powder. Close the flask and agitate the contents until the ammonium carbonate is dissolved and allow it to stand for twelve hours. Introduce the alcohol into a graduated bottle of suitable capacity, add first the oils, then gradually the solution of ammonium carbonate, and afterwards enough distilled water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Set the liquid aside during twenty-four hours in a cool place, occasionally agitating it, and then filter through paper, in a well-covered funnel. Preserve the product in glass-stoppered bottles, in a cool place." *U. S.*

"Ammonium Carbonate, 100 *grammes;* Strong Solution of Ammonia, 200 *millilitres;* Oil of Nutmeg, 15 *millilitres;* Oil of Lemon, 20 *millilitres;* Alcohol (90 per cent.), 3000 *millilitres;* Distilled Water, 1500 *millilitres*. Place the Oil of Lemon, Oil of Nutmeg, and Alcohol with the Distilled Water in a retort; distil three thousand five hundred millilitres; then distil and separately collect an additional two hundred and twenty-five millilitres. Place the latter, together with the Ammonium Carbonate and the Strong Solution of Ammonia, in a bottle holding rather more than five hundred millilitres; securely cork the bottle and gently warm it in a water-bath to 60° C. (140° F.), shaking from time to time until all the salt has dissolved. Filter the resulting solution when cold through cotton wool, and gradually mix the filtrate with the portion first distilled." *Br.*

In both of these formulas ammonium carbonate and uncombined ammonia are used; but

they differ in the relative proportion of the materials and the mode of conducting the process. The U. S. spirit is a mere solution of the ingredients in alcohol diluted with a small proportion of water, while the British contains so much of the ingredients as may rise in distillation and be condensed with the seven pints of spirit that result. The strength of the former is definite, that of the latter more or less indefinite, as a portion of the materials must be left behind. The advantage arising from distillation, however, the avoidance of discoloration, is one which is well worth considering, although the spirit will always grow darker with age. The present preparation differs from that formerly official in the substitution of oil of myristica for oil of pimenta, it having been shown that oil of pimenta increased the tendency of the spirit to darken. Commercial oil of myristica frequently has a terebinthinate odor. Much care is needed to select for this preparation volatile oils that are fresh and of good quality. The translucent official ammonium carbonate, which is a mixture of bicarbonate and carbamate, does not dissolve in alcohol; the bicarbonate precipitates, and the carbonate, $NH_4HCO_3 + NH_4OH = (NH_4)_2CO_3 + H_2O$, dissolves. The object of the addition of free ammonia in the official process is to convert the insoluble bicarbonate into the carbamate, and it is directed that these shall be allowed to stand during *twelve hours* while this change is taking place. The effloresced ammonium carbonate of commerce having parted with some of its ammonia is a bicarbonate; hence, when it is used, unless more than the official proportion of the ammonia water be added, some of the ammonium salt will remain in the precipitate as ammonium bicarbonate.

The difficulty of precipitation which so many pharmacists complain of is thus explained. It is a useful precaution to permit the ammonium carbonate and ammonia water to remain in contact for twelve hours before diluting with the other ingredients; this will secure the entire conversion of the bicarbonate, and obviate the precipitation above noted. In addition to this, it is officially directed to set the mixed liquid aside, for twenty-four hours, before final filtration. It is officially described as "a nearly colorless liquid when freshly prepared, but gradually acquiring a yellow color. It has the pungent odor and taste of ammonia. Specific gravity: about 0.900 at 25° C. (77° F.)." *U. S.*

"A nearly colorless transparent liquid. Odor and taste pungent and ammoniacal. Specific gravity 0.888 to 0.893. 20 millilitres require for neutralisation 25.4 millilitres of *N/1 solution of sulphuric acid*, corresponding to 2.16 grammes of ammonia, NH_3, in 100 millilitres of the Spirit. When 20 millilitres are mixed with 50 millilitres of *water* and excess of *solution of barium chloride*, the mixture heated to 70° C. (158° F.), the precipitate collected, washed until free from alkali, and dissolved in 20 millilitres of *N/1 solution of hydrochloric aicd*, the solution thus obtained, after being boiled and cooled, requires for neutralisation not less than 7.2 or more than 8 millilitres of *N/1 solution of sodium hydroxide*, corresponding to not less than 2.35 or more than 2.51 grammes of acid ammonium carbonate and ammonium carbamate, calculated together as $N_3H_{11}C_2O_5$, in 100 millilitres of the Spirit." *Br.*

In handling this preparation on the large scale, copper vessels must never be used, as the preparation has a solvent effect upon the film of tarnish which is always present and thereby becomes contaminated, sometimes with the development of a bright green color. When this occurs, the preparation must either be thrown away or redistilled in a glass apparatus.

Uses.—Aromatic spirits of ammonia is much more widely used than the simple spirit because of its grateful taste and odor. It is used to correct *hyperacidity of the stomach* when not associated with inflammatory changes in the mucous membrane of that organ, and especially when there is *nausea* or *sick headache*. By virtue of its local irritant effect upon the mucous membrane of the stomach it will often reflexly excite the medulla and thereby relieve the feeling of *faintness*. It has, however, been enormously misapplied as a heart stimulant; as pointed out elsewhere (see *Aqua Ammoniæ*) although ammonia is a stimulant to the circulation it can act only when injected hypodermically.

Dose, thirty minims to a fluidrachm (1.8–3.75 mils), sufficiently diluted.

Off. Prep.—Mistura Sennæ Composita, *Br.;* Tinctura Guaiaci Ammoniata, *U. S.;* Tinctura Valerianæ Ammoniata, *U. S.;* Liquor Sodæ et Menthæ, *N. F.;* Tinctura Kino et Opii Composita, *N. F.*

SPIRITUS AMMONIÆ FŒTIDUS. Br.

FETID SPIRIT OF AMMONIA

(spĭr'ĭ-tŭs ăm-mō'nĭ-æ fœt'ĭ-dŭs)

Alcoolat ammoniacal fétide, Essence antihystérique, *Fr.;* Ammoniakalischer Stinkasantgeist, *G.*

"Asafetida, 75 *grammes;* Strong Solution of Ammonia, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres*. Break the Asafetida into small pieces, and macerate it in a closed vessel in seven hundred and fifty millilitres of the Alcohol for twenty-four hours; distil until alcoholic vapors cease to be condensed; mix the distillate with the Strong Solution of Ammonia, and add sufficient Alcohol to produce the required volume." *Br.*

This is an alcoholic solution of the volatile oil of asafetida mixed with strong solution of ammonia, and is an energetic nervous stimulant and antacid, adapted to certain *hysterical conditions* associated with gastric weakness and acidity. It is one of the preparations formerly recognized by the British Colleges, and reinstated after having been dropped from the first British Pharmacopœia.

"A nearly colorless, transparent liquid with a strong odor of ammonia and of asafetida. Specific gravity 0.842 to 0.850. 25 millilitres require for neutralisation not less than 40 milli-

litres of *N/1 solution of sulphuric acid,* corresponding to not less than 2.72 grammes of ammonia, NH_3, in 100 millilitres of the Spirit." *Br.*

This preparation combines the carminative effect of asafetida with the antacid properties of ammonia. It may be used in gastric or intestinal *flatulence.*

Dose, thirty minims to a fluidrachm (1.8–3.75 mils), to be largely diluted when administered.

SPIRITUS AMYGDALÆ AMARÆ. U. S.

SPIRIT OF BITTER ALMOND Sp. Amygd. Amar.
[Essence of Bitter Almond]

(spĭr'ĭ-tŭs ą-mŷg'dą-læ ą-mā'ræ)

Alcoolé d'essence amande amere, *Fr.;* Bittermandelgeist, *G.*

* "Oil of Bitter Almond, *ten mils* [or 162 minims]; Alcohol, *eight hundred mils* [or 27 fluidounces, 24 minims]; Distilled Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the oil in the alcohol, and add enough distilled water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Note: This Spirit is intended for medicinal use; it must not be used for flavoring foods." *U. S.*

Although the U. S. P. states that "this spirit is intended for medicinal use; it must not be used for flavoring foods," *U. S.,* it has little medicinal virtue except for its flavor. Because of the hydrocyanic acid in the oil of bitter almond this preparation will contain approximately 0.03 per cent. of that acid and hence cannot be used incautiously. It would have been better to have replaced this spirit with a solution of benzaldehyde.

Dose, from two to eight minims (0.12–0.5 mil).

Off. Prep.—Elixir Anisi, *N. F.*

SPIRITUS ANISI. U. S., Br.

SPIRIT OF ANISE Sp. Anisi

(spĭr'ĭ-tŭs ą-nī'sī)

Essence of Anise; Teinture d'essence d'anis vert, *Fr. Cod.;* Anisgeist, *G.*

* "Oil of Anise, *one hundred mils* [or 3 fluidounces, 183 minims]; Alcohol, *a sufficient quantity* to make *one thousand mils* [or 33 fluidounces 6½ fluidrachms]. Mix the oil with sufficient alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.* "Oil of Anise, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

Dose, as a stomachic and carminative, from twenty to sixty minims (1.3–3.75 mils), properly diluted.

SPIRITUS ARMORACIÆ COMPOSITUS. Br.

COMPOUND SPIRIT OF HORSERADISH

(spĭr'ĭ-tŭs ăr-mǫ-rā'cĭ-æ cǫm-pŏs'ĭ-tŭs)

Esprit (alcoolat) de Raifort composée, Alcoolat antiscorbutique, *Fr.;* Zusammengesetzter Meerrettiggeist, *G.*

"Horseradish Root, scraped, 125 *grammes;* Dried Bitter-Orange Peel, bruised, 125 *grammes;* Nutmeg, bruised, 3 *grammes;* Alcohol (90 per cent.), 625 *millilitres;* Distilled Water, 750 *millilitres.* Macerate the Horseradish Root in the Distilled Water for one hour, add the other ingredients, and distil one thousand millilitres. Specific gravity 0.917 to 0.927." *Br.*

This may be used advantageously as an addition to diuretic remedies, in *dropsy* attended with debility, especially in the case of drunkards.

Dose, from one to four fluidrachms (3.75–15 mils).

SPIRITUS AURANTII COMPOSITUS. U. S.

COMPOUND SPIRIT OF ORANGE Sp. Aur. Co.

(spĭr'ĭ-tŭs âu-răn'tĭ-ī cǫm-pŏs'ĭ-tŭs)

Teinture d'essence d'orange, *Fr. Cod.;* Esprit d'orange composée, *Fr.;* Zusammengesetzter Orangegeist, *G.*

* "Oil of Orange, *two hundred mils* [or 6 fluidounces, 366 minims]; Oil of Lemon, *fifty mils* [or 1 fluidounce, 331 minims]; Oil of Coriander, *twenty mils* [or 325 minims]; Oil of Anise, *five mils* [or 81 minims]; Alcohol, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix them. Keep the product in completely filled, well-stoppered bottles, in a cool and dark place." *U. S.*

This compound spirit has been introduced for the purpose of producing the orange flavor in making the official aromatic elixir (page 411), and in various N. F. elixirs. It will be found by physicians to be a useful and fragrant addition to prescriptions.

Off. Prep.—Elixir Aromaticum, *U. S.*

SPIRITUS CAJUPUTI. Br.

SPIRIT OF CAJUPUT

(spĭr'ĭ-tŭs căj-ŭ-pū'tī)

Teinture (alcoolé) d'essence de Cajeput, Alcoolé d'essence de Cajeput, *Fr.;* Cajeputgeist, *G.*

"Oil of Cajuput, 100 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

For an account of the medicinal properties and uses of oil of cajuput, of which this is simply an alcoholic solution, see *Oleum Cajuputi.*

Dose, from five to twenty minims (0.3–1.3 mils), properly diluted.

SPIRITUS CAMPHORÆ. U. S., Br.

SPIRIT OF CAMPHOR Sp. Camph.

(spĭr'ĭ-tŭs căm'phǫ-ræ)

"*One hundred mils* of Spirit of Camphor yields not less than 9.5 Gm. nor more than 10.5 Gm. of camphor." *U. S.*

Tinctura Camphoræ, *U. S.* 1850; Tincture of Camphor; Alcohol Camphoratus; Teinture de camphre concentrée, *Fr. Cod.;* Esprit de Camphre, Alcool camphré, *Fr.;* Spiritus Camphoratus, *P. G.;* Kamphergeist, *G.*

* "Camphor, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity,* to make *one thousand mils* [or 33

fluidounces, 6½ fluidrachms]. Dissolve the camphor in *eight hundred mils* [or 27 fluidounces, 24 minims] of alcohol, filter through paper, and pass enough alcohol through the filter to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Camphor, 100 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. Specific gravity, 0.845 to 0.850. *Optical rotation* at 15.5° C. (60° F.), not less than + 4°." *Br.*

"Add 0.05 Gm. of anhydrous potassium carbonate to 5 mils of Spirit of Camphor; the potassium carbonate does not liquefy or adhere to the bottom of the vessel (*added water*).

"**Assay.**—Fill a two hundred millimeter polariscope tube with the Spirit of Camphor and take the mean of four or more readings of the rotation, beginning at zero each time. The temperature correction for each degree is half a minute, additive if above, subtractive if below, 25° C. (77° F.). Evaporate 60 mils of the Spirit of Camphor in a dish, on a water bath, and when the camphor begins to solidify stir it with a glass rod until dry. Then transfer the camphor to a watch glass, cover it with an inverted funnel and place the watch glass on wire gauze 10 cm. above a Bunsen burner having a flame 4 cm. high. When the camphor has all sublimed, dissolve 2.5 Gm. of the sublimate in sufficient alcohol (which must be of about 95 per cent. by volume) to make exactly 25 mils and take the mean of four or more polariscope readings as before. The minutes of rotation of the Spirit of Camphor divided by the minutes of rotation of the control test just made, and this multiplied by 10, shows the number of grammes of camphor in 100 mils of the Spirit of Camphor." *U. S.*

For another method of assay of spirit of camphor, see *Ph. Centralh.*, 1901, 472.

The camphor content of the spirit is easily obtained by the official method when a polariscope is available, but the detection of the addition of water is a more difficult task. This has been worked out by Maiden and Elliot, and the results of the method published in the *J.A. Ph. A.*, 1914, p. 91.

Spirit of camphor is an excellent preparation, much used locally in liniments and internally in *diarrhea,* and in *hysteria* and other forms of *nervous excitement.* Dilution with water precipitates the camphor, but when as in many cases it is desired to combine it with aqueous preparations, by dropping it into brandy or whisky and then adding water an eligible preparation is obtained; or the spirit of camphor may be dropped upon sugar and then mixed with water.

Dose, from ten to thirty minims (0.6–1.8 mils).

Off. Prep.—Lotio Ammoniacalis Camphorata, *N. F.;* Mistura Opii et Chloroformi Composita, *N. F.;* Mistura Opii et Rhei Composita, *N. F.;* Tinctura Kino et Opii Composita, *N. F.;* Tinctura Pectoralis, *N. F.*

SPIRITUS CHLOROFORMI. U. S., Br.

SPIRIT OF CHLOROFORM Sp. Chlorof.

(spĭr'ĭ-tŭs ċhlō-rō-för'mī)

Chloric Ether, Spirit of Chloric Ether, *Br.;* Alcoolé de Chloroforme, *Fr.;* Chloroformspiritus, *G.*

* "Chloroform, *sixty mils* [or 2 fluidounces, 14 minims]; Alcohol, *a sufficient quantity* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the chloroform with sufficient alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.* "Chloroform, 50 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve." *Br.*

It is to be regretted that the name Chloric Ether has been retained as a synonym in the British Pharmacopœia, 1914. There would be some reason for naming a mixture of chloroform and ether by the title chloric ether, but to use the term for an alcoholic solution of chloroform must inevitably cause confusion.

Chloric ether of the older works was a solution of variable strength of chloroform in alcohol, and was used as a general anesthetic. The practice has, however, very properly been abandoned, and the spirit of chloroform is now used as an internal remedy, especially in cases of *gastro-intestinal spasm* or *pain,* in which it acts as a local agent. The official aromatic elixir is an agreeable vehicle for its administration.

Dose, from ten to sixty minims (0.6–3.75 mils).

SPIRITUS CINNAMOMI. U. S., Br.

SPIRIT OF CINNAMON Sp. Cinnam.

(spĭr'ĭ-tŭs cĭn-nạ-mō'mī)

Teinture (alcoolé) d'essence de Cannelle, Esprit de Cannelle, *Fr.;* Zimmtspiritus, *G.;* Spirito di cannella, *It.*

* "Oil of Cinnamon, *one hundred mils* [or 3 fluidounces, 183 minims]; Alcohol, *a sufficient quantity* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the oil with sufficient alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Oil of Cinnamon, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

The spirit of cinnamon is an agreeable aromatic cordial.

Dose, from ten to thirty minims (0.6–1.8 mils) in water.

SPIRITUS GLYCERYLIS NITRATIS. U. S. (Br.)

SPIRIT OF GLYCERYL TRINITRATE, SPIRIT OF NITROGLYCERIN Sp. Glyceryl. Nit.

[Spiritus Glonoini, U. S. 1890, Spirit of Glonoin]

(spĭr'ĭ-tŭs glĭċ-ẹ-rĭ'lĭs nī-trā'tĭs)

"An alcoholic solution containing not less than 1 per cent. nor more than 1.1 per cent. of $C_3H_5(NO_3)_3$ (227.07). Preserve it in well-stoppered bottles in a cool, dark place, remote from fire.

Great care must be exercised in dispensing, handling, packing, transporting, and storing this Spirit, since a dangerous explosion may result if any considerable quantity of it is spilled, and the alcohol wholly or partly lost by evaporation. If, through accident, it is spilled, a solution of potassium hydroxide must be poured over it at once to effect partial decomposition." *U. S.*

Liquor Trinitrini, *Br.*; Solution of Trinitrin; Liquor Nitroglycerini; Solution of Nitroglycerin; Liquor Glonoini; Solution of Glonoin; Nitroglyceringeist, Glycerintrinitratlösung, *G.*

"Trinitroglycerin of commerce, 1 *gramme;* Alcohol (90 per cent.), sufficient to produce 100 *millilitres.* Dissolve." *Br.*

This official spirit was first introduced into the U. S. P. 1890 with the view of furnishing a satisfactory form for the administration of nitroglycerin.

The British Liquor Trinitrini is practically identical. Abundant precautions are included, which should on no account be neglected. The official description is as follows: "A clear, colorless liquid, having the odor of alcohol. *Caution must be exercised in tasting it,* since even a small quantity is liable to produce a violent headache. The same effect is produced when it is applied to the skin. It is neutral to litmus. Specific gravity: 0.814 to 0.820 at 25° C. (77° F.). Heat about 10 mils of Spirit of Glyceryl Trinitrate on a water bath with 1 mil of potassium hydroxide T.S. until the alcohol is evaporated, and then heat a portion of the residue with about 0.5 Gm. of potassium bisulphate; the pungent odor of acrolein is evolved. Dissolve the remainder of the residue in 2 mils of distilled water acidulated with diluted sulphuric acid, add a few drops of diphenylamine T.S. and pour the solution upon 2 mils of sulphuric acid in a test tube so as to form a separate layer; a dark blue color is produced at the zone of contact. Mix 10 mils of the Spirit with 11 mils of distilled water, both previously cooled to 15° C. (59° F.); a clear solution results. On now adding 2 mils more of distilled water, the mixture, at 15° C. (59° F.), becomes turbid. Weigh accurately not more than about 5 mils of the Spirit, allow it to evaporate spontaneously in a tared dish protected from dust, and dry the residue to constant weight in a desiccator, over sulphuric acid. The weight of the residue corresponds to not less than 1 per cent. nor more than 1.1 per cent. of the weight of Spirit taken." *U. S.*

"A clear colorless liquid, neutral to *litmus.* Specific gravity 0.840. A mixture of 10 millilitres with an equal volume of *water,* cooled to 15.5° C. (60° F.), remains clear, but the further admixture of 1 millilitre of *water* causes opacity (presence of a due amount of glyceryl trinitrate). On further diluting with *water* and setting aside the mixture, there is deposited a liquid of oily consistence, one drop of which, absorbed by paper and struck with a hammer on a hard surface, explodes. This Solution contains 1 gramme of trinitroglycerin in 100 millilitres; 110 minims contain 1 grain." *Br.*

For a method of assaying this spirit, by Chas. Rice, see *Am. Drug.,* 1895, 6; also Nagelvoort's method, *A. J. P.,* 1894, 527. F. W. Heyl and J. F. Staley review the various methods for the estimation of nitroglycerin and give comparative results of the assay of a large number of preparations and tablets. (*A. J. P.,* 1914, p. 195.) On account of the importance of nitroglycerin as a therapeutic agent, we append the following:

Nitroglycerin. Trinitrine. Glonoin. Glyceryl Trinitrate. $C_3H_5(NO_3)_3$.—When glycerin is gradually added in small portions at a time to a mixture of one part of strong nitric acid and three to four parts of concentrated sulphuric acid, and at a temperature kept low by artificial refrigeration, it is converted into a bright yellow liquid, which has remarkable explosive properties and has received the name at the head of this article. Nitroglycerin was discovered in the year 1846 by Sobrero of Turin, who called it *pyroglycerine.* It was afterwards made a subject of study by de Vrij of the Netherlands, Gladstone, and Kopp, but did not attract general attention until 1867, when Alfred Nobel, a Swedish engineer, suggested its use for explosive purposes by mixing it with inert substances like kieselguhr or infusorial earth to make the product commercially known as *dynamite.* It is a yellow liquid (said to be colorless or slightly yellowish when pure); of a sp. gr. from 1.525 to 1.6; inodorous; of a sweet, pungent, aromatic taste; very slightly soluble in water, but readily soluble in ether, alcohol, and methylated spirit; not freezing above −15.5° C. (4° F.) when quite pure, according to J. R. Wagner, but, as it occurs in commerce, solidifying by continued exposure to a temperature of 8° C. (46.4° F.), and assuming the form of long needles, which it is dangerous to handle, as they explode violently when gently broken. In the liquid state the mere contact of flame does not inflame or explode it; but concussion, or touching it with a red-hot iron, explodes it with great vehemence. Detonating mixtures, or exploding gunpowder, in its near vicinity, produce the same effect. By keeping, it undergoes partial decomposition, and in confined vessels the pressure of the accumulated gases which result is sometimes so great as to cause its explosion upon the slightest concussion. Its explosive force greatly exceeds that of gunpowder. According to Nobel, one volume of the fluid yields on explosion 10,384 volumes of gas, while one volume of gunpowder yields only 800 volumes. It has, therefore, been much employed in blasting rocks, in mining, quarrying, road making, etc., and its economical advantages have kept it in extensive use, notwithstanding the danger.

Nitroglycerin is formed by the introduction of the nitro-group (NO_3) in place of the three replaceable hydrogen atoms of the glycerin formula, according to the reaction:

$$C_3H_5(OH)_3 + 3(HNO_3) = C_3H_5.(NO_3)_3 + 3(H_2O)$$

E. Kopp gives the following as his method of

preparing nitroglycerin on the spot where it is needed. First, fuming nitric acid of the sp. gr. 1.51 to 1.53 is mixed with twice its weight of the strongest sulphuric acid. At the same time commercial glycerin, free from lead and lime, is evaporated in a pot to 30° or 31° Baumé, so that on cooling it shall have a syrupy consistence. Into 3300 grammes of the acid mixture, contained in a glass or porcelain capsule placed in a trough of cold water, 500 grammes of the prepared glycerin are slowly poured with constant stirring, great care being taken to prevent any sensible heating of the mixture. The whole is then to be left for five or ten minutes, after which the mixture is to be poured into five or six times its volume of cold water to which a rotatory motion has been given. The nitroglycerin precipitates rapidly in the form of a heavy liquid, which is separated by decantation, then washed with a little alkaline water which is decanted; it is then put into bottles. In this state it still contains a little acid and water, but these do not interfere with its use as an explosive agent if it is promptly used. Latterly it has also been prepared by mixing 3½ parts of sulphuric acid of 1.83 sp. gr. with 1 part of potassium nitrate, and cooling this, when potassium sulphate will crystallize out. The acid drained off from this is peculiarly adapted for the formation of nitroglycerin, which then takes place rapidly and without so much dangerous development of heat.

The sulphuric acid plays no part in the reaction and acts simply as a dehydrating agent. Nitroglycerin, being an ester, is readily saponified and rendered harmless when brought into contact with alkali hydroxides even in the cold. The reaction is as follows: $C_3H_5(NO_3)_3 + 3KOH = C_3H_5(OH)_3 + 3KNO_3$.

A complete and well illustrated article on nitroglycerin manufacture will be found in Molinari's Industrial Organic Chemistry, p. 223.

Uses.—The effects of nitroglycerin upon the system are precisely similar to those of the nitrites (see *Sodii Nitris*). According to the observations of Wallace and Ringer (*J. A. M. A.*, 1909, lii, p. 1629) the effects of one and one-half minims of the spirits of nitroglycerin come on within two or three minutes after taking by the mouth and endure for about one-half hour. The amount of the drug required to affect the system varies extraordinarily in different individuals. Murrell (*L. L.*, 1879, i, p. 80), has reported violent effects from one or two minims of the 1 per cent. solution. On the other hand, Kolipinski (*M. News*, 1890) reports a case in which two drachms of the official solution were taken without serious symptoms (amount somewhat doubtful). It is probable that many of these cases in which large quantities have been ingested the drug was of inferior quality. Nitroglycerin is a volatile substance and unless evaporation is guarded against its preparations lose potency. The tablet triturates of nitroglycerin which are frequently employed, are especially liable to deterioration. The spirit of glyceryl nitrate is used in the same class of cases as sodium nitrite, but is employed where rapidity of action is important, as in *angina pectoris, threatened apoplexy, asthma, strychnine poisoning,* and the like. It has been enormously misused as a cardiac stimulant in various forms of collapse; it should be remembered that its effect is always to lower blood pressure and it can do no good in any form of circulatory failure. It has been highly recommended in *hemoptysis,* its action being attributable to the consentaneous dilatation of the abdominal and contraction of the pulmonary vessels.

According to Ebright (*J. A. M. A.*, 1914, lxii, p. 201), workers in dynamite factories are subject to chronic nitroglycerin poisoning. The most characteristic symptom of this intoxication is throbbing headache, at times so violent that the patient may become maniacal. The pain is made worse by lying down and is not alleviated by either acetphenetidin or morphine. After some time the workers in these factories appear to develop an immunity to the poisoning.

Dose, of the spirit, from one to two minims (0.06–0.12 mil).

SPIRITUS JUNIPERI. U. S., Br.

SPIRIT OF JUNIPER Sp. Junip.

(spĭr'ĭ-tŭs jū-nĭp'ẹ-rī)

Teinture d'essence de Genièvre, *Fr. Cod.*; Spiritus Juniperi, *P. G.*; Wachholderspiritus, *G.*

* "Oil of Juniper, *fifty mils* [or 1 fluidounce, 331 minims]; Alcohol, *a sufficient quantity* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the oil with sufficient alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Oil of Juniper, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter. This Spirit is of twice the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This spirit is used chiefly as an addition to diuretic infusions. It is about 33 per cent. stronger than the spirit official before 1890.

Dose, from thirty to sixty minims (1.8–3.75 mils).

SPIRITUS JUNIPERI COMPOSITUS. U. S.

COMPOUND SPIRIT OF JUNIPER Sp. Junip. Co.

(spĭr'ĭ-tŭs jū-nĭp'ẹ-rī cọm-pŏs'ĭ-tŭs)

Teinture (alcoolé) d'essence de Genièvre composée, *Fr.*; Zusammengesetzter Wachholderspiritus, *G.*

* "Oil of Juniper, *eight mils* [or 130 minims]; Oil of Caraway, *one mil* [or 16 minims]; Oil of Fennel, *one mil* [or 16 minims]; Alcohol, *fourteen hundred mils* [or 47 fluidounces, 162 minims]; Water, *a sufficient quantity,* to make *two thousand mils* [or 67 fluidounces, 301 minims]. Dissolve the oils in the alcohol, and gradually add enough water to make the product measure *two thousand mils* [or 67 fluidounces, 301 minims]." *U. S.*

This spirit is a useful addition to diuretic in-

fusions and mixtures in debilitated cases of *dropsy*. It corresponds very closely to Holland gin.

Dose, from two to four fluidrachms (7.5–15 mils).

SPIRITUS LAVANDULÆ. U. S., Br.

SPIRIT OF LAVENDER Sp. Lavand.

(spĭr'ĭ-tŭs lą-văn'dŭ-læ)

Teinture (alcoolé) d'essence de Lavande, *Fr.*; Spiritus Lavandulæ, *P. G.*; Lavandelspiritus, *G.*

* "Oil of Lavender, *fifty mils* [or 1 fluidounce, 331 minims]; Alcohol, *a sufficient quantity* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the oil with sufficient alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Oil of Lavender, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

Spirit of lavender is used widely as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Brande as one of the most approved recipes for preparing it. "Take of rectified spirit five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* [made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol] half an ounce. Mix." The Br. spirit is double the strength of the U. S. preparation. It is a grateful stimulant and carminative when administered in sweetened water.

Dose, of the U. S. Spirit, from ten to thirty minims (0.6–1.8 mils); of the Br. Spirit, five to twenty minims (0.3–1.3 mils).

Off. Prep.—Mistura Ferri Composita, *N. F.*

SPIRITUS MENTHÆ PIPERITÆ. U. S., Br.

SPIRIT OF PEPPERMINT Sp. Menth. Pip. [Essence of Peppermint]

(spĭr'ĭ-tŭs mĕn'thæ pĭp-ẹ-rĭ'tæ)

Teinture d'essence de Menthe, *Fr. Cod.*; Spiritus Menthæ Piperitæ, *P. G.*; Pfefferminzspiritus, Englische Pfefferminzessenz, *G.*; Alcohol de menta piperita, *Sp.*

* "Oil of Peppermint, *one hundred mils* [or 3 fluidounces, 183 minims]; Peppermint, bruised, *ten grammes* [or 154 grains]; Alcohol, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Macerate the peppermint leaves, freed as much as possible from stems, during one hour in *five hundred mils* [or 16 fluidounces, 435 minims] of water and then strongly express them. Mix *eight hundred mils* [or 27 fluidounces, 24 minims] of alcohol with the oil, add the macerated leaves and enough alcohol to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], macerate the mixture during six hours, with frequent agitation, and then filter it. Preserve the product in amber-colored bottles." *U. S.*

"Oil of Peppermint, 100 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

The distilled spirit has no advantage over a simple solution of the oil in alcohol; and this mode of preparing it has been adopted both in the U. S. and British Pharmacopœias. The American spirit is green in color, but the British is almost colorless. P. H. Utech suggests the maceration of the peppermint in water for two hours, washing and draining, before adding to the solution of the oil; water soluble matter is removed and a more permanent green color produced. He recommends the same treatment for the spearmint in making spirit of spearmint, and the U. S. P. IX adopted this plan. It has long been popularly used under the name of *essence of peppermint.* The spirit of peppermint affords a convenient method of administering a dose of the volatile oil, being of such a strength that when dropped on loaf-sugar it may be taken without inconvenience.

Dose, ten to thirty minims (0.6–1.8 mils), given as just mentioned, or mixed with sweetened water.

SPIRITUS MENTHÆ VIRIDIS. U. S.

SPIRIT OF SPEARMINT Sp. Menth. Vir.

(spĭr'ĭ-tŭs mĕn'thæ vīr'ĭ-dĭs)

Tinctura Olei Menthæ Viridis, *U. S.* 1850; Essence of Spearmint; Grüne Minzessenz, *G.*

* "Oil of Spearmint, *one hundred mils* [or 3 fluidounces, 183 minims]; Spearmint, bruised, *ten grammes* [or 154 grains]; Alcohol, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Macerate the spearmint leaves, freed as much as possible from stems, during one hour in *five hundred mils* [or 16 fluidounces, 435 minims] of water and then strongly express them. Mix *eight hundred mils* [or 27 fluidounces, 24 minims] of alcohol with the oil, add the macerated leaves and enough alcohol to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], macerate the mixture during six hours, with frequent agitation, and then filter it. Preserve the product in amber-colored bottles." *U. S.*

The remarks made on the Spirit of Peppermint are equally applicable here.

Dose, ten to thirty minims (0.6–1.8 mils).

SPIRITUS MYRISTICÆ. Br.

SPIRIT OF NUTMEG [Essence of Nutmeg]

(spĭr'ĭ-tŭs mў-rĭs'tĭ-cæ)

Teinture (alcoolé) d'essence de Muscade, *Fr.*; Muskatspiritus, *G.*

"Oil of Nutmeg, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

It is used chiefly for its flavor. Spirit of nutmeg was not retained in the U. S. P. IX. It was made in the U. S. P., 1890, by dissolving 50 mils of nutmeg in 950 mils of alcohol. (See *Oleum Myristicæ.*)

Dose, from five to twenty minims (0.3–1.3 mils).

SPIRITUS RECTIFICATUS. Br.

ALCOHOL (90 PER CENT.) [Rectified Spirit]

(spĭr'ĭ-tŭs rĕc-tĭ-fĭ-cā'tŭs)

"Alcohol (90 per cent.) is a mixture of ethyl hydroxide and water, containing in 100 parts by volume 90 parts by volume of ethyl hydroxide, C_2H_5OH; and is obtained by the distillation of fermented saccharine liquids." *Br.*

"A colorless, transparent, very mobile and inflammable liquid. Characteristic pleasant odor; taste strongly spirituous, burning. Specific gravity 0.8337. Contains 85.68 per cent. by weight of ethyl hydroxide, C_2H_5OH, and 14.32 per cent. by weight of water. Burns with a blue smokeless flame. Leaves no residue on evaporation (absence of non-volatile matter). Remains clear when mixed with *water* (absence of oily or resinous substances). A little exposed on clean white filter paper leaves no unpleasant smell after the alcohol has evaporated (absence of fusel oil and allied impurities). 100 millilitres, with 2 millilitres of *N/10 solution of silver nitrate,* exposed for twenty-four hours to bright light and then decanted from the black powder which has formed, undergo no further change when again exposed to light with more *N/10 solution of silver nitrate* (absence of more than traces of amylic alcohol and of other organic impurities). When mixed with half its volume of an aqueous solution (1 in 5) of *sodium hydroxide,* the mixture does not immediately darken in color (absence of more than traces of aldehyde). No immediate darkening in color is caused by the addition of *solution of ammonia* (absence of tannin, excess of aldehyde, and other organic impurities). On mixing Alcohol (90 per cent.) and *water,* contraction of volume and rise of temperature occur. When such a mixture is prescribed in the British Pharmacopœia, the cooled liquid should be employed." *Br.*

For further information concerning this liquid, the reader is referred to *Alcohol,* page 103, and also to the text under the article *Alcohol Dilutum,* page 104.

SPIRITUS ROSMARINI. Br.

SPIRIT OF ROSEMARY

(spĭr'ĭ-tŭs rŏs-mą-rī'nī)

Spiritus Anthos; Teinture d'essence de Romarin, *Fr. Cod.;* Rosmarinspiritus, *G.;* Alcohol de romero, *Sp.*

"Oil of Rosemary, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

This spirit is not official in the United States Pharmacopœia IX. It is a grateful perfume, and is used chiefly as an odorous ingredient in lotions and liniments.

STAPHISAGRIA. U. S. (Br.)

STAPHISAGRIA Staphisag. [Stavesacre]

(stăph-ĭ-sā'grĭ-ą)

"The ripe seeds of *Delphinium Staphisagria* Linné (Fam. *Ranunculaceæ*), without the presence or admixture of more than 2 per cent. of foreign vegetable matter." *U. S.* "Stavesacre Seeds are the dried ripe seeds of Delphinium Staphisagria, *Linn.*" *Br.*

Staphisagriæ Semina, *Br.;* Semen Staphisagriæ, Staphidiagriæ or Pedicularis; Stavesacre Seeds; Staphisaigre, *Fr. Cod.;* Stephanskörner, Läusekörner, *G.;* Stafisagria, *It.*

Delphinium Staphisagria L., or stavesacre, is a handsome, annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five- or seven-lobed leaves, supported on hairy petioles. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The sepals are five in number, irregular, petal-like, the upper one being spurred at the base. The petals are four, irregular, the two upper having long spurs which are inclosed in the spur of the calyx, the two lower having short claws. The pistils form a many seeded pod or capsule in fruit.

The plant is a native of the south of Europe. E. M. Holmes calls attention to the remarkable fact that the plant in the English botanic gardens hitherto considered to be *Delphinium Staphisagria* is in reality another species, *i.e., Delphinium pictum* Willd. The author accounts for the absence of the true plant in botanic gardens partly by the fact that it is only half-hardy in Great Britain, while *D. pictum* is hardy, and partly by the reason that the illustrations in several works on medicinal plants—even in Bentley and Trimen's "Medicinal Plants"—are incorrect or unreliable. The two species are distinguished as follows: *D. Staphisagria* has very hairy stems, glandular hairs being mixed with the long spreading soft hairs; flowers that when well-developed have an ultramarine blue tint; a calyx with very short or almost obsolete spur; carpels containing only four or five seeds. *D. pictum* Willd., has shorter soft hairs, but no glandular hairs on the stems; the flowers are of a pale lilac color; the spur is as long as the calyx segments; each carpel contains ten or twelve seeds, and these are only half the size of those of *D. Staphisagria.* The true *D. Staphisagria* extends from Teneriffe around both the northern and southern coasts of the Mediterranean to Asia Minor. It is quite possible, therefore, that varieties having blossoms of different tints may occur. The evidence obtainable, however, goes to show that the form of the plant from which the seed of commerce is obtained has clear blue flowers. (*Y. B. P.,* 1899, 390.) For description of other species of this genus, see *Delphinium,* Part II.

Properties.—The seeds of stavesacre are officially described as "irregularly triangular, flattened, or somewhat tetrahedral, one side being convex, from 4 to 7 mm. in length and from 3 to 6 mm. in breadth; externally dark brown, becoming lighter with age, and coarsely reticulate; easily cut, showing a somewhat light brown, oily endosperm, enclosing a small embryo at the pointed end; odor slight, disagreeable; taste intensely bitter and acrid. Under the microscope, transverse sections of Staphisagria show an outer layer of nearly tabular, thick-walled, non-lignified cells, some being extended centrifugally, and forming the reticulations of the seed-coat; 2 or 3 rows of parenchyma cells with more or less irregular thin walls; a thin layer of very small, thick-walled cells with numerous, lattice-like or reticulate pores; endosperm large, composed of polygonal cells enclosing small aleurone grains and fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S." *U. S.*

"Irregularly triangular or obscurely quadrangular, arched, blackish-brown when fresh, but becoming dull greyish-brown on keeping. Surface wrinkled and deeply pitted; kernel soft, whitish, oily. No marked odor; taste nauseous, bitter and acrid." *Br.*

The seeds of the field larkspur (*D. Consolida* L.) and of *D. Ajacis* L. are being largely used in place of the official staphisagria; in fact, they are recognized in the National Formulary. These are readily distinguished, being about 2 mm. in length and of a black or blackish-brown color.

The virtues of staphisagria are extracted by water and alcohol. Analyzed by Lassaigne and Feneulle it yielded a brown and a yellow bitter principle, a volatile oil, about 30 per cent. of a fixed oil, albumen, a nitrogenous substance, a mucilaginous saccharine matter, mineral salts, and a peculiar alkaloid called *delphinine,* which exists in the seeds combined with an excess of malic acid. Marquis, in Dragendorff's laboratory in 1877, isolated the following four alkaloids: *delphinine,* $C_{22}H_{35}O_6N$, a crystallizable alkaloid, of bitter taste, weak alkaline reaction, soluble in alcohol, ether, and chloroform; *delphinoidine,* $C_{42}H_{68}O_7N_2$, amorphous, soluble in ether, alcohol, chloroform, reaction strongly alkaline, fusing point from 110° to 120° C. (230°–248° F.); *delphisine,* $C_{27}H_{46}O_4N_2$, crystallizing in warty aggregations, soluble in ether, alcohol, and chloroform; *staphisagrine,* $C_{22}H_{33}O_5N$, only obtained amorphous, difficultly soluble in water and ether, easily soluble in alcohol and chloroform, of bitter taste, fusing point 90° C. (194° F.), of alkaline reaction in alcoholic solution. If delphinine be rubbed up with an equal quantity of malic acid, and some drops of concentrated sulphuric acid added, there will be produced an orange-red color passing into rose, growing deeper after some hours, and finally changing from the edges to violet, and at last becoming cobalt blue. (Tattersall, *Chem. News,* 41.) It is stated that no other alkaloid and no other organic acid, except malic, affords this reaction. (*Pflanzenstoffe,* 2d ed., 1884, 617.) The total amount of alkaloids is about 1 per cent. According to Charalampi Kara-Stojanow (*In. Dis.,* Dorpat, 1890), delphinine and *delphisine* have the same composition, $C_{31}H_{49}O_7N$, crystallize from their solutions in ether and petroleum benzin in identical forms, and have their melting points at 189° and 191° C. (372.2° and 375.8° F.), while *delphinoidine* has the formula $C_{25}H_{12}O_4N$. Ahrens (*Ap. Ztg.,* 1899, 361) obtained from the residue of the seeds of *D. staphisagria,* from which delphinine, delphinoidine, delphisine and staphisagrine had been extracted, the alkaloid *staphisagroine* (*Ber. d. Chem. Ges.,* 1899, 1581). For Katz's process for extracting delphinine, see *Ph. Ztg.,* 1900, 735.

Uses.—The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of their violence. A strong tincture has been employed as an embrocation in *rheumatism.* The ointment is used to destroy *lice* and the *itch-mite.* Staphisagria should never be used internally, and when it is applied externally, care should be exercised not to put it on an abraded surface, but only upon the unbroken epidermis. In some countries the seeds are used like Cocculus Indicus to intoxicate fish.

When given in poisonous doses to the lower animals, *delphinine* produces excessive salivation, followed by violent and repeated vomiting, great disturbance of respiration, failure of heart action, gradual enfeeblement of voluntary motion and of sensation, and a peculiar fibrillary spasm of the muscles of the abdomen, which is said to be characteristic of the poisoning. Elevation of temperature and glycosuria have both been noticed; death is said to occur always from failure of respiration, though the heart is greatly enfeebled and finally ceases in diastole. According to Gauthier, the period of depression of the heart and of sensibility is preceded by one of excitement. The pupils are dilated and the motor nerve finally paralyzed. (*L. M. R.,* Oct., 1887.) Turnbull, in his work *On the Medical Properties of the Ranunculaceæ,* states that pure delphinine may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting, and without producing much intestinal irritation, though it sometimes purges. In most instances it proves diuretic, and gives rise to sensations of heat and tingling in various parts of the body. Externally, it acts like veratrine, but, according to Turnbull, produces more redness and burning and less tingling than that substance. He has employed it in *neuralgia, rheumatism* and *paralysis.* It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkaloid to an ounce of the vehicle, and the friction should be continued till a pungent sensation is produced. Turnbull probably had an impure alkaloid; the doses just mentioned would not be safe with a pure delphinine.

Staphisagrine is said to act like delphinine, except that it does not depress the heart so much

or produce fibrillary contractions. Although cases of human poisonings have occurred with staphisagria, we know of none in which the result has been fatal. The symptoms are similar to those produced in the lower animals. Kobert states that the alkaloids of staphisagria all resemble aconitine in their action, but that delphinoidine has some narcotic action.

Off. Prep.—Fluidextractum Staphisagriæ, *U. S.;* Unguentum Staphisagriæ, *Br.*

STILLINGIA. U. S.

STILLINGIA Stilling. [Queen's Root]

(stĭl-lĭn'gĭ-ą)

"The dried roots of *Stillingia sylvatica* Linné (Fam. *Euphorbiaceæ*). Preserve Stillingia in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.*

Silver Leaf, Queen's Delight, Yaw Root; Stillingie, *Fr., G.*

Stillingia sylvatica is an indigenous perennial plant, commonly called *Queen's delight,* with herbaceous stems, two or three feet high, and alternate, sessile, oblong or lanceolate-oblong, obtuse serrulate leaves, tapering at the base, and accompanied with stipules. The staminate and pistillate flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The staminate florets are scarcely longer than the bracteal scales. The plant grows in pine barrens from Maryland to Florida and west to Kansas and Texas, flowering in May and June. When wounded it emits a milky juice.

Properties.—The root, which is the part used, is large, thick, and woody. It is officially described as "entire, terete, unequally tapering, rarely branched, usually in pieces attaining a length of 40 cm. and from 0.5 to 3 cm. in diameter, externally reddish-brown, longitudinally wrinkled; fracture very fibrous; internally the bark is light reddish-brown, thick, spongy, finely fibrous, with numerous resin cells and easily separable from the porous, radiate wood; odor distinct; taste bitter, acrid and pungent. The powder is pinkish-brown or light reddish-brown; when examined under the microscope it exhibits numerous starch grains from 0.005 to 0.035 mm. in diameter, mostly single, very variable in shape, and usually with a central cleft; numerous fragments, with more or less tabular secretion cells, containing a reddish-brown, amorphous, resinous substance; fragments of tracheæ mostly with simple pores and associated with wood-fibers, the walls being very thin, lignified and possessing numerous, transverse, slit-like simple pores; bast-fibers long, narrow, the walls thick and slightly lignified; fragments of reddish-brown cork cells; occasionally crystals of calcium oxalate in rosette aggregates about 0.035 mm. in diameter. Stillingia yields not more than 5 per cent. of ash." *U. S.*

The odor is slight, peculiar, and somewhat oleaginous, but in the recent root is said to be strong and acrimonious. The taste is bitterish and pungent, leaving an impression of disagreeable acrimony in the mouth and fauces. Holm gives an excellent illustrated article on the pharmacognosy of stillingia in *Merck's Rep.,* xx, p. 412. W. Saunders has obtained from the root a volatile oil, which he found to possess the odor, taste, and peculiar acrimony of the root in a high degree. He procured six and a quarter ounces from five pounds of the dried root. It had a thick consistence, and required the addition of alcohol to render it fit for manipulation. Wm. Bichy (*A. J. P.,* 1885, p. 529) found an alkaloid which he named *stillingine.* It was obtained as an amorphous powder, volatilizable on heating, forming a sulphate in fine scale-like crystals.

Uses.—In large doses stillingia is emetic and cathartic, but is rarely used for these purposes. Smaller quantities have been supposed to exercise an alterative effect upon the system and are used in *syphilitic* and *scrofulous* conditions. The drug is probably, however, without any real value.

Dose, half a drachm to a drachm (2.0–3.9 Gm.).

Off. Prep.—Fluidextractum Stillingiæ, *U. S.;* Elixir Corydalis Compositum (from Fluidextract), *N. F.;* Fluidextractum Stillingiæ Compositum, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

STRAMONIUM. U. S. (Br.)

STRAMONIUM Stramon. [Jamestown Weed, Jimson Weed]

(strą-mō'nĭ-ŭm)

"The dried leaves of *Datura Stramonium* Linné, or of *Datura Tatula* Linné (Fam. *Solanaceæ*), without the presence or admixture of more than 10 per cent. of stems or other foreign matter, and yielding not less than 0.25 per cent. of the total alkaloids of Stramonium." *U. S.* "Stramonium Leaves are the dried leaves of Datura Stramonium, *Linn.*" *Br.*

Stramonii Folia, *Br., U. S.* 1890—Stramonium Leaves; Herba Stramonii; Thornapple Leaves; Thorn, Devil's or Mad Apple, Apple of Peru, Stink-weed, Jamestown (Jimson) Lily, Devil's Trumpet, Derotry; Stramoine ou Pomme-épineuse, *Fr. Cod.;* Feuilles de Stramoine, *Fr.;* Folia Stramonii, *P. G.;* Stechapfelblätter, *G.;* Stramonio, *It.;* Estramonio (Hoja de), *Sp.*

The *thornapple* (*Datura Stramonium*) is an annual plant, of rank and vigorous growth, usually about three feet high, but in a rich soil attains a height of six feet or more. The root is large, whitish, and furnished with numerous rootlets. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves are petiolate, five or six inches long, of an ovate-triangular form, irregularly sinuated and toothed at the edges, unequal at the base, dark green on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled, having a tubular, pentangular, five-

toothed calyx, and a funnel-shaped corolla with a long tube, and a wavy plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflexed and remains attached to the fruit. This is a large, fleshy, roundish-ovate, four-valved, four-locular capsule, thickly covered with sharp spines, and containing numerous seeds, attached to a longitudinal placenta in the center of each locule. It opens at the summit. There are two varieties of this species of Datura, one with a green stem and white flowers, the other with a dark reddish stem minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter is now considered as a distinct species, being the *D. Tatula* of Linnæus. The properties of both are the same.

It is doubtful to what country this plant originally belonged. Many European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or Asia, and it is probable that its native country is to be found in some part of the East. It is said to grow wild, abundantly in Southern Russia, from the borders of the Black Sea eastward to Siberia. Its seeds, being retentive of life, are taken in the earth put on shipboard for ballast from one country to another, not infrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connection. In the United States it is found everywhere in the vicinity of cultivation frequenting dung heaps, the road sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odor which it diffuses to some distance around. Notwithstanding the abundance of the plant, it is being cultivated in order to obtain a drug which shall be of uniform quality. The Bureau of Plant Industry, U. S. Department of Agriculture, has conducted experiments on a large scale. Several hundred pounds of leaf were grown, cured by artificial heat in a tobacco barn, and marketed at a price in advance of the highest quoted figure. Mitlacher has reported his observations on the cultivation of stramonium in *Zeit. Oest. Apoth.*, 1, p. 391. Miller has conducted comparative experiments on *D. Stramonium* and *D. Tatula.* (*A. J. P.*, lxxiv, p. 446.)

All parts of it are medicinal. The leaves, seeds, and root were formerly recognized by the U. S. P., the leaves and seed in the U. S. P., 1890, but in the U. S. P. VIII and IX the seeds were not included and the leaves alone are official under the title *Stramonium.* The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In this country the plant is generally known by the name of *Jamestown* (*vulgo, Jimson*) *weed*, derived probably from its having been first observed in the neighborhood of that old settlement in Virginia. In India *Datura alba, D. ferox,* and *D. fatuosa* are employed as poisons. The last has been admitted to the Br. (See *Daturæ Folia.*) Under the names of *Man t'o lo fa, Wan t'o lo hua,* and *Nau yeung fa,* the Chinese use as a medicine the flowers of the *Datura alba;* according to Frank Browne, they contain 0.485 per cent. of hyoscine, free from other alkaloids. *El Bethene,* a Datura of the Sahara Desert, is capable of causing delirium, coma, and death, and it is probable that all the species of the genus are poisonous. A. R. L. Dohme (*Proc. A. Ph. A.*, 1894, 231) examined stramonium to determine the value in alkaloid of the various parts of the plant; he found that, in general, the fresh parts yielded more than the dried parts; the stems contained the most alkaloid, the seeds next, then the leaves, and the roots the least of all.

The *fresh leaves* when gruised emit a fetid narcotic odor, which they lose upon drying. Their taste is bitter and nauseous. These properties, together with their medicinal virtues, are imparted to water and alcohol. Water distilled from them, though possessed of their odor in a slight degree, is destitute of their active properties. They contain, according to Promnitz, 0.58 per cent. of gum, 0.6 of extractive, 0.64 of green starch, 0.15 of albumen, 0.12 of resin, 0.23 of saline matters, 5.15 of lignin, and 91.25 of water. The leaves, if carefully dried, retain their bitter taste. They are officially described as "usually much wrinkled and either loose or more or less matted together; laminæ when entire from 2 to 30 cm. in length, having petioles from 0.5 to 8 cm. in length; inequilaterally ovate, summits acute or acuminate, bases unequal, one side extending from 3 to 12 mm. below the other, margins sinuate, toothed or angled, the teeth being few, acute or acuminate and with rounded sinuses; frequently with numerous circular perforations which may have become filled with cork; upper surfaces dark green, sparsely hairy, especially upon the veins, lower surfaces light green; odor distinct, heavy and narcotic; taste unpleasant, nauseous. Stems cylindrical, usually flattened, attaining a length of 30 cm. and a diameter of 7 mm.; longitudinally wrinkled, occasionally with 1 or more deep furrows, light greenish-brown to purplish-brown. The powder is brownish-green; upon clearing the fragments with hydrated chloral T.S. and examining under the microscope, it shows numerous elliptical stomata, about 0.025 mm. in length, and surrounded usually with 3 neighboring cells; cells of the mesophyll containing numerous small chloroplastids; calcium oxalate either in rosette aggregates, from 0.01 to 0.02 mm. in diameter, or in rod-like crystals, or in the form of sphenoidal micro-crystals; non-glandular hairs few, characteristic, 2- to 4-celled, attaining a length of 0.5 mm., the basal cell about 0.04 mm. in width, some of the cells more or less collapsed, the outer walls with numerous, slight, centrifugal projections; glandular hairs few, with 1- to 2-celled stalks and usually 2- to 4-celled,

glandular heads; tracheæ annular or spiral, fragments of the tracheal wall frequently detached. Stem fragments show large annular or spiral tracheæ which occasionally are thickened, with simple or bordered pores and associated with wood parenchyma; fragments with long, narrow unequally thickened collenchymatous cells; parenchyma with sphenoidal micro-crystals; wood-fibers occasional; bast-fibers absent. Stramonium yields not more than 20 per cent. of ash." *U. S.*

J. S. Ward has found commercial stramonium leaves freely adulterated with those of *Carthamus helenioides* and *Xanthium Strumarium.* (*P. J.*, lxvi, 326.) For a paper on the structure of the leaves of *D. Stramonium, Atropa Belladonna,* and *Hyoscyamus niger* by Schlotterbeck and van Zwaluwenburg, see *Proc. A. Ph. A.*, 1897, 202. Holm has published an illustrated article on the morphology of stramonium. (*M. R.*, xxii, p. 162.) Rosenthaler has subjected the leaves of stramonium to pyro-analysis and obtained a distinctive and characteristic sublimate. (*B. P. G.*, xxi, p. 530.)

The following are some of the more common synonyms used to designate stramonium seeds: *Stramonii Semina, Stramonium Seed, Semen Stramonii,* P. G.; *Semences* (*Graines*) *de Stramoine,* Fr.; *Stechapfelsamen,* G., which were formerly official. The *seeds* are small, kidney-shaped, pitted and wrinkled, flattened on the sides, of a dark-brown almost black color, inodorous unless bruised, and of the bitter, nauseous taste of the leaves, with some degree of acrimony. The testa is dull brownish-black, hard, and encloses a cylindrical curved embryo, which is embedded in a whitish oily albumen. They are much more energetic in their action on the system than are the leaves. Hirtz and Hopp inferred from their experiments that one part of an extract prepared from them was equal in strength to five parts of an extract prepared in precisely the same manner from the leaves. (*Ann. Thér.*, 1862, p. 22.)

Geiger and Hesse succeeded in isolating an alkaloid, to which the name *daturine* was given, and which Trommsdorff has repeatedly procured by their process. Von Planta (*A. J. P.*, 23, p. 38) found that daturine was identical with atropine, and this result has since been confirmed; but Ladenburg (*Ber. d. Chem. Ges.*, 13, p. 909) found that *Datura Stramonium* contains two alkaloids, which he designated as *heavy daturine* and *light daturine.*

The more difficultly soluble heavy daturine fuses at 113.5° to 114° C. (236.3°–237.2° F.), and must be considered as a mixture of *atropine* and *hyoscyamine.* It yields a gold salt fusing between 135° and 150° C. (275° and 302° F.), out of which, by crystallization repeated six times and by rejection each time of the mother liquor, is obtained hyoscyamine gold-chloride fusing at 158° to 160° C. (316.4°–320° F.). From the mother liquors by evaporation is obtained nearly pure atropine gold chloride fusing at 135° to 140° C. (275°–284° F.). If the heavy daturine be repeatedly crystallized out of dilute alcohol, pure atropine can be isolated from it, fusing at 113.5° to 114.5° C. (236.3°–238.1° F.), and yielding a lusterless gold salt fusing at 135° to 139° C. (275°–282.2° F.). The light daturine is the alkaloid which Ladenburg and Meyer in a previous study had shown to be identical with hyoscyamine. Hence *Datura Stramonium* contains the two alkaloids *atropine,* $C_{17}H_{23}O_3N$, and *hyoscyamine,* isomeric with the other, which *Atropa Belladonna* also contains. (*A. J. P.*, 1884, 440.) The mother liquors from which hyoscyamine is obtained yield a difficultly crystallizable base, first called hyoscine, but now known as *scopolamine.* Its gold salt is more difficultly soluble than the gold salts of atropine and hyoscyamine, and affords a means of separation. The base, when purified, can be crystallized out of ether in colorless crystals, melting at 59° C. (138.2° F.). Its formula is $C_{17}H_{21}O_4N$, and it is decomposed by boiling with baryta water into *scopolin,* $C_8H_{13}NO_2$, and *atropic acid,* $C_9H_8O_2$. (Schmidt, *Pharm. Chemie,* 3te Auf., ii, 1339.)

Gérard (see *J. P. C.*, 1892, 8) studied *daturic acid* obtained from stramonium seed. D. Holde has, by means of benzene, extracted from stramonium seed 16.7 per cent. of a fixed oil. (*P. J.*, lxx, p. 90.) This has been examined by J. M. Baird and F. E. Sleeper, see *Proc. A. Ph. A.*, 1903, 324.

Assay of Stramonium.—"Proceed as directed under *Belladonnæ Radix,* page 222, using 15 Gm. of Stramonium, in No. 60 powder, increasing the amount of water to be added after maceration to 25 mils, and, before titration, treating the final residue twice with 5 mils of ether, evaporating to dryness each time.

"Each mil of tenth-normal sulphuric acid consumed corresponds to 28.92 milligrammes of the total alkaloids of Stramonium." *U. S.*

"Ovate, petiolate, usually from ten to fifteen centimetres long, often unequal at the base; margin sinuate-dentate, apex acuminate. Upper surface dark greyish-green; under surface paler, and minutely wrinkled. Walls of the epidermal cells sinuous; stomata on both surfaces; on the lower surface, especially of young leaves, curved multicellular hairs with thin, warty walls, and also glandular hairs with unicellular or multicellular stalks; in the mesophyll numerous cluster-crystals of calcium oxalate. Characteristic odor; taste bitter, unpleasant. Ash not more than 18 per cent." *Br.*

Uses.—Stramonium is so similar to belladonna in the symptoms produced by it in small or large doses, in its toxicity and its general physiological and therapeutic action, that the two drugs are practically identical. Furthermore, they are about the same strength in activity, so the preparations may be used in similar doses. Stramonium has been employed in all the conditions for which belladonna is more commonly used, but has acquired special repute in the treatment of *asthma,* this probably being due to the fact that the practice of smoking *Datura ferox* in that disease was introduced into Great Britain from the East Indies by

General Gent, and that afterwards the English species was substituted for that employed in Hindostan. Formerly the roots were chiefly used, but at present the dried leaves are exclusively employed. The beneficial effect is doubtless due to the presence of atropine which paralyzes the endings of the pulmonary branch of the vagus, thus relieving the bronchial spasm, for Gunther (*W. K. W.*, 1911, p. 748) has shown that the smoke from a stramonium cigarette containing 1.25 Gm. of stramonium leaves contains as much as 0.5 Mgm. of atropine. The leaves may be made up into cigarettes or smoked in a pipe, either with or without a mixture of tobacco; more commonly, however, the coarsely ground leaves are mixed with equal parts of potassium nitrate, in order to increase combustion, and burned in a saucer.

Death is said to have been produced by the free use of the India *Datura ferox*, but it seems hardly possible that the species which is found in North America would produce such a result.

The seeds are more powerful than the leaves. The seeds were once officially recognized, but the presence of a large amount of fixed oil made it difficult to extract them or to make stable preparations from them and the leaves have taken their place. They may be given in the dose of one-half to one grain (0.032–0.065 Gm.) twice a day; an extract made by evaporating the decoction, in one-quarter or one-half the quantity. The inspissated juice of the fresh leaves was formerly very commonly prescribed; but the alcoholic extract is now almost exclusively used, the dose being half a grain (0.032 Gm.). (See *Extractum Stramonii.*)

Dose, of the leaves, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Extractum Stramonii (Pilular and Powdered), *U.S.;* Tinctura Stramonii, *U. S., Br.;* Unguentum Stramonii (from Pilular Extract), *U. S.;* Fluidextractum Stramonii, *N. F.*

STRONTII BROMIDUM. U. S., Br.

STRONTIUM BROMIDE Stront. Brom.

(strŏn'tĭ-ī brō'mĭ-dŭm)

"It contains not less than 98 per cent. of $SrBr_2 + 6H_2O$ (355.57). Preserve it in well-closed containers." *U. S.* "Strontium Bromide may be obtained by neutralising dilute hydrobromic acid with strontium carbonate, evaporating and crystallising. It contains not less than 97 per cent. of pure strontium bromide, $SrBr_2,6H_2O$." *Br.*

Bromure de Strontium, *Fr. Cod.;* Strontiumbromid, *G.;* Bromuro Estroncico, *Sp.*

This salt, made official in the U. S. P., 1890, may be made by burning strontium in bromine vapor, by dissolving strontium carbonate in hydrobromic acid, or by substituting hydrobromic acid for hydrochloric acid in the latter part of the process given for preparing strontium salts. (See page 1066.)

Properties.—"Strontium Bromide occurs as colorless, transparent, hexagonal crystals; odorless, and having a bitter, saline taste. The salt deliquesces in moist air but effloresces in very dry air. One Gm. of Strontium Bromide dissolves in 0.35 mil of water at 25° C. (77° F.); soluble in alcohol; insoluble in ether. Its aqueous solution (1 in 20) is neutral to litmus. When quickly heated, the crystals at first melt, and at above 180° C. (356° F.) lose all of their water of crystallization. To a non-luminous flame the salt communicates a crimson color. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 10) produces a yellowish-white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water. With calcium sulphate T.S. an aqueous solution of the salt (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids; the precipitation occurs more quickly with diluted sulphuric acid or a readily soluble sulphate. Add a few drops of ferric chloride T.S. and 1 mil of chloroform to 10 mils of an aqueous solution of the salt (1 in 20) and shake the mixture; the chloroform does not acquire a violet tint (*iodine*). Drop 1 mil of diluted sulphuric acid upon about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). Dissolve 1 Gm. of Strontium Bromide and 1 Gm. of sodium acetate in 5 mils of distilled water, and render the solution slightly acid by the addition of from 3 to 5 drops (or a sufficient quantity) of diluted acetic acid. The solution, upon the addition of 5 drops of potassium dichromate T.S. and agitation, does not become cloudy within three minutes (*barium*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Proceed as directed under the Assay for bromides (see Part III, Test No. 5), using about 0.8 Gm. of Strontium Bromide, accurately weighed. It shows not less than 98 per cent. of $SrBr_2 + 6H_2O$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.017778 Gm. of $SrBr_2 + 6H_2O$. Each gramme of Strontium Bromide corresponds to not less than 55.1 mils nor more than 56.6 mils of tenth-normal silver nitrate V.S." *U. S.*

"White acicular crystals, deliquescent. Taste saline, slightly bitter. Soluble in less than 1 part of *water*, and in *alcohol* (90 per cent.). Yields the *reactions* characteristic of bromides; an aqueous solution slowly deposits a crystalline precipitate on the addition of *solution of calcium sulphate*. A solution of 1 gramme in *water*, to which 5 millilitres of *solution of sodium acetate* and 3 millilitres of *acetic acid* have been added, does not become cloudy on the addition of 1 millilitre of *solution of potassium chromate* (absence of barium). 1 gramme dissolved in *water* requires for complete precipitation not less than 54.6 or more than 57 millilitres of *N/10 solution of silver nitrate*. 0.5 gramme moistened with *sulphuric acid* and gently ignited leaves a white residue weighing not less than 0.250 gramme. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million." *Br.*

For further tests, see *Proc. A. Ph. A.*, 1897, 608.

Uses.—Strontium bromide has been strongly commended as a substitute for potassium bromide in the treatment of *epilepsy* and allied conditions. It depends for its action on the nervous system upon the presence of bromine in it, and appears to act upon the nervous centers in much the same manner as does the corresponding salt of potassium. Its influence upon the general nutrition is much more favorable than is that of the potassium salt, and it is much less apt to produce the disagreeable effects of bromism. Moreover, it is less irritating to the gastro-intestinal mucous membranes, on which, indeed, it often seems to exert a beneficial influence. For these reasons many cases of epilepsy tolerate it much better than they do other bromides. In the experience of H. C. Wood, however, it seemed to be in its anticonvulsive influence among the least powerful and certain of its class. Possibly this result has been due to Wood not having employed it in sufficient dose, he never having administered more than two drachms a day, while the French observers affirm that it may be given with great advantage in the daily dose of three drachms. Strontium bromide is further stated by Sée to have an extraordinary influence in the reduction of the excretion of sugar in *diabetes*, and to be a valuable remedy in the treatment of *gastric dilatation* and *catarrh*.

Dose, fifteen to thirty grains (1–2 Gm.).

STRONTII IODIDUM. U. S.

STRONTIUM IODIDE Stront. Iod.

(strŏn'tĭ-ī ī-ŏd'ĭ-dŭm)

"It contains not less than 99 per cent. of $SrI_2 + 6H_2O$ (449.57). Preserve it in small, amber-colored, glass-stoppered bottles, carefully protected from light." *U. S.*

Iodure de Strontium, *Fr.*; Strontiumjodid, *G.*

This official salt may be made by evaporating a solution of hydriodic acid saturated with strontium hydroxide or carbonate.

Properties.—"Strontium Iodide occurs as colorless, transparent, hexagonal plates, as a white, granular powder, or in crystalline crusts; odorless, and having a bitter, saline taste. It is deliquescent, and is colored yellow by exposure to air and light. One Gm. of Strontium Iodide dissolves in about 0.2 mil of water at 25° C. (77° F.); soluble in alcohol; slightly soluble in ether. Its aqueous solution (1 in 20) is neutral or slightly alkaline to litmus. When cautiously heated, the crystals melt and gradually lose their water of crystallization. At a red heat, the salt is decomposed, losing iodine and leaving a residue of strontium oxide. To a non-luminous flame it imparts a crimson color. When calcium sulphate T.S. is added to an aqueous solution (1 in 10) it slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids; the precipitation occurs more quickly with diluted sulphuric acid or a readily soluble sulphate. Add 1 mil of ferric chloride T.S. to 5 mils of an aqueous solution of the salt (1 in 20); iodine is liberated, which imparts a violet color to chloroform, when shaken with it. Dissolve 1 Gm. of Strontium Iodide and 1 Gm. of sodium acetate in 5 mils of distilled water, and render the solution slightly acid by the addition of from 3 to 5 drops (or a sufficient quantity) of diluted acetic acid. The solution, upon the addition of five drops of potassium dichromate T.S. and agitation, does not become cloudy within three minutes (*barium*). Gently heat 5 mils of an aqueous solution of the salt (1 in 10) with 1 drop of ferrous sulphate T.S., 1 drop of ferric chloride T.S., and 0.5 mil of potassium hydroxide T.S.; no blue color appears after acidulating the mixture with hydrochloric acid (*cyanide*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Dissolve 0.3 Gm. of the salt in 5 mils of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid; filter, digest the precipitate with 5 mils of ammonia water and filter. On saturating the filtrate with nitric acid, not more than a slight turbidity is produced (*chloride or bromide*).

"**Assay.**—Proceed as directed under the Assay for iodides (see Part III, Test No. 5), using about 1 Gm. of Strontium Iodide, accurately weighed. It shows not less than 99 per cent. of $SrI_2 + 6H_2O$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.022478 Gm. of $SrI_2 + 6H_2O$. Each gramme of Strontium Iodide corresponds to not less than 44 mils of tenth-normal silver nitrate V.S." *U. S.*

Uses.—This salt has been brought forward as a means of obtaining the alterative influence of an iodide without irritating the intestinal tract or depressing the general nutrition. It contains about 56.5 per cent. of iodine, and, although its actual value has scarcely as yet been made out, may be substituted for potassium iodide in various diseases.

Dose, five to fifteen grains (0.32–1.0 Gm.).

STRONTII SALICYLAS. U. S.

STRONTIUM SALICYLATE Stront. Salicyl.

(strŏn'tĭ-ī săl-ĭ-cȳ'lăs)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of $Sr(C_7H_5O_3)_2 + 2H_2O$ (397.74). Preserve it in well-closed containers, protected from heat and light." *U. S.*

Strontium Salicylicum; Salicylate de Strontium, *Fr.*; Salicylsaures Strontium, Strontiumsalicylat, *G.*

Preparation.—This salt is made by adding 10 parts of salicylic acid to 100 parts of hot water and then adding 5.3 parts of pure strontium carbonate, filtering, evaporating and crystallizing.

Properties.—It is officially described as "a white, crystalline powder; odorless, and having a somewhat sweet, saline taste. One Gm. of

Strontium Salicylate dissolves in 19 mils of water, and in 61 mils of alcohol at 25° C. (77° F.); also in 3.7 mils of boiling water and in 14 mils of boiling alcohol. When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a residue of strontium carbonate and carbon. To a non-luminous flame it imparts a crimson color. An aqueous solution of the salt (1 in 30) is colorless. With calcium sulphate T.S. an aqueous solution of the salt (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids. Add a few drops of ferric chloride T.S. to an excess of a concentrated aqueous solution of Strontium Salicylate; a dark red color and a precipitate are produced; in an aqueous solution of the salt (1 in 100) a deep violet-blue color is produced. Diluted hydrochloric acid produces a voluminous, white precipitate of salicylic acid in a concentrated aqueous solution of the salt. Add 1 mil of diluted sulphuric acid to 10 mils of an aqueous solution of Strontium Salicylate (1 in 50) and filter; the filtrate does not respond to the Test for heavy metals (see Part III, Test No. 3). Agitate 2 Gm. of Strontium Salicylate with 10 mils of diluted acetic acid, heat the mixture, cool, and then filter. The filtrate, upon the addition of 5 drops of potassium dichromate T.S., does not become cloudy within three minutes (*barium*).

"**Assay.**—Introduce into a platinum crucible about 2 Gm. of Strontium Salicylate, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, and thoroughly carbonize it at a temperature not exceeding red heat. Dissolve the residue in 30 mils of half-normal hydrochloric acid V.S., and submit it to residual titration with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows, in the dried salt, not less than 99 per cent. of $Sr(C_7H_5O_3)_2 + 2H_2O$.

"Each mil of half-normal hydrochloric acid V.S. used corresponds to 0.099435 Gm. of $Sr(C_7H_5O_3)_2 + 2H_2O$. Each gramme of Strontium Salicylate, previously dried, corresponds to not less than 9.96 mils of half-normal hydrochloric acid V.S." *U. S.*

Uses.—Strontium salicylate when taken internally is slowly decomposed in the alimentary canal with the liberation of salicylic acid, which acid or its educts can be detected in the urine shortly after administration. As a salicylate, the strontium salt is of especial value in subacute *rheumatic* affections, acting more slowly and persistently than most of the other allied salts, and having much less tendency to disturb the digestion. Blankenhorn (*J. A. M. A.*, 1916, lvi, p. 331) from comparative studies in twenty-three cases of various diseases, has come to the conclusion that the toxic dose of strontium is the same as that of sodium salicylate, and that the strontium salt has no advantage in any way. It may be administered in capsule or in solution.

Dose, five to thirty grains (0.32–2.0 Gm.).

STRONTIUM

STRONTIUM

(strŏn'tĭ-ŭm)

$Sr = 87.63$

Strontium belongs to the alkaline earth-group of metals along with barium and calcium. It is a yellow metal, of the sp. gr. 2.5, somewhat harder than lead, and is sufficiently malleable to be hammered out into thin plates. It oxidizes quickly on exposure to air, and hence must be kept under naphtha, like the alkali metals. It has so far been prepared only in a small way by electrolysis from the chloride or the hydroxide, the best procedure being that of Bunsen and Matthiessen.

For the preparation of pure salts, Barthe and Falières found that the following method permits the preparation of pure strontium salts with comparative ease, and has the advantages that no heat is necessary, and that the chemicals employed need not be pure.

Dissolve natural strontium carbonate (or the sulphide obtained by reduction of the sulphate) in just sufficient diluted hydrochloric acid (1 to 5); it will be an advantage if some of the carbonate or sulphide remains undissolved. The clear liquid, which contains calcium, barium, and strontium salts, besides small quantities of iron, aluminum, and magnesium, is decanted from the deposit, and a small excess of ammonia added, which precipitates iron and alumina. To the filtrate is added an excess of sulphuric acid; the precipitate consisting of strontium, barium, and calcium sulphates, is washed repeatedly by decantation with water containing from 1 to 2 per cent. of sulphuric acid, and finally with distilled water. This will remove all traces of magnesium and calcium sulphate. The precipitate is next treated in the cold with an excess of a solution of ammonium or potassium carbonate (1 to 10), stirring frequently for two days, and finally washing with distilled water by decantation. The mixture of carbonate and sulphate is treated with diluted hydrochloric acid, which dissolves strontium carbonate and traces of baryta. After allowing it to stand for twenty-four hours the clear liquid is decanted and filtered through a filter previously washed with diluted hydrochloric acid. To the perfectly clear filtrate are added 200 Gm. of hydrochloric acid per liter, and then from 2 to 3 Gm. of precipitated strontium sulphate, which may contain barium sulphate; stirring frequently for several hours. The strongly acid liquid dissolves a little strontium sulphate (about 0.25 per cent.), but in proportion as the strontium is dissolved the barium takes hold of the sulphuric acid, while an equivalent quantity of strontium chloride is formed. The strontium sulphate being in excess will insure the final elimination of all the barium. The filtrate is evaporated to dryness, the salt dissolved in three times its weight of distilled water, allowed to stand for twenty-four hours, filtered, evaporated to crystallization, and dried. The crystals showed in

the spectroscope only the lines of strontium. (*Bull. Soc. Chim.*, 1892, 104.)

Strontium nitrate is largely used for making *red fire* in pyrotechnics; the salt is made by dissolving strontium carbonate in diluted nitric acid, evaporating the solution and crystallizing.

Uses.—At one time the strontium salts were deemed to be highly toxic, but in 1890 Laborde (*C. R. S. B.*, 1890, ii) showed that this belief was due to the fact that the earth had been contaminated with barium salts and that pure strontium was no more injurious than potassium. When a salt of strontium is taken by the mouth probably only small amounts of the metal are absorbed. The fact that it is excreted chiefly by the intestinal glands (Mendel and Thatcher, *A. J. Phys.*, 1904, xi, 5) makes it difficult to determine whether the salt found in the feces has been absorbed and re-excreted, or whether it is simply due to non-absorption. Even after hypodermic administration only traces of the metal appear in the urine. Wood and Arnold (*Phila. Monthly Medical Journal*, April, 1899) have shown that when introduced into the blood stream the strontium salts exercise a marked stimulating effect upon both the heart and arterial muscles, which are secondarily depressed by toxic doses. It causes also an increase in the contractions of the voluntary muscles with delay in their relaxation. Taken by the mouth, however, it is so slowly absorbed that it is improbable that enough can be introduced into the system to exercise any influence. According to Mendel and Thatcher, small quantities are stored up in the bones replacing a part of the calcium.

The salts of strontium, especially *strontium lactate*, were at one time extensively employed in the treatment of *chronic Bright's disease*. The remarkable claim was made for them that not only did they have a valuable diuretic effect, but that they exercised a beneficial effect upon the kidney, causing marked diminution in the excretion of albumin. Later experience, however, has not justified the earlier enthusiasm, and the use of the metal, except as a carrier of therapeutically active acids, has almost dropped out of vogue. By some it is believed that the strontium salts are less liable to disturb digestion. Especially has this been urged in regard to the salicylate, but in the experiments of Blankenhorn (*J. A. M. A.*, 1916, lvi, 331), there was no difference in the effects of the strontium and sodium salicylate.

STROPHANTHINUM. U. S.

STROPHANTHIN Strophanthin.

(strō-phan-thĭ'nŭm)

"A glucoside or mixture of glucosides obtained from *Strophanthus Kombe* Oliver (Fam. *Apocynaceæ*). Preserve it in well-closed containers, protected from light." *U. S.*

Strophantine, *Fr. Cod.*; Strophanthin, *G.*

Preparation.—*Strophanthin* may be prepared by Fraser's process of depriving the ground seeds of fatty oil by percolation with petroleum benzin, making a tincture from the marc with 70 per cent. alcohol, distilling, evaporating and treating the extract with water; this solution is then filtered and the filtrate precipitated with tannic acid; the precipitate is washed, mixed with litharge, dried and exhausted with alcohol; by adding ether to the alcoholic liquid, strophanthin is precipitated. For an improved method, see Rowe, *J. A. Ph. A.*, 1916, v, 1183.

Properties.—It is officially described as "a white or yellowish powder containing varying amounts of water, which it does not lose entirely without decomposition. It is permanent in the air. *Great caution must be used in tasting it and then only in very dilute solutions.* Strophanthin is very soluble in water and in diluted alcohol, less soluble in dehydrated alcohol; nearly insoluble in chloroform, ether, or benzene. Its solutions are neutral to litmus and are dextrorotatory. Sulphuric acid added to Strophanthin produces an emerald-green color, changing to brown. Add a trace of ferric chloride T.S. and a few mils of sulphuric acid to an aqueous solution of Strophanthin; a red-brown precipitate is produced which turns dark green after one or two hours. No weighable ash remains on incinerating 0.1 Gm. of Strophanthin. A solution of 0.1 Gm. of Strophanthin in 15 mils of distilled water, when mixed with 5 mils of hot alkaline cupric tartrate V.S., produces no precipitate; but on heating an aqueous solution to 70° C. (158° F.), with a small amount of dilute hydrochloric acid (1 in 20) it is hydrolized into strophanthidin, which precipitates, and a sugar which remains in solution. The latter is capable of reducing alkaline cupric tartrate V.S." *U. S.*

For further details of the various kinds of strophanthin and their properties, see *Strophanthus* and *Acocanthera* (Part II).

Uses.—Strophanthin fully represents the therapeutic properties of strophanthus. While occasionally used by the mouth it is usually reserved where it is desirable to administer the drug by injection. On account of its intense local irritant effect the hypodermic injection is not to be recommended, the drug may, however, be thrown into the muscle substance or better, directly into a vein. In cases of severe *circulatory failure*, such as that seen in *pneumonia* and other infectious diseases, in *collapse* from *ether anesthesia*, and in *uremia*, striking results are often obtained by the intravenous injection of strophanthin. Bailey (*J. P. Ex. T.*, 1909, i, p. 349) finds the treatment of the utmost value as an emergency measure in broken compensation of *heart disease*, but not suitable for continuous use.

The confusion concerning the identity of the various strophanthins, as well as the extraordinary difference in their activity according to the channel of administration, has given rise to great diversity of statement as to the proper dosage of these glucosides. A long summary of the literature on this subject is given in *Merck's Report* for 1912, as a result of which the conclusion is reached that when given in-

travenously G-strophanthin is nearly twice as strong as the K-strophanthin (the official), but that when exhibited by the mouth G-strophanthin is very much weaker than the official. The conclusions reached from this article are that the maximum *daily* dose of these glucosides should not exceed for G-strophanthin, intravenously, one sixty-fourth of a grain (0.001 Gm.), by mouth, one-half grain (0.032 Gm.). Of the K-strophanthin intravenously, one-fortieth grain (0.0016 Gm.), by mouth, one-twentieth of a grain (0.003 Gm.).

For a discussion of the various strophanthins, see *Strophanthus.*

Dose, one two-hundredth of a grain (0.0003 Gm.).

STROPHANTHUS. U. S. (Br.)

STROPHANTHUS Strophanth.

(strō-phăn-thŭs)

"The dried, ripe seeds of *Strophanthus Kombe* Oliver, or of *Strophanthus hispidus* De Candolle (Fam. *Apocynaceæ*), deprived of the long awns. If made into the official tincture and assayed biologically the minimum lethal dose should not be greater than 0.00006 mil of tincture, or the equivalent in tincture of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog. Preserve Strophanthus in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.* "Strophanthus Seeds are the dried ripe seeds of Strophanthus Kombé, *Oliver,* freed from the awns." *Br.*

Strophanthi Semina, *Br.;* Strophanthus Seeds; Strophantus, *Fr. Cod.;* Semen Strophanti, *P. G.;* Strophanthussamen, *G.;* Strofanto, *It.;* Estrofanto (Semilla de), *Sp.*

Strophanthus continues to have considerable interest among pharmacognosists and pharmacologists. There is no fixed principle of agreement in the several pharmacopœias. Meyer (*A. Pharm.,* 1908, p. 51) very correctly states that it is for the pharmacologist and therapeutist to determine the relative values of each of the seeds before it is possible to determine whether one specis may be substituted for another. In Germany the needs of *Strophanthus hispidus* are preferred because of their guaranteed purity. (*Ber. d. D. Pharm. Ges.,* xviii, p. 284.) On the other hand, the British Pharmacopœia, the French Codex and the Swiss Pharmacopœia confine their official definitions to *S. Kombe.* The U. S. Pharmacopœia alone recognizes both species, the *S. hispidus* being added because of the arguments that have been advanced in this country as to the efficacy of these seeds. The literature in recent years on the question of strophanthus has been quite voluminous. Some of the more interesting articles being the following: Thoms (*Arb. a. d. Pharm. Inst. d. Univ. Berlin,* 1905, p. 74); Gilg (*Ibid.,* p. 59); Pabisch (*Zeit. Oest. Apoth. Ver.,* xlvii, p. 509); Gilg (*B. P. G.,* xviii, p. 284); Hartwich (*Ap. Ztg.,* xxvi, p. 94).

According to Engler and Prantl, there are twenty-eight recognized species of the genus found in Africa and Asia, extending to China, the East Indies, and the Philippines. The commercial drug is often largely composed of the seeds of other than the recognized official species, and may contain the seeds from related genera, especially those of *Kickxia africana* Benth. The seeds of *Kickxia africana* are without hairs, spindle-shaped, not flattened, twisted into an S-like shape, and with the base and the summit of the seed alike in their forms. On cross-section the cotyledons are seen much folded, while those of the strophanthus lie parallel one upon the other. The transverse section of the kickxia seed, when treated with concentrated sulphuric acid, first turns brown, then red, while the seeds of both kinds of strophanthus take on a green color. According to Stapf, the plant represents a new genus and should be known as the *Funtumia africana;* the only other species of the genus, *F. elastica,* yields India rubber.

The seeds of all the species of strophanthus apparently possess hairs that have a characteristic thickened base somewhat resembling those of nux vomica seeds. The seeds of various species of the genus strophanthus are used for the preparation of arrow poison in Africa, at Kombé in the Manganja country, in the Gaboon district, and in Guinea and Senegambia. In Gaboon this poison is called *inée, onaye,* or *onage.* (See also *Acocanthera,* PART II.) The plant which yields the arrow poison of Kombé was first brought to Europe by Sir John Kirke and described as a new species by Oliver, of Kew, under the name of *S. Kombe.* There can be no doubt that much of the Strophanthus of commerce is yielded by other species. *S. Kombe* grows solely in East Africa, as far as is known, so that all of the drug coming from West Africa must be yielded by other species. The tracing of the origin of the seeds is made more difficult by the fact that in Africa seeds from different regions are mixed before shipment. The seeds of *S. hispidus* enter commerce, as do also those of *S. glaber, S. emini,* and *S. courmontii.* (*P. J.,* 1899, lxiii, p. 321.) A white woolly strophanthus is said to be yielded by *S. Nicholsoni,* a species first characterized by Holmes (*P. J.,* 1897, lix, 208). *S. gratus* of Sierre Leone also contributes its seeds; also *S. glaber* contains *ouabain,* which, according to Karsten, is identical with strophanthin. (*C. R. A. S., cxxvi,* 346.)

Sharp (*P. J.,* 1912, lxxxviii, p. 159) has found that the seeds of the *S. courmontii* are about one-fourth as poisonous to frogs as those of the *S. Kombe,* but their physiological effects are of a similar type. The seeds of the *S. emini* Asch, he found to be almost without action upon the frog's heart. The seeds of the *S. Thalloni* and of the *S. Tarmentosus* A. D. C., are also active.

S. hispidus when by itself takes the form of a bush, but usually occurs as a woody climber inhabiting the forests between the coasts and the center of the African continent. It reaches

to the tops of the highest trees, coiling on the ground, and hanging in festoons from tree to tree. The stem is several inches in diameter. The flowers are cream-colored, yellow at the base, purplish-spotted above. They are grouped in terminal cymes. The lobes of their gamopetalous corollas are prolonged into very narrow tail-like ends being nine or more inches in length. They last but a short time during the months of October and November. The fruit, a pair of follicles from 10 to 17 inches long, is ripe in June, and is gathered by the natives, who scrape off the husks (epicarp and mesocarp) before drying, and preserve the more leathery internal inner covering (endocarp) with the enclosed seeds; hence the pods as they appear in commerce are smooth and of a tawny color. The seeds themselves are covered with long comose hairs, which, being deciduous, are apt to be lost before the escape of the seed from the pod. In preparing the arrow poison, the natives are said to pound the seeds deprived of their hairs to a pulp, add the adhesive sap of another plant, and simply smear the mixture for six inches along the point of the arrow. Game wounded by such an arrow is said to be rarely able to move a hundred yards, and the flesh is eaten without bad effect. Karsten has examined the *root* of Strophanthus hispidus and found that it contained *trigonelline, choline* and *strophanthin* in such small proportions that it will probably never be commercially valuable. (*B. P. G.,* 1902; 12, 241.)

Properties.—Strophanthus occurs in commerce either in pods or as clean seeds. Helbing states (*P. J.,* March, 1887) that he has found the seeds to constitute about 37 per cent., the pod (endocarp) 37 per cent., and the hairs about 25 per cent., and says that the quality of the pods may be determined by examining the color of the pappus. If this is white and bright, the seeds and pods are in good condition.

At present strophanthus seeds are much less mixed than formerly. In 1892 Hartwich classified commercial strophanthus seeds (*A. Pharm.,* 1892, 401), in the following groups: (1) The official products yielded by *S. hispidus* or *S. Kombe,* which contain strophanthin and no crystals of calcium oxalate. (2) Those resembling the official seeds, but of different habitat—viz., Mozambique and Sierre Leone. (3) Those which contain calcium oxalate crystals, but no strophanthin—viz., Senegal, Lagos, Niger, German East Africa, Togoland, and Baol of Senegal. (4) A very hairy seed from the Upper Niger. The hairs vary in color from a silky white to brown; the embryo contains calcium oxalate crystals, but the seeds do not contain strophanthin. (5) Seeds which are said to be glabrous, but possess hairs in the region of the raphe. These include those from Lagos and Zambesi, and contain neither calcium oxalate crystals nor strophanthin. In 1896 S. E. Jelliffe stated that there are in the American market two hairy seeds, the product respectively of *S. hispidus* (Kombe) and *S. asper,* and one smooth seed, *S. gratus* of the Gaboon. (See *D. C.,* 1896, 101.) The seeds of *S. Gratus* are recommended by E. Gilg as more easily recognized than the others and because it yields strophanthin more readily in crystalline form. (*B. P. G.,* 1904, 90.) There are two chief varieties both of which are now official.

The more important of the rarer varieties of strophanthus are composed of seeds which at one time were much mixed in Africa before exportation with those of *S. Kombe* and *S. hispidus* and are the products of two species, *S. glabra* and *S. Thalloni.* The seeds of *S. glabra* are about 13 to 16 Mm. long from 3 to 4½ Mm. wide, and from 1 to 1½ Mm. thick. They are lanceolate with a rounded or truncated base and a long attenuate apex. The ventral face is flat or concave, the dorsal being convex, and possesses sometimes a small keel near the shaft. The surface is glabrous, of a dull waxy appearance; the color varies from an ochre-yellow to a fawn or cinnamon; the odor is characteristic; the fracture is horny and the taste extremely bitter. The hairs of the awn are about 7 Cm. in length, numerous, silky, white, and when viewed in a mass yellowish or grayish. The seed coat is relatively thin; the albumen is thick and cartilaginous; the embryo is not thick, the radicle is as long as in *S. hispidus* or *S. Kombe.* With concentrated sulphuric acid the color changes from yellow to rose and finally to violet. For an elaborately illustrated article on the histology of *S. Kombé,* by P. E. F. Perredes, see *W. C. R. L.,* No. 15; see also *B. P. G.,* 1904, 104, 120.

The seeds of *S. gratus* (Wall et Hook.) Franch, are characterized by their uniform and reliable activity and it has been suggested that they may replace advantageously those of *S. Kombe.* They are obtained from plants growing in the Senegal and Congo, the same region in which *S. hispidus* is found. According to Gilg the seeds are spindle-shaped, being at the basis more or less rounded, although sometimes truncate. In the upper portion, they are sharply angular, sometimes being winged and gradually tapering at the summit. Externally the seeds are of a characteristic yellow or yellowish-brown. They vary in length from 11 to 19 Mm., in breadth from 3 to 5 Mm., and in thickness from 1 to 1.3 Mm. In taste they are strongly and persistently bitter. On the addition of sulphuric acid to microscopic sections the latter are colored reddish or of a rose tint, changing to a deep red or violet.

The seeds of *S. Thalloni* are very long and narrowly spindle shaped, tapering above and below, and covered with numerous brownish hairs. A smooth blackish-brown Strophanthus seed is said to be sent into commerce from Indo-Malaya.

The seeds of *S. Courmontii* are 8 to 14 Mm. in length, 2.5 to 3.5 Mm. in breadth and 1 to 2 Mm. in thickness; of a distinctly lanceolate form and decidedly brown color, often with the hairs rubbed off, but having a golden sheen when these remain, while the tint is dull and

reddish when they are absent. The ridge on the ventral surface is indistinct and the arrangement of the hairs in longitudinal rows is not as apparent as in the official seed. They also contain crystals of calcium oxalate in abundance, which have been stated by some observers to be entirely absent from *S. Kombe* and *S. hispidus* but are in fact there in very small amount. The seeds of *S. elemi* are grayish-green in hue and contain crystals of calcium sparingly in the embryo. The statement of E. M. Holmes (*P. J.*, lxiv) that the seeds of *S. Kombe* and *S. hispidus* give with sulphuric acid a greenish reaction, while those of *S. Courmontii* give a reddish, and *S. elemi* a yellowish-brown changing into reddish, seems not to be absolutely accurate, for while the seed albumen of *S. Kombe* always gives the greenish reaction the cotyledons frequently are mottled with red and rarely give an entirely red reaction. (Perredes.)

Strophanthus is officially described as "lance-ovoid, flattened and obtusely edged; from 7 to 20 mm. in length, about 4 mm. in breadth and about 2 mm. in thickness; externally of a light fawn color with a distinct, greenish tinge, silky lustrous from a dense coating of closely appressed hairs (*S. Kombe*); or light to dark brown, nearly smooth and sparingly hairy (*S. hispidus*), bearing on one side a ridge running from about the center to the summit; fracture short and somewhat soft, the fractured surface whitish and oily; odor heavy when the seeds are crushed and moistened; taste very bitter. Under the microscope, sections of *Strophanthus Kombe* show a seed-coat composed of several layers of more or less collapsed, thin-walled cells and from the epidermal layer arise numerous non-glandular hairs, which are from 0.2 to 0.8 mm. in length, usually more or less bent, thin-walled, and slightly lignified at the base; in the rhaphe occurs a tangentially elongated fibro-vascular bundle having numerous spiral tracheæ; endosperm of from 9 to 30 rows of more or less polygonal cells with slightly thickened walls and containing small aleurone grains, a fixed oil, and strophanthin, the latter being colored bright green upon the addition of sulphuric acid; in the center occur two large plano-convex cotyledons having a distinct epidermal layer, a few fibro-vascular bundles and numerous parenchyma cells containing aleurone grains, a fixed oil, and occasionally a small amount of strophanthin. Sections of *S. hispidus* resemble those of *S. Kombe*, the hairs being fewer and the bases more strongly lignified. The powder is grayish-brown to dark brown; odor distinct; when examined under the microscope it exhibits chiefly thin-walled parenchyma cells and fragments of long, thin-walled hairs, the latter relatively few in *S. hispidus;* mounts made with hydrated chloral T.S. show numerous oil globules; upon the addition of sulphuric acid many of the fragments of the endosperm may be colored greenish. Strophanthus yields not more than 5 per cent. of ash." *U. S.*

The seeds of *S. Kombe* are described in the British Pharmacopœia as "oval, acuminate, about fifteen millimetres long and four millimetres broad; flattened, narrowed towards the base, which is obtuse; covered with silky appressed hairs; provided on one side with a longitudinal ridge running from the centre to the apex; of a greenish-fawn color. Kernel white and oily; cotyledons straight; endosperm narrow; in the seed-coats not more than an occasional crystal of calcium oxalate. Characteristic odor; taste very bitter. *Sulphuric acid* diluted with one-fifth of its volume of *water* colors the endosperm, and sometimes the cotyledons, dark green (presence of strophanthin)." *Br.*

Assay.—"For a method of assaying Strophanthus, see Biological Assays (Part III)." *U. S.*

The U. S. P. recognizes the biological assay as the only satisfactory method.

The Qualitative Examination of Strophanthus Seeds.—C. Hartwich (*A. Pharm.*, 1892) declares the usual course for the qualitative examination of strophanthus seeds—as the external appearance, the bitter taste, and the few chemical tests—insufficient, and recommends a microscopical test for strophanthin to supplement the usual tests. In the examination of a great variety of strophanthus seeds some were found to contain starch, which is rarely present in the commercial article.

For the valuation of the seeds the presence of strophanthin may be ascertained in the following manner. A thin cross-section of the seed is placed on a glass slide and covered with a drop of concentrated sulphuric acid. The endosperm at least should assume an intense green color, which is easily seen with a hand-glass. Often the green is preceded momentarily by a blue color. The cotyledons are also colored green, but generally less intensely than the endosperm. Gradually the color changes through blue into red, and after one-quarter to one hour it disappears. In seeds which contain but little strophanthin the endosperm alone is colored green, while the embryo is colored yellow and then red, or only the epidermis and the adjacent cells are colored in addition. For testing the tincture three drops are taken, and for the extract a piece a little larger than a pin head. In either case mix the drug with a half-drop of ferric chloride solution and three drops of sulphuric acid. A brown precipitate is formed which is distinctly green after one hour, and should retain the color for fully three hours.

Chemical Properties.—Hardy and Gallois obtained from strophanthus two crystalline principles. One, a glucoside, they call *strophanthin;* the second, an alkaloid, they name *inœine.* The first-named appears to be the active principle of the poison. (*J. P. C.*, 3e sér., xxv, p. 176.) T. R. Fraser describes more fully the glucoside strophanthin. (*P. J.*, 1886, July 23.) When heated with dilute sulphuric aicd it yields glucose and *strophanthidin,* which is insoluble in water, is very soluble in alcohol, and has a strongly bitter taste. In a subsequent study Fraser (*A. J. P.,*

1889, p. 532) has found strophanthin difficult to separate, but obtained it pure by a somewhat tedious process, depending upon the formation of a tannate and subsequent decomposition by lead oxide. It yielded upon analysis results corresponding to the formula $C_{30}H_{34}O_{10}$. Thoms (*Ber. d. Chem. Ges.*, 1898, 534) obtained pure strophanthin. Arnaud gives its formula as $C_{31}H_{48}O_{12}$; this was confirmed by Kohn and Kulisch and has been adopted by the French Codex. Feist gives its composition as $C_{40}H_{66}O_9$. Thoms found that the strophanthins as obtained from different species differ somewhat in chemical composition and properties and he proposes to designate them as follows: *k-strophanthin* when obtained from *S. Kombe; g-strophanthin* (*S. gratus*), *e-strophanthin* (*S. Emini*), *h-strophanthin* (*S. hispidus*). To g-strophanthin he gives the formula $C_{30}H_{46}O_{12} + 9H_2O$. G. strophanthin seems to be identical with *ouabain* (see *Acocanthera*, Part II). *Strophanthidin* has the formula $C_{23}H_{32}O_7 + 1\frac{1}{2}H_2O$. Strophanthidin, the product of decomposition of the glucoside, is described as having an intensely bitter taste and a neutral reaction, and as being very slightly soluble in water, moderately soluble in cold and freely in warm alcohol. It crystallizes with great readiness. No alkaloid was detected, but in the lead precipitate from an aqueous solution of the alcoholic extract a compound was found of strongly acid reaction and freely soluble in water, to which the name of *kombic acid* has been given. The experiments of Fraser have shown that the active principle of strophanthus is most abundant in the seeds, but that it is contained also in the follicles and the hairs. Pharmaceutical preparations of the drug should, therefore, be made from the separated seeds, while the pericarp and the hairs may be employed for the manufacture of strophanthin. For methods of assaying strophanthus see *D. C.*, 1900, 132.

After reviewing all of the proposed assay methods for this drug, Lampart and Mueller (*A. Pharm.*, ccli, 609) proposed a method based upon the preliminary extraction of the drug with absolute alcohol, the removal of oil from the percolate with petroleum ether, the conversion of the glucosides into strophanthidin by boiling with hydrochloric acid and the subsequent extraction with chloroform, weighing, and calculating to strophanthin by multiplying by the factor 2.187. The authors received the Hagen Bucholz prize of the German Apothecaries Society for this work.

Uses.—As was first shown by Thomas R. Fraser (*J. A. P.*, vii, p. 141), strophanthus belongs to that group of cardiac poisons of which digitalis is the type. Its effects upon the circulation are so similar to that drug (see page 408), that it is only necessary to note the points of difference. Strophanthus is somewhat more rapid in its action and decidedly less permanent than digitalis; it causes relatively less reduction of the pulse rate and is generally believed to have less influence on the vasomotor mechanism. It appears to be absorbed from the intestinal tract with much less regularity than digitalis and therefore is less certain in its effects. Besides its action upon the circulation, strophanthus has a marked influence on intestinal peristalsis, according to Magnus (*A. G. P.*, 1905, cviii, p. 1) causing increased peristalsis and tone and under certain conditions tetanic spasm of the intestines. Probably because of this action it frequently produces diarrhea when used clinically. According to the early researches of Fraser it exercises a similar influence on all forms of muscle tissue including voluntary muscles. It is by some believed that strophanthus has a direct stimulating effect upon the kidney and is superior to digitalis as a diuretic, but the evidence in favor of this view is far from convincing. While it possesses some local anesthetic powers it is so highly irritant that it is practically unavailable for this effect.

Strophanthus is used in medicine solely for its influence on the circulation, especially in cases of *chronic heart weakness*. It is of value in exactly the same class of cases in which digitalis is employed and, although more likely to cause digestive disturbances, is frequently useful as an alternative or adjuvant to that drug. By some it is believed to be especially indicated in those cases complicated with dropsies, because of a belief in a greater diuretic power. In cases of threatening urgency the effects of strophanthus upon the circulation can be obtained almost immediately by means of the intravenous injection of its active principle (see *Strophanthinum*).

The question of the relative variability of potency in strophanthus as compared to digitalis cannot as yet be definitely answered. Although certain German investigators have claimed that strophanthus is more subject to wide range in power, Hatcher and Bailey (*J. A. M. A.*, 1909, lii, p. 5) have found that the tincture of strophanthus is much more uniform in this country than the tincture of digitalis.

Dose, of strophanthus, one-fourth to one grain (0.016–0.065 Gm.).

STRYCHNINA. U. S., Br.

STRYCHNINE Strych.

(strȳch-nī'nạ)

"An alkaloid [$C_{21}H_{22}O_2N_2 = 334.20$] obtained from nux vomica, and also obtainable from other seeds of the *Loganiaceæ*. Preserve it in well-closed containers." *U. S.* "Strychnine, $C_{21}H_{22}N_2O_2$, is an alkaloid, obtained from the seeds of Strychnos Nux-vomica, *Linn.*, and other species of Strychnos." *Br.*

Strychnia, *U. S.* 1870; Strychninum; Strychnine, *Fr. Cod.*; Strychnin, *G.*; Stricnina, *It.*; Estricnina, *Sp.*

The U. S. and Br. Pharmacopœias very properly omit processes for preparing this alkaloid, as it can be made profitably only by the

manufacturing chemist on a large scale. (See U. S. D., 17th ed., p. 1295.)

J. F. Molyn proposed, previously to the extraction of strychnine, to subject nux vomica to fermentation, by which the saccharine and gummy matters of the seeds are decomposed, and lactic acid is formed, which decomposes the strychnine and brucine igasurates, producing with these bases very soluble lactates. For the particulars of this process, see *A. J. P.*, xix, 99, and for other processes see U. S. D., 14th ed., p. 1456.

The bean of St. Ignatius yields strychnine more easily and more largely than nux vomica. If thought desirable, brucine may be in great measure separated from the strychnine of commerce, by dissolving the latter in very dilute nitric acid, filtering, and concentrating. Brucine nitrate crystallizes in short, thick, dense prisms grouped together; strychnine nitrate in radiated tufts of long, light, capillary needles. By gentle agitation of the liquid, the latter salt is suspended and may be poured off, leaving the former. The alkaloids may be obtained by dissolving the salts in water, and precipitating with ammonia.

Properties.—As usually found in commerce, strychnine is a white or grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or rhombic prisms with pyramidal summits. It is officially described as in "colorless, transparent, prismatic crystals, or as a white, crystalline powder; odorless, permanent in the air. *Great caution must be used in tasting it and then only in very dilute solutions* which are exceedingly bitter. One Gm. of Strychnine dissolves in 6420 mils of water, 136 mils of alcohol, 5 mils of chloroform, and in 180 mils of benzene at 25° C. (77° F.); also in 3100 mils of boiling water, and 34 mils of boiling alcohol; very slightly soluble in ether. Its saturated solutions are alkaline to litmus and are lævorotatory. Sulphuric Acid containing 1 per cent. of ammonium vanadate produces with Strychnine a deep violet-blue color, changing to a deep purple, and finally to a cherry-red. A solution of about 0.1 Gm. of Strychnine in 2 mils of sulphuric acid is not more than pale yellow (*readily carbonizable organic impurities*), but on adding a fragment of potassium dichromate, a deep blue color is momentarily produced, changing to deep violet, then to purplish-red, cherry-red, and finally to orange or yellow. Incinerate about 1 Gm. of Strychnine; not more than 0.1 per cent. of ash remains. One mil of a mixture of equal volumes of nitric acid and distilled water, added to about 0.1 Gm. of Strychnine, may produce a yellow, but not a red or reddish color (*brucine*)." *U. S.*

"Colorless, transparent, prismatic crystals, permanent in the air. Very slightly soluble in *water*, but sufficiently soluble to impart an intensely bitter taste; soluble in about 150 parts of *alcohol* (90 per cent.). *Sulphuric acid* forms with it a colorless solution which, on the addition of *nitric acid*, acquires not more than a faint pink color (limit of brucine). When a small fragment is dissolved in 2 or 3 drops of *sulphuric acid* on a white porcelain plate and a crystal of *potassium bichromate* is slowly moved through the solution, an intense violet color is produced, passing to red and yellow. No appreciable ash." *Br.*

It melts like a resin, is decomposed at a comparatively low temperature, and entirely dissipated at a red heat. Guy obtained a crystalline sublimate, at a heat but a few degrees below that at which it begins to change color and undergo decomposition. Its melting point has been given as 284° C. (543° F.), but, according to Flückiger, in small portions it melts as low as 225° C. (437° F.) and can with care be sublimed without decomposition. According to Waddington, when heated to decomposition it emits a most suffocating odor, resembling the odor of asphaltum. (*P. J.*, March, 1868, p. 413.) Fused with an excess of potassium hydroxide, it yields, according to Goldschmied (*Ber. d. Chem. Ges.*, 15, p. 1977), *indol*, C_8H_7N, and when distilled with zinc dust it yields a *dimethyl pyridine*, C_7H_9N, and *carbazol*, $C_{12}H_9N$. The volatile oils dissolve it freely. Petroleum benzin dissolves 0.607 per cent. of it, and amyl alcohol 0.55 per cent. (Dragendorff, *J. P. C.*, 4e sér., iv, 473.) It has an alkaline reaction on test-paper, and forms salts with the acids. Nitric acid does not redden it if perfectly pure, but often reddens it as found in commerce, in consequence of the presence of brucine. Eugène Marchand proposed the following test by which a very minute proportion of strychnine may be detected. If a little of the alkaloid be rubbed with a few drops of concentrated sulphuric acid containing one-hundredth of nitric acid, it will be dissolved without change of color; but if the least quantity of lead peroxide be added to the mixture, a magnificent blue color will be instantly developed, which will pass rapidly into violet, then gradually to red, and ultimately become yellow. (*J. P. C.*, 3e sér., iv, 200.) Otto recommended as a test a minute quantity of solution of potassium dichromate, which, added to the solution of strychnine in concentrated sulphuric acid, produces a splendid violet color. (*A. J. P.*, xix, 77.) A similar change of color is produced, according to E. W. Davy, by substituting a strong solution of potassium ferricyanide (red potassium prussiate) for that of potassium dichromate. (*A. J. P.*, xxv, 414.) It appears that any substance capable of yielding nascent oxygen readily will serve to develop the characteristic violet color, when applied after the addition of sulphuric acid. According to Wm. Copney, the least efficacious agent is potassium chlorate, a much better is lead dioxide, a still better is manganese dioxide, and the best of all is potassium dichromate, and the general result of numerous experiments, recently made, is that the last-mentioned agent is the most effec-

tive. The sulphuric acid must be of not less sp. gr. than 1.84. The play of colors, according to Copney, is first blue, then purple, then crimson, which is followed by red and green, the latter sometimes giving place to yellow. It is stated that the 1-500,000th part of a grain may be detected. (See *A. J. P.*, xxviii, 459.) On the other hand, some chemists have found difficulties with the potassium dichromate test. Thus, Brieger (*Jahresb.*, 1850, p. 617) found that, unless the substance was first moistened with sulphuric acid and the dichromate added to it subsequently, the reaction of strychnine was interfered with by quinine, morphine, and especially by sugar. Sonnenschein (*Fresenius's Zeitschrift*, ix, p. 495) found that ceroso-ceric oxide was much more sensitive as a reagent to use with sulphuric acid for strychnine than potassium dichromate. This fact we can confirm from experience. It gives a blue color lasting longer, which then becomes violet, and then a permanent cherry-red. Vanadio-sulphuric acid (1 part of ammonium vanadate dissolved in 200 parts of pure sulphuric acid of 1.84 sp. gr.) is colored by strychnine at first violet-blue, passing into violet, and finally cinnabar-red. On dilution with water this color remains rose-red. According to Dragendorff, the color persists when as little as 0.001 milligramme of strychnine is used.

A reaction, more sensitive than the sulphuric acid and potassium dichromate test for detecting strychnine and sensitive to 0.01 Mgm. of the alkaloid, is proposed by G. Guerin (*P. J.*, xciii, p. 83) as follows: The alkaloidal residue is dissolved in 2 or 3 drops of sulphuric acid and then 2 or 3 Mgm. of manganese carbonate is added. On stirring, a blue color, gradually changing to violet and finally to pink, is produced. Landerer has found that solid iodic acid or potassium iodate heated gently with strychnine gives rise to a beautiful violet color, gradually passing to red, which remains unchanged for many days. (*A. J. P.*, March, 1861, p. 110.)

Wm. T. Wenzell states that, when very minute quantities of the alkaloid are being dealt with, much the best plan is to prepare a reagent by dissolving in 2000 grains of sulphuric acid one grain of potassium permanganate. The alkaloid, during the evaporation of its acidulated solution on the porcelain, collects in the margins of the film, and the smallest possible dot of the reagent is to be placed so that its margin comes in contact with that of the film. In this way, Wenzell affirms, he was able to detect 1-900,000th part of strychnine. (*A. J. P.*, xlii, 385.) Some doubt was thrown upon the value of this test by experiments which seemed to prove that the presence of morphine in excess, especially in connection with organic matter, so far modified or disguised the action of the test upon strychnine as to prevent the appearance of the characteristic color, but subsequent and carefully conducted experiments by Robert P. Thomas satisfactorily determined that the conclusions in relation to the effects of morphine were erroneous, and that whether alone or associated with organic matters, in small or in large quantity, it does not prevent the operation of this color-test if carefully applied. (*Am. J. M. S.*, Oct., 1861, and 1862, 1340; also *J. Am. C. S.*, 1894, No. 12.) J. U. Lloyd in his novel "Stringtown on the Pike" used in an interesting manner a color reaction which he had discovered that produced a color which might deceive some who were working on a toxicological investigation in strychnine poisoning. *Lloyd's reaction* consists in adding sulphuric acid to a mixture of 1 part of hydrastine and 4 parts of morphine and adding a little potassium dichromate in the manner in which the color test for strychnine is made; colors are produced which somewhat resemble those given by strychnine, but a careful toxicologist could not be deceived. A controversy ensued upon the announcement of the reaction, participated in by Williams, Mayer, Wangerin, Wharton, and others, the result of which proved that the value of the official color test of strychnine had not been seriously assailed. (See *D. C.*, 1901, 28, 48; Proc. *N. Y. State Pharm. Assoc.*, 1901, 252; *Amer. Drug.*, 1903, 66.)

Strychnine consists of carbon, hydrogen, nitrogen, and oxygen and has the formula $C_{21}H_{22}O_2N_2$. The salts of strychnine are for the most part soluble and crystallizable. Their solution is decomposed by the alkalies and their carbonates, and by tannic but not by gallic acid, and is not affected by ferric salts. They are precipitated by the solution of iodine in potassium iodide, and the precipitate, though soluble in alcohol, is insoluble in the diluted acetic and hydrochloric acid of the U. S. Pharmacopœia. (Fairthorne, *A. J. P.*, xxvii, 212.)

Strychnine is likely to contain impurities, of which the chief, besides brucine, are coloring matter and lime or magnesia. The two latter impurities are left behind when the adulterated alkaloid is incinerated in the open air. Pure strychnine leaves no ash under these circumstances. Brucine is detected by the red color which it yields with nitric acid. Neither this nor sulphuric acid colors strychnine—a test which distinguishes it from several other alkaloids.

Uses.—Strychnine is a stimulant to the whole central nervous system. The effects upon the brain are usually not well marked but in some individuals wakefulness often follows its use and the increased acuity of the special senses is further evidence of its stimulant action upon the cerebrum. The most direct symptom caused by strychnine is violent convulsions. These have been shown by McGuigan and Becht (*J. P. Ex. T.*, 1916, viii, 143), to be due to a simultaneous stimulation of both motor and sensory ganglia of the spinal cord. In the medulla the centers which show a special evidence of the stimulating effect of strychnine, are those governing respiration and vasomotion. While the increase in respiration caused by strychnine is not as great in the normal animal as after

some other drugs, it seems to possess an extraordinary power of overcoming the effects of depressant poisons. Clinically it is perhaps the most reliable respiratory stimulant which we possess. During the strychnic convulsion there is great rise in the blood pressure. This is due in large part to the violent spasm of the muscles and consequent asphyxia, but even when the convulsions are prevented by the previous injection of curare the drug still produces a distinct rise in the arterial pressure, indeed in doses too small to cause convulsions there is still evidence of a stimulation of the vasomotor center. The experiments of Pilcher and Sollman (*J. P. Ex. T.,* 1915, vi, p. 331), indicate that the effect is due largely to an increased irritability of the center so that it responds abnormally powerfully to any exciting influence. The effect of the drug upon the heart is not clearly understood. Although La Franca (*Z. E. P. T.,* 1911, ix, p. 436) found that strychnine increased the irritability and conductivity of the heart muscle the scientific evidence of any direct influence upon the heart is far from convincing. In large toxic dose strychnine causes a paralysis of the motor nerves similar to that produced by curare but it is improbable that this action can play any part in strychnine poisoning in the human being.

The convulsant effects of strychnine naturally suggest its use in *paralysis* but a moment's thought must convince anyone that in most forms of palsies it is incapable of benefit. When the loss of power depends upon the actual destruction of motor cells, as after apoplexy or poliomyelitis, it is evident that the drug can do no good because what does not exist cannot be stimulated. Or when there is a failure in the conducting power of the nerve, as in peripheral neuritis, it is equally manifest that excitation of the spinal cells is futile. Indeed in spinal paralyses much harm may be done by irritating the inflamed tissue in the neighborhood of the area of destruction. On the other hand when the paralysis is due to the effect of depressant poisons circulating in the blood, as, for instance, in certain types of *chronic lead poisoning,* strychnine may prove of the utmost value. Like other bitters strychnine improves the appetite and digestion, but it has been enormously misused as a "general tonic." It is to be remembered that strychnine is essentially a stimulant leading to an increased functional activity with an expenditure, rather than a storing up, of reserve power. Such slight tonic effects as it may possess are due to the improved digestion and circulation. There is a common belief among clinicians that strychnine increases the peristaltic activity of the intestinal tract and hence it is frequently added to laxative mixtures, but the experimental evidence on this point is contradictory.

As a circulatory stimulant strychnine is useful in a wide variety of conditions such as *surgical shock, collapse* from hemorrhage, *poisoning* by such depressants as ether, chloroform, or alcohol, and the adynamic stages of *infectious fevers.* In some forms of *chronic heart disease,* especially in *myocarditis,* despite the failure of pharmacologists to explain its modus operandi it seems to be clinically useful. Its value in *chronic bronchitis* in old and feeble subjects is probably also to be attributed to its effects upon the circulation. As a respiratory stimulant it is especially valuable in narcotic poisoning, as by opium or chloral. Strychnine is also asserted to be of much service in toxic *amblyopias,* especially that due to nicotine poisoning.

For ordinary purposes the dose of strychnine ranges from one-sixtieth to one-twentieth of a grain (0.0011–0.003 Gm.) but under many circumstances much larger quantities may be safely administered. Especially when used for its influence upon the circulation is it essential to give large doses. Many of the clinical reports of failure to influence the circulation with strychnine have doubtless been due to too small doses, thus Lucas (*American Journ. Dis. of Children,* 1914, vii) found that it required at least one-tenth of a grain to cause an appreciable change in the blood pressure. While others have reported distinct effects from somewhat smaller dose, the use of one-fortieth or one-thirtieth of a grain with the idea of having any marked influence upon the circulation is a delusion. In many cases it is essential to push the strychnine until marked exaggeration of the reflexes or even twitchings of the muscle afford a warning that the patient is approaching the toxic stage.

Poisoning.—The symptoms of strychnine poisoning come on usually with great suddenness and violence. Often without warning of any kind a patient falls in a violent convulsion. The convulsions are usually tonic in character, but are interrupted with periods of almost complete relaxation. They involve all the muscles of the body and are brought on by the slightest sensory impulses. During the spasm the body is rigid, usually arched backwards in the position of opisthotonos, the arms flexed, the face drawn into the *risus sardonicus.* Consciousness is not affected except as the result of the asphyxiation. During the period of convulsion the muscles of the chest are so firmly fixed that respiration is impossible and death may occur as the result of asphyxiation. In some cases, however, the fatal termination may be deferred for some hours and finally be the result of exhaustion. The ordinarily fatal dose probably lies between one-half and one grain, although much larger quantities may be recovered from under proper treatment. In the treatment of strychnine poisoning it is to be remembered that the convulsions are of reflex origin and therefore all manipulations which are capable of furnishing the sensory stimulus must be sedulously avoided. For this reason no attempt should be made to empty the stomach; death has occurred during a convulsion brought on by the effort to pass a stomach tube. As a chemical antidote potassium permanganate is

probably to be preferred, although Fantus (*J. A. M. A.*, 1915, lxiv) has reported favorable results in the lower animals from the use of Lloyd's reagent (silicated earth), and compound solution of iodine or tannic acid are also of value. The most important therapeutic measure is the control of the convulsions. For this purpose chloroform is probably the most efficient remedy. This drug should be administered to the stage of surgical anesthesia after which chloral hydrate and potassium bromide may be given to continue the sedative effect. Amyl nitrite is also a useful agent because of the rapidity of its action; during the height of the convulsion, when there is no respiration, 3 to 5 minims may be given hypodermically.

In an investigation of the members of the pyridine series of bases by C. Greville Williams and W. H. Waters (*Proc. Roy. Soc.*, xxxii, p. 162, 1881), they found that β lutidine (dimethyl-pyridine, C_7H_9N) was antagonistic to strychnine and an apparent antidote. When injected into frogs already under the influence of strychnine, it arrested the convulsions; or if given first and then followed by a fatal dose of strychnine, it prevented the appearance of the tetanus. (Blyth, *Poisons, their Effects and Detection*, 1884, p. 319.)

Strychnine should never be prescribed in liquid form in combination with bromides, iodides, or chlorides, for fear of forming the insoluble strychnine hydrobromide, hydriodide, or hydrochloride. Several cases of poisoning have occurred through neglect of this precaution. A. B. Lyons (*A. J. P.*, Oct., 1877) records a case of poisoning through the patient's receiving in the last dose the greater portion of the strychnine hydrobromide, which had crystallized out.

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

STRYCHNINÆ HYDROCHLORIDUM. Br.

STRYCHNINE HYDROCHLORIDE

(strȳch-nī'næ hȳ-drō-chlō'rī-dŭm)

"Strychnine Hydrochloride, $C_{21}H_{22}N_2O_2$,HCl,$2H_2O$, is the hydrochloride of the alkaloid strychnine." *Br.*

Strychninum Hydrochloricum; Hydrochlorate of Strychnine, *Br.*, 1885; Chlorhydrate de Strychnine, *Fr.;* Strychninhydrochlorid, Salzsaures Strychnin, *G.*

This salt of strychnine was made official for the first time in the Br. Ph. 1898; it is used in making *Liquor Strychninæ Hydrochloridi.* (See p. 661.) It is described as in "small, colorless, prismatic crystals. Soluble in 60 parts of *water.* Aqueous solution neutral to *litmus;* taste intensely bitter. Loses from 7 to 9 per cent. of its weight when dried at 110° C. (230° F.). Responds to the tests enumerated under 'Strychnina,' and yields the *reactions* characteristic of chlorides. No appreciable ash." *Br.*

In its physiological and therapeutic action, strychnine hydrochloride is equivalent to strychnine though slightly weaker.

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

Off. Prep.—Injectio Strychninæ Hypodermica, *Br.;* Liquor Strychninæ Hydrochloridi, *Br.*

STRYCHNINÆ NITRAS. U. S.

STRYCHNINE NITRATE Strych. Nit.

(strȳch-nī'næ nī'trăs)

"The nitrate [$C_{21}H_{22}O_2N_2.HNO_3 = 397.21$] of the alkaloid strychnine. Preserve it in well-closed containers, protected from light." *U. S.*

Azotate de Strychnine, *Fr. Cod.;* Nitrate de Strychnine, *Fr.;* Strychninum nitricum, *P. G.;* Strychninnitrat, Salpetersaures Strychnin, *G.;* Nitrato di stricnina, *It.*

Preparation.—This salt may be made by dissolving a sufficient quantity of the alkaloid strychnine in diluted nitric acid until it is neutralized, evaporating the solution and crystallizing the strychnine nitrate.

Properties.—It is officially described as in "colorless, glistening needles, or as a white, crystalline powder; odorless, permanent in the air. *Great caution must be used in tasting it and then only in very dilute solutions* which are exceedingly bitter. One Gm. of Strychnine Nitrate dissolves in 42 mils of water, 150 mils of alcohol, 50 mils of glycerin, and in 105 mils of chloroform at 25° C. (77° F.); also in 9 mils of boiling water and 77 mils of alcohol at 60° C. (140° F.); insoluble in ether. Its saturated aqueous solution is neutral or only slightly acid to litmus and is lævorotatory. A solution of the salt, when poured carefully into a test tube upon a layer of sulphuric acid containing diphenylamine in solution, develops a blue color at the zone of contact. When the salt is heated with hydrochloric acid, a bright red color is produced. In other respects it responds to the tests for identity and purity under *Strychnina.*" *U. S.*

Uses.—Strychnine nitrate has no advantage over the other soluble salts of strychnine.

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

Off. Prep.—Syrupus Phosphatum cum Quinina et Strychnina, *N. F.*

STRYCHNINÆ SULPHAS. U. S.

STRYCHNINE SULPHATE Strych. Sulph.

(strȳch-nī'næ sŭl'phās)

"The sulphate $[(C_{21}H_{22}O_2N_2)_2.H_2SO_4 + 5H_2O = 856.56]$ of the alkaloid strychnine. Preserve it in well-closed containers." *U. S.*

Strychniæ Sulphas, *U. S.*, 1870; Strychninum Sulphuricum; Sulfate de Strychnine, *Fr. Cod.*; Schwefelsaures Strychnin, Strychninsulfat, *G.*; Sulfato de estricnina, *Sp.*

Preparation.—A process for this salt is no longer official. Two forms of *strychnine sulphate* are known, the acid sulphate, or commercial sulphate, and the official or neutral sulphate. Commercial strychnine sulphate, $C_{21}H_{22}O_2.N_2H_2SO_4 + 2H_2O$, crystallizes in needles. The water is expelled at 150° C. (302° F.). To prepare the neutral sulphate $(C_{21}H_{22}O_2N_2)_2.H_2SO_4$, a solution of the acid sulphate is divided into two equal portions: one of these portions is precipitated by ammonia, and the precipitate is added to the other part of the solution and the mixture boiled. On cooling, the liquid deposits the neutral salt in transparent prisms containing 5 molecules of H_2O. The crystals melt and become anhydrous at 200° C. (392° F.). By the spontaneous evaporation of an aqueous solution of the salt, transparent pyramids belonging to the quadratic system are obtained. According to Rammelsburg, these crystals contain 6 molecules of H_2O. (*Ber. d. Chem. Ges.*, 1881, p. 1231; *N. R.*, Jan., 1882.)

Properties.—This salt is in "colorless or white, prismatic crystals or as a white, crystalline powder; odorless, and efflorescent in dry air. *Great caution must be used in tasting it and then only in very dilute solutions* which are exceedingly bitter. One Gm. of Strychnine Sulphate dissolves in 32 mils of water, 81 mils of alcohol and in 220 mils of chloroform at 25° C. (77° F.); also in 7 mils of boiling water and 26 mils of alcohol at 60° C. (140° F.); freely soluble in glycerin; insoluble in ether. Its saturated aqueous solution (1 in 50) is neutral or only slightly acid to litmus. Barium chloride T.S. produces in a solution of the salt a white precipitate, insoluble in hydrochloric acid. When dried to constant weight at 100° C. (212° F.) it loses not more than 11 per cent. of its weight. In other respects Strychnine Sulphate responds to the tests for identity and purity under *Strychnina*." *U. S.*

The chief advantage of this preparation over strychnine is its much greater solubility in water. Owing to the presence of sulphuric acid and water of crystallization in this salt, it contains but about 75 per cent. of strychnine, and the proportionate dose would be therefore somewhat greater than that of the alkaloid. For a process for making *strychnine arsenite*, see *U. S. D.*, 19th edition, page 1196.

Dose, one-sixtieth to one-fifteenth of a grain (0.0011–0.004 Gm.).

STYRAX. U. S. (Br.)

STORAX [Liquid Storax]

(stȳ'răx)

"A balsam obtained from the wood and inner bark of *Liquidambar orientalis* Miller (Fam. *Hamamelidaceæ*)." *U. S.* "Prepared Storax is a viscid balsam obtained from the wounded trunk of Liquidambar orientalis, *Mill.*, purified by solution in alcohol, filtration, and evaporation of the solvent." *Br.*

Styrax Præparatus, *Br.*; Prepared Storax; Styrax Liquidus, Balsamum Storacis, Balsamum Styracis, Balsamum Styrax Liquidus; Styrax liquide, *Fr. Cod.*; Styrax, *P. G.*; Storax, Flüssiger Storax, *G.*; Storace liquido, *It.*; Estoraque liquido, *Sp.*

All species of the genus Liquidambar as well as those of a related genus, *Altingia*, yield *storax*. The product most valued, however, is that obtained from *L. orientalis* Miller.

The *oriental sweet-gum* (*Liquidambar orientalis*) is a tree from twenty to forty feet high. The palmate leaves have each of their divisions obscurely three-lobed, and are serrate, perfectly smooth, bright green and shining on the upper and pale on the under surface. The tree is a native of Asia Minor, in the southwestern parts of which it forms large forests. It yields the so-called *liquid storax*.

According to the researches of Moeller, storax is a pathological rather than a physiological product; when the young wood is injured secretion reservoirs are formed in which the storax is produced. (*O. Z.*, 1.) In collecting the drug the outer bark is first heavily bruised, so as to injure the inner bark, and after a time the outer bark having been removed the inner bark is scraped off. According to Maltass, this inner bark is first pressed cold in horse-hair bags, after which hot water is thrown over the bags and they are again pressed. Lieutenant Campbell states that the inner bark is first boiled with water, and, a portion of the balsam which rises having been skimmed off, is then pressed so as to extract the remainder. The residuary bark, after expression, is dried in the sun, and employed in various parts of Turkey for fumigation. It is the drug known in commerce as *Storax bark* or *Cortex Thymiamatis*. (Hanbury, *P. J.*, 1857, xvi, 463.) The balsam is sent in casks to Constantinople, Smyrna, and other ports of the Levant.

Several kinds of storax have been described. The purest was the *storax in grains*, which was in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety, formerly called *styrax calamita*, from the circumstance, it is supposed, that it was brought wrapped in the leaves of a kind of reed, consisted of dry and brittle masses, formed of yellowish agglutinated tears, in the interstices of which was a brown or reddish matter. The French call it *storax amygdaloïde*,

This and the preceding variety had a pleasant odor like that of vanilla. Neither of them, however, is now found in the markets. It is probable that one or both of these varieties may have been the product of *Styrax officinale.* A third variety, which was formerly seen in commerce, *styrax calamita,* was in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. Upon exposure, it becomes covered upon the surface with a white efflorescence of styracin. It evidently consisted of sawdust, united with a portion of the balsam. As found in commerce, it was usually in the state of a coarse, soft, dark-colored powder, mingled with occasional light friable lumps of various sizes, and containing very little of the balsam. When good, it should yield, upon pressure between hot plates, a brown resinous fluid having the odor of storax. Hanbury states that some of this variety is prepared at Trieste, Venice, and Marseilles, by mixing the residue of the liquid-ambar bark remaining after expression, and reduced to coarse powder, with genuine liquid storax. (*P. J.,* April, 1863.)

American Storax, Liquidambar styraciflua, or *Sweet Gum* of our Southern States.—Its geographical range reaches into Mexico, and it yields a storax-like product in an abundance proportionate to the heat of the climate. A specimen from Guatemala is described by Flückiger and Hanbury as a yellow, opaque resin, of honey-like consistence, becoming transparent, amber-colored, and brittle by exposure to the air, and having a rather terebinthinous balsamic odor and but little taste. Sometimes it occurs as a thick golden-brown fluid. It contains cinnamic acid and styracin. (*A. J. P.,* 1874, p. 161.) It is soluble in alcohol, and has been gathered to a considerable extent in the United States for the preparation of chewing gum. The resins of *Liquidambar formosana* and *L. altigiana* are known in Eastern commerce. *Malay storax* is an aromatic resinous product obtained from the *Altingia excelsa* Noronha (*L. altigiana* Bl.) It is sometimes called *rasamala resin* and contains tannic acid besides a very minute amount of cinnamic and benzoic acids.

A fourth variety, which, under the name of *liquid storax,* is the one commonly used, is a semi-fluid, adhesive substance, brown or almost black upon the surface exposed to the air, but of a slightly greenish-gray color within, and of an odor somewhat like that of balsam of Peru, though less agreeable. It is kept in jars.

Properties.—The storax used by pharmacists should correspond to the following official description and tests: "Storax is a semi-liquid, grayish, sticky, opaque mass, depositing on standing a heavy, dark brown stratum; transparent in thin layers, and having a characteristic odor and an acrid taste. It is heavier than water. It is insoluble in water, but completely soluble (with the exception of accidental impurities) in an equal weight of warm alcohol; almost completely soluble in ether, acetone, benzene, or carbon disulphide. When heated on a water-bath, Storax becomes more fluid, and if it is then agitated with warm, purified petroleum benzin, the supernatant liquid, on being decanted and allowed to cool, is not darker than pale yellow and deposits white crystals of cinnamic acid and cinnamic esters. The separated crystals evolve the odor of benzaldehyde when heated with diluted sulphuric acid and potassium permanganate. Incinerate about 0.5 Gm. of Storax; not more than 1 per cent. of ash remains. Dissolve about 10 Gm. of Storax, accurately weighed, in 20 mils of hot alcohol; the undissolved residue, after washing it on a filter with hot alcohol and drying at 100° C. (212° F.), does not exceed 2.5 per cent. The combined filtrate and washings, after the evaporation of the alcohol at a temperature not exceeding 60° C. (140° F.) and drying the residue for one hour at 100° C. (212° F.), leave a brown, transparent, semi-liquid product representing not less than 60 per cent. of the weight of Storax taken; this product is soluble in ether, with the exception of a few flakes, but only partially soluble in purified petroleum benzin. Dissolve about 1 Gm. of Storax, purified as described above, and accurately weighed, in 50 mils of alcohol, add 0.5 mil of phenolphthalein T.S., and titrate with half-normal alcoholic potassium hydroxide V.S. The acid value so obtained is not less than 56 nor more than 85 (see Part III, Test No. 10). Mix about 1 Gm. of Storax, purified as described, and accurately weighed, in a 250 mil flask with 50 mils of purified petroleum benzin, add 25 mils of half-normal alcoholic potassium hydroxide V.S. and allow the mixture to stand twenty-four hours, with frequent shaking. Then add 0.5 mil of phenolphthalein T.S. and titrate with half-normal hydrochloric acid V.S. It shows a saponification value of not less than 170 nor more than 230 (see Part III, Test No. 9)." *U. S.*

"Brownish-yellow, viscous, transparent in thin layers. Entirely soluble in *alcohol* (90 per cent.) and in *ether.* Odor and taste agreeable and balsamic. Boiled with *solution of potassium chromate* and *sulphuric acid* it evolves an odor of benzaldehyde. Loses not more than 5 per cent. of its weight when heated in a thin layer on a water-bath for one hour. *Acid value* not less than 60 or more than 90; *ester value* not less than 100 or more than 146. Yields not less than 20 per cent. by weight of cinnamic acid when tested by the following process:—Dissolve 2.5 grammes of the Storax in 25 millilitres of *N/2 alcoholic solution of potassium hydroxide,* boil for one hour under a reflux condenser, neutralise with *N/2 solution of sulphuric acid,* remove the alcohol by evaporation, and dissolve the residue in 50 millilitres of *water. Shake* this aqueous solution with 20 millilitres of *ether;* after separation remove the ethereal layer, wash it with 5 millilitres of *water* and add the washings to the aqueous solution, rejecting the ethereal liquid. Acidify the aqueous solution with *diluted sulphuric acid* and shake it with four successive portions, each of 20 millilitres, of *ether.* Mix the ethereal solutions, wash with

a few millilitres of *water,* transfer to a flask and distil off the ether. To the residue add 100 millilitres of *water* and boil vigorously for fifteen minutes under a reflux condenser. Filter the solution while hot, cool to 15.5° C. (60° F.), and collect on a tared filter the crystals of cinnamic acid that have separated. Repeat the extraction of the residue with the filtrate at least three times, or until no more cinnamic acid is removed. Press the filter paper and crystals between blotting paper, dry in a desiccator over *sulphuric acid,* and weigh. Add to the weight of the crystals so ascertained 0.03 gramme (representing the average amount of cinnamic acid remaining dissolved in the aqueous liquid). The total weight is not less than 0.5 gramme." *Br.*

As found in commerce, storax is usually so much adulterated as to require purification before it can be used, and in both Pharmacopœias processes were formerly given. Whenever not originally pure enough for use, it should be dissolved in alcohol, the solution strained, and the alcohol distilled off to a certain extent, and then completely evaporated at a gentle heat. Among the substances used in the adulteration of storax is turpentine. To detect it Hager employed the following method. He liquefied the resin, in a tube, by means of a water bath, added half its volume of absolute alcohol, and hastened the solution by agitation; he then treated it with several volumes of benzin. This operation was repeated twice. The liquors obtained were then evaporated, in a tared vessel, and there was secured, for pure storax, a colorless residue (45 to 55 per cent.), with a light-blue opalescence; for that mixed with turpentine, a residue more considerable, yellowish, and having the terebinthinate odor. (*J. P. C.,* Fév., 1876, p. 161.) The quality of storax at present on the market appears to be very much inferior to what it was a few years ago. It is stated (*P. J.,* 1911, lxxxvii, p. 86) that whereas in 1907 the commercial storax averaged about 19 per cent. of cinnamic acid with an acid number of 68.9, that upon the market in 1911 contained only about 2.5 per cent. of cinnamic acid, and had an acid number around 100. It is not improbable that this deterioration is due to the extraction of cinnamic acid before it is marketed.

Storax melts with a moderate heat, and, when the temperature is raised, takes fire and burns with a white flame, leaving a light, spongy, carbonaceous residue. It imparts its odor to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Neumann obtained from 480 grains of storax 120 of aqueous extract, and from an equal quantity 360 grains of alcoholic extract. Containing volatile oil and resin, and yielding benzoic or cinnamic acid by distillation, it is entitled to rank as a balsam.

The most abundant constituent of storax is probably *storesin,* $C_{36}H_{55}(OH)_3$, discovered in 1877 by W. von Miller. This is present in two forms, designated respectively alpha and beta, both free and in the form of a cinnamic ester. Storesin is an amorphous substance, melting at 168° C. (334.4° F.), readily soluble in petroleum benzin. *Cinnamic esters of phenylpropyl, cinnamic ester of ethyl, cinnamic ester of benzyl,* and especially *cinnamate of cinnamyl,* $C_9H_7O_2$. C_9H_9, the so-called *styracin* of Bonastre, have also been observed. This last compound can be removed by ether, benzene, or alcohol after the separation from the resin of the cinnamic acid; it is insoluble in water, and volatile only in superheated steam. It crystallizes in tufts of long rectangular prisms, which melt at 38° C. (100.4° F.), but frequently do not solidify readily. By concentrated solution of potassium hydroxide, it is resolved into a cinnamate and cinnamic alcohol (*styrone*), $C_9H_{10}O$, which latter is not present in liquid storax. The yield of *cinnamic acid* varies from 6 to 12 per cent., or even, according to Löwe, as much as 23 per cent. of crystallized cinnamic acid can be obtained. The acid dissolves abundantly in ether, alcohol, or hot water, slightly in cold water; it is inodorous, but has an acrid taste. It fuses at 133° C. (271.4° F.), and boils at 290° C. (554° F.). Another minor constituent of storax is a fragrant substance melting at 65° C. (149° F.), and possessing the odor of vanillin, which Rump (*Ber. d. Chem. Ges.,* 1878, 1034) identified. Miller also shows that water removes from the drug a little free benzoic acid. There is further found in liquid storax a hydrocarbon, C_8H_8, first prepared by Simon in 1839, which exists in the resin as a liquid, and also in a polymeric form as a solid. The former, called *styrol, styrene,* or *cinnamene styrene,* has a sp. gr. of 0.924, and a boiling point of 146° C. (294.8° F.). It is a colorless, mobile liquid, possessing the odor and burning taste of liquid storax. It has since been formed synthetically, and has been recognized as *phenylethylene,* $C_6H_5.CH=CH_2$. When heated for a considerable time to 100° C. (212° F.), or for a shorter period to 200° C. (392° F.), it is converted without change of composition into the colorless, transparent solid *metastyrol,* which, unlike styrol, is not soluble in alcohol or in ether. Lastly, there has been found in liquid storax, by J. H. van t'Hoff (1876), about 0.4 per cent. of a pleasant-smelling lævo-rotatory oil of the formula $C_{10}H_{16}O$. (*Pharmacographia,* 2d ed., 274 and 275.) Tschirch and L. v. Itallie (*A. Pharm.,* Sept., 1901, 506) state that styrax contains free cinnamic acid, vanillin, styrol, styracin, cinnamic acid-ethyl ester, cinnamic acid-phenylpropyl ester and storesinol partly free and partly as cinnamic acid ester.

Uses.—Styrax is a stimulating expectorant and feeble antiseptic, which was at one time used in various *pulmonic catarrhs,* also in *gonorrhea* and *leucorrhea,* but at present is very seldom used except as a constituent of the compound tincture of benzoin. Externally, mixed with two or three parts of olive oil, liquid storax was found by H. Schultze, of Magdeburg, to be very effective as a local remedy in scabies.

Dose, ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Tinctura Benzoini Composita, *U. S., Br.*

SUCCI

JUICES

(sŭc'cī)

Sucs végétaux, *Fr.*; Pflanzensäfte, *G.*

Though introduced to professional notice by Squire in the year 1835, and subsequently used by many practitioners, the juices were recognized but once by the U. S. Pharmacopœia (1870). They consist of the expressed juices of fresh plants, preserved by the addition of one-third of their bulk of alcohol. Considering the great inequality in strength, and, of course, the uncertainty in operation, of fresh juices themselves, varying according to the soil, climate, mode of cultivation, season, and the age of the plant, it may be questioned whether they merit the prominence which has been given them in the past.

SUCCUS LIMONIS. Br.

LEMON JUICE

(sŭc'cus lĭ-mō'nĭs)

"Lemon Juice is the freshly expressed juice of the ripe fruit of Citrus Medica, *Linn.*, var. β Limonum, *Hook. f.*" *Br.*

Limonis Succus, *U. S. P. VIII;* Succus Citri; Suc de Citron (de Limon), *Fr. Cod.;* Citronensaft, Limonensaft, *G.;* Succo di limone, *It.;* Zumo de limon, *Sp.*

We are supplied with lemons and limes chiefly from the West Indies, the Mediterranean and California. Though the former of these fruits only is directed by the Br., lime juice is recognized by the N. F., and both kinds are employed indiscriminately for most medicinal purposes, and the lime affords a juice at least equal, in proportional quantity and acidity, to that obtained from the lemon.

The seed of the lime contains 58 per cent. of fixed oil, which is said to equal in flavor the best olive oil. Its tendency to resist rancidity is reputed to be very great. (*B. C. D.*, 1894, 411.) Lime juice is official in the N. F. IV under the title of *Succus Citri* (see Part II).

As lemons rapidly deteriorate on keeping, if exposed to the air, the suggestions of protecting them by dipping them in melted paraffin, or by using a varnish of shellac dissolved in alcohol, made by George Mee, of London, are not without value. Mee found that lemons thus covered with varnish continued sound for a period of many months. (See *A. J. P.*, 1866, p. 474.)

The juice is the part for which the fruit is most esteemed. It is sharply acid, with a peculiar grateful flavor, and consists chiefly of water, citric acid (from 6 to 10 per cent.), gum and sugar (from 3 to 4 per cent.), and inorganic salts (2.28 per cent.). It sometimes has in it a little volatile oil, derived by pressure from the rind. It is "a slightly turbid, yellowish liquid. Taste sharply acid. Specific gravity 1.030 to 1.040. 20 millilitres require for neutralisation not less than 20 and not more than 25.7 millilitres of *N/1 solution of sodium hydroxide*, corresponding to a proportion of not less than 7 and not more than 9 grammes of citric acid in 100 millilitres. The residue obtained on evaporation, dried at 110° C. (230° F.), yields not more than 3 per cent. of ash. 100 millilitres of Lemon Juice are neutralised by about 11.4 grammes of Potassium Bicarbonate, by about 9.5 grammes of Sodium Bicarbonate, and by about 16.5 grammes of Sodium Carbonate." *Br.*

The U. S. P. IX does not recognize lemon juice; the U. S. P. VIII provided the following tests: "It reddens blue litmus paper and should contain from 7 to 9 per cent. of citric acid. If a few drops of barium chloride T.S. be added to filtered Lemon Juice, no turbidity or white precipitate should be produced (absence of *sulphuric acid* or *sulphates*). If an equal volume of sulphuric acid containing a few drops of alcohol be added to Lemon Juice, and the liquid heated, no odor of acetic ether should be developed (absence of *acetic acid*). Upon the addition of solution of potassium acetate (1 in 3) and alcohol in excess, no white crystalline precipitate should form after allowing the liquid to stand fifteen minutes (absence of *tartaric acid*). At least 10 mils of normal potassium hydroxide V.S. should be required to neutralize 10 mils of Lemon Juice, phenolphthalein T.S. being used as indicator." *U. S. VIII.*

As lemons cannot always be obtained, the juice is often kept in a separate state, but, from its liability to spontaneous decomposition, it speedily becomes unfit for medicinal use, and, though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavor unaltered. One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression, until a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It will keep still better if the bottles containing the filtered juice be permitted, before being closed, to stand for fifteen minutes in a vessel of boiling water. Another mode is to add one-tenth of alcohol and to filter. The juice may also be preserved by concentrating it either by evaporation with a gentle heat, or by exposure to a freezing temperature, which congeals the aqueous portion and leaves the juice much stronger than before. When used, it may be diluted to the former strength, but though the acid properties are retained, bottled lemon juice is frequently found to be preserved with sulphur dioxide, which dissolves in it to form sulphurous acid. The presence of this preservative interferes with some of its pharmaceutical uses and such a product should not be employed for medicinal purposes. The flavor of the juice is found to have been deteriorated. Lemon syrup is another form in which the juice is preserved.

The proportion of citric acid in lemon juice varies greatly, ranging from 4.5 to nearly 9 per cent. Stoddart found the acidity to diminish rapidly with the advance of summer, with little change in the sp. gr. of the juice. (*P. J.*, Oct., 1868.) H. H. Robins, after examining large consignments of lemons, states that the average

yield of citric acid taken from a year's receipts was 35.23 grains in a fluidounce. (*C. D.*, 1896, 742.) A solution of tartaric acid in water, with the addition of a little sulphuric acid, and flavored with the oil of lemon, has been fraudulently substituted for lemon juice, particularly as an antiscorbutic on long voyages, for which purpose it is quite useless. An application of the test for tartaric and sulphuric acids will at once detect the fraud.

The proportion of citric acid in lime juice is required by the N. F. IV to be not less than 5 Gm. nor more than 10 Gm. to each 100 mils. It is required to be free from sulphuric acid, but is permitted to contain 0.04 Gm. of SO_2 in each 100 mils. Other preservatives are prohibited as are also artificial colors.

Uses.—Lemon juice is refrigerant, and, properly diluted, forms a refreshing and agreeable beverage in *febrile* and *inflammatory affections*. It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as albumen water, barley water, etc., usually administered in *fevers*. It is also much employed in the formation of those diaphoretic preparations known by the names of *neutral mixture* and *effervescing draught*. (See *Mistura Potassii Citratis*, p. 654.) One of the most beneficial applications of lemon juice is to the prevention and cure of *scurvy*, for which it may be considered almost a specific. For this purpose, ships destined for long voyages should always be provided with a supply of the preserved juice. In England every foreign-going ship is required by law to take such a supply of lemon or lime juice that every seaman shall have a daily allowance of an ounce after having been ten days at sea. Its antiscorbutic effects have been found to be due to the presence of one of a class of chemical activators called *vitamines*. It has been employed with advantage in *acute rheumatism* in doses of from one to four fluidounces (30–120 mils) from four to six times a day. Locally applied it acts as an astringent and has been used with benefit in *pruritus of the scrotum*, in *uterine hemorrhage* after delivery, in *sunburn*, and as a gargle in *diphtheritic sore throat*.

Off. Prep.—Syrupus Limonis, *Br.*; Trochiscus Acidi Carbolici, *Br.*

SUCCUS SCOPARII. Br.

JUICE OF BROOM

(sŭc'cŭs scō-pā'rĭ-ī)

Suc de Genet à Balais, *Fr.*; Besenginstersaft, *G.*

"Bruise fresh Broom Tops; press out the juice; to every three volumes of juice add one volume of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

In large doses this juice is prone to disturb the stomach and bowels. It is more appropriately used as an adjuvant to other diuretics than alone.

Dose, as a diuretic, one to two fluidrachms (3.75–7.5 mils).

SUCCUS TARAXACI. Br.

JUICE OF TARAXACUM

(sŭc'cŭs tą-răx'ą-cī)

Suc de Pissenlit, *Fr.*; Löwenzahnwurzelsaft, Löwenzahnsaft, *G.*

"Bruise Taraxacum Root; press out the juice; to every three volumes of juice add one volume of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

Dose, two fluidrachms to half a fluidounce (7.5–15.0 mils).

SULPHONETHYLMETHANUM. U. S. (Br.)

SULPHONETHYLMETHANE Sulphonethylmeth. [Trional]

(sŭl-phōn-ĕ-thўl-męth-ā'nŭm)

"Diethylsulphonemethylethylmethane [$C_8H_{18}S_2O_4$ or $(CH_3)(C_2H_5)C(SO_2C_2H_5)_2 = 242.28$]. Preserve it in well-closed containers." *U. S.*

"Methylsulphonal, or diethyl-sulphone-methyl-ethyl-methane, $C_8H_{18}S_2O_4$, is an oxidation product of the mercaptol resulting from the condensation of ethyl-methyl-ketone with ethyl-mercaptan." *Br.*

Methylsulphonal, *Br.*; Methylsulphonal; Trionalum; Diethylsulphone-methylethylmethane; Trional, *Fr. Cod.*; Diéthylsulfone-méthyléthyl-méthane, *Fr.*; Methylsulfonalum *P. G.*; Methylsulfonal, Trional, *G.*; Trional, *Sp.*

Preparation.—*Sulphonethylmethane* is made by passing hydrochloric acid gas to saturation through a mixture of ethyl mercaptan and methyl ethylketone, then oxidizing the condensation product (methyl-ethyl-ketone mercaptol) by treating it with a weak solution of potassium permanganate; the compound is purified by repeated crystallization from its solutions in boiling water.

Sulphonethylmethane (or trional) and tetronal are substances which are members of the group of disulphones to which sulphonal belongs and are respectively *diethylsulphon-methylethyl-methane* and *diethylsulphon-diethyl-methane*. Their relationship to sulphonal (diethylsulphondimethyl-methane) will be readily seen by a comparison of formulas.

Sulphonal.	Trional.	Tetronal.
$C\begin{cases}SO_2C_2H_5\\SO_2C_2H_5\\CH_3\\CH_3\end{cases}$	$C\begin{cases}SO_2C_2H_5\\SO_2C_2H_5\\CH_3\\C_2H_5\end{cases}$	$C\begin{cases}SO_2C_2H_5\\SO_2C_2H_5\\C_2H_5\\C_2H_5\end{cases}$

Properties.—It is officially described as in "colorless, lustrous, odorless, crystalline scales, which have a bitter taste in aqueous solution. One Gm. of Sulphonethylmethane dissolves in 200 mils of water at 25° C. (77° F.); more soluble in boiling water; soluble in alcohol or ether. Its saturated aqueous solution is neutral to litmus. It melts between 74° and 76° C. (165.2° and 168.8° F.); at a higher temperature it is decomposed with the evolution of sulphur dioxide. Heat about 0.1 Gm. of Sulphonethylmethane with an equal weight of powdered charcoal in a

dry test tube; the characteristic, unpleasant odor of mercaptan is developed. Incinerate about 2 Gm. of Sulphonethylmethane; not more than 0.05 per cent. of ash remains. About 1 Gm. of Sulphonethylmethane dissolved in 50 mils of boiling distilled water develops no odor. Ten mil portions of this solution, after cooling and filtering, when tested separately, show no turbidity at once on the addition of a few drops of barium chloride T.S. (*sulphate*) or a few drops of silver nitrate T.S. (*chloride*). Twenty mils of the cold filtrate from the preceding test does not at once decolorize 0.05 mil of tenth-normal potassium permanganate V.S. (*readily oxidizable impurities*)." *U. S.*

"A white crystalline powder; taste slightly bitter. Soluble in 320 parts of *water,* somewhat more soluble in dilute *alcohol.* Melting point from 76° to 76.5° C. (168.8°–169.7° F.). At a red heat it decomposes with evolution of sulphur dioxide. When heated with *anhydrous sodium acetate* hydrogen sulphide is liberated. When boiled with *water* no offensive odor is developed (absence of mercaptan and merceaptol). 100 millilitres of a cold saturated aqueous solution do not immediately decolorise 1 drop of an aqueous solution (1 in 1000) of *potassium permanganate* (limit of readily oxidisable substances). No appreciable ash." *Br.*

The name methylsulphonal certainly appears to be a misnomer, as the product differs from sulphonal by the substitution of an ethyl group for one of the two methyl groups of sulphonal.

Uses.—The group of sulphone derivatives was introduced into medicine by Baumann in 1892. Two of them are recognized by the Pharmacopœia, sulphonethylmethane and sulphonmethane. These compounds are depressants to the higher cerebral centers. Although when given in very large dose they produce in the lower animals paresis and tremors, in quantities anywhere approaching the therapeutic dose they have almost no effect on man save to produce sleep. They are both characterized by the slowness of absorption and persistence of their action, although sulphonethylmethane is not quite so slow in its effects as sulphonmethane.

While in single dose they are relatively safe somnifacients, when used continuously over long periods of time they give rise to serious forms of intoxication. This generally starts with constipation and vague neurasthenic pains. In the fully developed stage chronic sulphone poisoning is characterized by obstinate constipation with scaphoid abdomen, cramp-like pains in the extremities, ataxia, insomnia, and a peculiar discoloration of the urine which ranges from a faint pinkish hue to a deep port wine red. This discoloration is due to the presence of a pigment known as *hematoporphyrin,* which is probably derived from decomposition of the blood. The urine is also usually highly acid and may contain albumen and tube casts. The prognosis in chronic sulphone poisoning is always grave. In the treatment it is essential to open the bowels as promptly as possible; for this the most powerful purgatives are usually required, and their action may be assisted by high enemata. In order to hasten the elimination of the poison large quantities of water should be administered, both by mouth and by hypodermoclysis. The free use of alkalies has been recommended with the idea of correcting the acidity of the system; sodium bicarbonate may be added to physiological salt solution for hypodermic injection. Symptom treatment is rarely of any efficacy.

There appears to be no recorded case of fatal acute poisoning by trional. Sixty grains (3.9 Gm.) are said to have produced hematoporphyrinuria, but one hundred and twenty grains (7.7 Gm.) have been recovered from without very serious symptoms. Although trional is less prone than is sulphonal to cause chronic poisoning, a number of cases have occurred.

Sulphonethylmethane is used in medicine solely as a somnifacient. In doses of from fifteen to twenty grains (1.0–1.3 Gm.) it usually causes sleep in from a half to an hour without unpleasant after effects. It may be administered as a powder, stirred up in half a glass of water, or enclosed in a gelatin capsule.

Dose, ten to twenty grains (0.65–1.3 Gm.).

SULPHONMETHANUM. U. S. (Br.)

SULPHONMETHANE Sulphonmeth.

(sŭl-phōn-mĕth-ā'nŭm)

"Diethylsulphonedimethylmethane [$C_7H_{16}S_2O_4$ or $(CH_3)_2C(SO_2C_2H_5)_2 = 228.27$]. Preserve it in well-closed containers." *U. S.* "Sulphonal, or dimethyl-methane-diethyl-sulphone, $C_7H_{16}S_2O_4$, may be obtained by oxidising mercaptol." *Br.*

Sulphonal, *Br.;* Diethylsulphon-dimethyl-methane; Acétone-diéthylsulfone, *Fr. Cod.;* Sulfonalum, *P. G.;* Sulfonal, *G.;* Sulfonale, *It.;* Sulfonal, *Sp.*

Preparation.—This compound belongs to the class of disulphones, to which belong also trional and tetronal. (See page 1080.) It may be made by the following processes. When anhydrous mercaptan (ethyl sulphydrate) and anhydrous acetone are mixed and a stream of dry hydrochloric acid gas passed through, the liquid gradually becomes turbid and separates into two layers, the upper being mercaptol (dithioethyldimethylmethane, the lower, diluted hydrochloric acid. The mercaptol is separated, washed, and then oxidized with potassium permanganate, the liberated oxygen converting the mercaptol into sulphonal. It may also be prepared by the action of ethyl chloride on sodium thiosulphate, the resulting sodium ethyl thiosulphate being converted into ethyl mercaptan and acid sodium sulphate by the action of water. This conversion is made to take place in the presence of alcohol, hydrochloric acid, and acetone, the ethyl mercaptan being condensed to mercaptol, which is oxidized by potassium permanganate, sulphonal being the result. It forms heavy colorless prismatic crystals, melting at 125.5° C. (257.9° F.), which are not very soluble in cold water, but more readily in boiling water, and in alcohol and alcoholic ether. A

characteristic test is to fuse the sulphonal in a small dry test-tube, heat to about 280° C. (536° F.), and to the clear liquid add pyrogallic (or gallic) acid. The liquid becomes brown and gives off the characteristic odor of mercaptan or sulphur alcohol. Heating with potassium cyanide or even with powdered charcoal will effect the same decomposition.

Properties.—It is officially described as in "colorless, inodorous, and nearly tasteless prismatic crystals, or as a crystalline powder. One Gm. of Sulphonmethane dissolves in 365 mils of water, 60 mils of alcohol, 11 mils of chloroform, and in 64 mils of ether at 25° C. (77° F.); also in 16 mils of boiling water and 3 mils of boiling alcohol; soluble in benzene. It melts between 124° and 126° C. (255.2° and 258.8° F.). In other respects it responds to the tests for identity and purity under *Sulphonethylmethanum.*" *U. S.*

The British Pharmacopœia gives the following description:

"Colorless prismatic crystals. No odor; nearly tasteless. Soluble in 450 parts of cold *water,* in 15 parts of boiling *water,* and in 80 parts of *alcohol* (90 per cent.). Melting point 125° C. (257° F.). Aqueous solution neutral to *litmus.* When mixed with an equal weight of *potassium cyanide* and heated, the odor of mercaptan is evolved, and when to the solution of the product in *water* excess of *hydrochloric acid* and a few drops of *T. Sol. of ferric chloride* are added, a reddish color is developed. Evolves hydrogen sulphide when gradually heated with *anhydrous sodium acetate.* Yields no characteristic *reactions* for chlorides or sulphates. No appreciable ash." *Br.*

Uses.—The action of sulphonmethane upon the system is similar to that of sulphonethylmethane. It generally requires, however, somewhat larger doses to produce sleep and its effects come on more slowly. Although usually not followed by disagreeable after effects, there sometimes remains some mental confusion and lassitude the following day. For some unknown reason it does not act happily in cases of heart disease and there have been reported sudden deaths in patients suffering from cardiac weakness following the use of sulphonal. It is best administered in the form of a powder stirred up in a glass of hot water or milk; it should never be exhibited in pill form.

Because of the seriousness of the chronic poisoning by this drug (see under *Sulphonethylmethane*)—the mortality is upwards of 75 per cent.—and the insidiousness of its onset, sulphonal should never be used without interruptions for more than a week or ten days. Acute poisoning by sulphonal is rare, but Knapp has reported a case in which 450 grains produced death after unconsciousness lasting three days. Even after therapeutic doses occasionally a measles-like rash appears.

Dose, from ten to forty grains (0.65–2.6 Gm.).

SULPHUR LOTUM. U. S.

WASHED SULPHUR Sulphur Lot.

(sŭl'phŭr lō'tŭm)

"Washed Sulphur, when dried to constant weight in a desiccator over sulphuric acid, contains not less than 99.5 per cent. of S (32.07)." *U. S.*

Flores Sulphuris Loti; Soufre Sublimé Lavé, *Fr. Cod.;* Sulphur Depuratum, *P. G.;* Gereinigter Schwefel, Gereinigte Schwefelblumen, *G.;* Solfo sublimato e levato, *It.;* Azufre lavado, *Sp.*

* "Sublimed Sulphur, *one hundred grammes* [or 3 ounces av., 231 grains]; Ammonia Water, *ten mils* [or 162 minims]; Water, *a sufficient quantity.* Pass the sublimed sulphur through a No. 30 sieve, mix it thoroughly with *one hundred mils* [or 3 fluidounces, 183 minims] of water, add the ammonia water, and set the mixture aside for three days in a closed vessel, agitating occasionally. Then add *one hundred mils* [or 3 fluidounces, 183 minims] of water, transfer the mixture to a strainer, and wash the sulphur with water until the washings cease to impart a blue color to red litmus paper. Then allow it to drain, press the residue strongly, dry it rapidly at a moderate heat in a drying closet, pass it through a No. 30 sieve, and keep it in well-closed containers." *U. S.*

Sublimed sulphur is frequently contaminated with small quantities of sulphuric acid and other impurities, and the object of the ammonia in the above process is to neutralize the acid, the salt being subsequently washed out and to remove any arsenical contamination. (See *Sulphur Sublimatum.*)

Properties.—It is officially described as "a fine, yellow powder, without odor or taste. It responds to the solubility and identity tests under *Sulphur Sublimatum.* Agitate 2 Gm. of Washed Sulphur with 10 mils of distilled water and filter; the filtrate is neutral to litmus (*acid or alkali*). The amount of residue left after volatilizing or igniting a weighed portion of dried Washed Sulphur does not exceed 0.5 per cent. Digest 0.5 Gm. of Washed Sulphur for three hours with 10 mils of ammonia water, filter the liquid, and evaporate the clear filtrate to dryness on a water bath. Then add 1 mil of nitric acid, and again evaporate to dryness. This residue meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—When dried to constant weight in a desiccator over sulphuric acid and assayed by the method under *Sulphur Sublimatum,* it shows, in the dried product, not less than 99.5 per cent. of S.

"Each gramme of Washed Sulphur, previously dried, corresponds to not less than 7.243 Gm. of barium sulphate." *U. S.*

For description of chemical and therapeutic properties, see *Sulphur Sublimatum.*

Dose, one to three drachms (3.9–11.6 Gm.).

Off. Prep.—Pulvis Glycyrrhizæ Compositus, *U. S.;* Unguentum Sulphuris, *U. S.;* Sulphuris Iodidum, *N. F.;* Trochisci Sulphuris et Potassii Bitartratis, *N. F.*

SULPHUR PRÆCIPITATUM. U. S., Br.

PRECIPITATED SULPHUR Sulphur Præc. [Lac Sulphuris, Milk of Sulphur]

(sŭl'phŭr præ-cĭp-ĭ-tā'tŭm)

"Precipitated Sulphur, when dried to constant weight in a desiccator over sulphuric acid, contains not less than 99.5 per cent. of S (32.07)." *U. S.* "Precipitated Sulphur is obtained by the action of hydrochloric acid upon a solution prepared by boiling together sulphur and lime in water." *Br.*

Magisterium Sulphuris; Soufre précipité, *Fr. Cod.*; Lait de Soufre, *Fr.*; Sulfur præcipitatum, *P. G.*; Schwefelmilch, *G.*; Solfo precipitato, *It.*

* "Sublimed Sulphur, *one hundred grammes* [or 3 ounces av., 231 grains]; Calcium Oxide, *fifty grammes* [or 1 ounce av.,.334 grains]; Hydrochloric Acid, Water, each, *a sufficient quantity.* Slake the calcium oxide, and mix it thoroughly with *five hundred mils* [or 16 fluidounces, 435 minims] of water. Add the sublimed sulphur, previously sifted, and, after thorough mixing, add *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of water, and boil the mixture in a porcelain or glass vessel during one hour, stirring or agitating the mixture very frequently, and replacing the water lost by evaporation. Then cover the vessel, and permit the contents to cool and become clear by subsidence. Carefully draw off the clear solution, and filter the remainder. To the united liquids add gradually and with constant stirring hydrochloric acid, previously diluted with an equal volume of water, until the liquid is nearly neutralized, but still retains an alkaline reaction and a yellow color. Collect the precipitate on a strainer, and wash it until the washings are neutral to litmus and cease to give a precipitate upon the addition of ammonium oxalate T.S. Then dry the product rapidly, and keep it in well-closed containers." *U. S.*

The process for *precipitated sulphur* was not changed in the last revision. The Br. Pharm. in its official definition outlines the method used in the U. S. preparation.

In the U. S. process three molecules of calcium oxide react with six atoms of sulphur to form two molecules of calcium disulphide and one of calcium thiosulphate (hyposulphite);

$$3CaO + (S_2)_3 = 2CaS_2 + CaS_2O_3$$

On the addition of the hydrochloric acid, six atoms of sulphur are precipitated (four from the two molecules of calcium disulphide and two from the one molecule of calcium thiosulphate), and the calcium and oxygen unite with the hydrochloric acid, so as to form calcium chloride and water, according to the reaction:

$$2CaS_2 + CaS_2O_3 + 6HCl = 3CaCl_2 + 3H_2O + (S_2)_3$$

This rationale is not exactly applicable to the British process of 1885, in which the proportion of the sulphur to the lime employed was greater than in that of the U. S. Pharm., and on account of this greater excess of sulphur the reaction takes place as follows:

$$3CaO + (S_2)_6 = 2CaS_5 + CaS_2O_3$$

a calcium pentasulphide being formed. Hydrochloric acid is the most eligible precipitant for the sulphur, as it gives rise to calcium chloride, which is a very soluble salt and is easily washed away. Sulphuric acid is wholly inadmissible, as it generates calcium sulphate, which, from its sparing solubility, becomes necessarily intermingled with the precipitated sulphur. According to Schweitzer, the best material from which to precipitate the sulphur is potassium sulphide, formed by boiling sulphur with potassium hydroxide. Otto, of Brunswick, finds that potassium sulphide is likely to contain copper sulphide, and therefore he prefers calcium sulphide.

Properties.—Precipitated sulphur is in friable lumps, of a white color, with a pale yellowish-green tint, and consisting of finely divided particles slightly cohering, or, as officially described, is "a fine, amorphous powder, of a pale yellow color, without odor or taste. Agitate 2 Gm. of Precipitated Sulphur with 10 mils of distilled water and filter; the filtrate is neutral to litmus (*acid or alkali*). It responds to the solubility and identity tests under *Sulphur Sublimatum.* It is more readily and completely soluble in carbon disulphide than other forms of sulphur. The amount of residue left after volatilizing or igniting a weighed portion of dried Precipitated Sulphur does not exceed 0.3 per cent. Digest 1 Gm. of Precipitated Sulphur for three hours with 10 mils of ammonia water and filter the liquid. Evaporate the clear filtrate to dryness on a water bath, add 1 mil of nitric acid, and again evaporate to dryness. This residue meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—When dried to constant weight in a desiccator over sulphuric acid and assayed by the method under *Sulphur Sublimatum,* it shows, in the dried product, not less than 99.5 per cent. of S. Each gramme of Precipitated Sulphur, previously dried, corresponds to not less than 7.243 Gm. of barium sulphate." *U. S.*

"A greyish-yellow, soft powder, free from grittiness and from the odor of hydrogen sulphide. Under the microscope it is seen to consist of opaque globules, without any admixture of crystalline matter. Burns with a blue flame, forming sulphur dioxide, and leaving not more than 0.5 per cent. of fixed residue. When 10 grammes are mixed with *water,* filtered, and thoroughly washed, the mixed filtrate and washings require for neutralisation not more than 2 millilitres of *N/10 solution of sodium hydroxide* (limit of acidity). *Arsenic limit* 5 parts per million." *Br.*

The German test, that 1 Gm. of precipitated sulphur should dissolve in 5 Gm. of carbon disulphide, is trustworthy, according to Fittinger. Precipitated sulphur is entirely dissipated by heat; water boiled with it should not redden litmus. When recently prepared, it is devoid of

taste, but possesses a peculiar odor. When long exposed, in a moist state, to the air, it becomes strongly contaminated with sulphuric acid. From its color it was formerly called *lac sulphuris*, or *milk of sulphur*. It is insoluble in water, but dissolves in a boiling solution of potassium hydroxide, and in oil of turpentine by the aid of heat. When of a brilliant white color, the presence of calcium sulphate may be suspected, in which case the preparation will not be wholly volatilized by ignition. If pure, it communicates a harsh feel when rubbed between the fingers, owing to the friction of the particles. Precipitated sulphur differs from sublimed sulphur in being in a state of more minute division, and in its amorphous condition, sublimed sulphur being crystalline.

Colloidal sulphur, which is said to be physiologically much more active than ordinary sulphur, may be produced by passing H_2S into a solution of SO_2 and, after decantation, adding distilled water to the precipitated sulphur, which readily dissolves, and may be freed from SO_2 by subsequent dialysis. This aqueous solution contains about six grains to the fluidounce of colloidal sulphur.

Uses.—Precipitated sulphur possesses medicinal properties similar to those of sublimed sulphur. Its state of extreme division renders it more readily suspended in liquids. A form easily suspended in water may be prepared by adding to the calcium polysulphide solution a solution of casein. The precipitated sulphur carries with it a little casein which communicates through its colloidal effect suspending properties to the sulphur. It is sometimes selected for forming sulphur ointments; these are lighter in color and smoother than those made with sublimed sulphur.

Dose, one to three drachms (3.9–11.6 Gm.).

Off. Prep.—Confectio Sulphuris, *Br.;* Trochiscus Sulphuris, *Br.;* Pasta Betanaphtholis, *N. F.;* Pasta Zinci Sulphurata, *N. F.*

SULPHUR SUBLIMATUM. U. S., Br.

SUBLIMED SULPHUR Sulphur Sublim.
[Flowers of Sulphur]

(sŭl'phŭr sŭb-lĭ-mā'tŭm)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.5 per cent. of S (32.07)." *U. S.* "Sublimed Sulphur may be obtained from native sulphur or sulphides." *Br.*

Flores Sulphuris; Brimstone; Soufre Sublimé, *Fr. Cod.;* Fleur (Crême) de Soufre, *Fr.;* Sulfur sublimatum, *P. G.;* Schwefel, Schwefelblumen, Schwefelblüthe, *G.;* Solfo sublimato, *It.;* Azufre sublimado, Azufre, *Sp.*

Natural States.—Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and vegetable matter. Among vegetables, it is present in volatile oil of mustard and other cruciform plants. It occurs in the earth either native or in combination. When native it is found in masses, translucent or opaque, or in the powdery form mixed with various earthy impurities. In combination it is usually united with certain metals, as iron, lead, mercury, antimony, copper, and zinc, forming compounds called sulphides. *Native sulphur* is most abundant in volcanic countries, and is hence called *volcanic sulphur*. Productive mines of sulphur are found in Sicily, but the output has declined in recent years. In 1915 it was 334,974 metric tons. Sulphur exists as a mineral in widely separated localities and in quantities in the Western United States. Two hundred miles south of Salt Lake City there is a deposit of sulphur two thousand feet square and of an unknown thickness, shafts having been sunk sixty feet without reaching the bottom. This sulphur is said to be free from arsenic and antimony and is a surface deposit. Much sulphur has been found in Mount Humboldt, Nevada, and Sulphur Mountain, as it is called, in the Yellowstone National Park, is largely composed of the mineral. The only localities in the United States in which sulphur is actively mined at present, however, are in Calcasieu Parish, La., where the Union Sulphur Company is now operating on an extensive scale, and a sulphur deposit underlying a quicksand is being mined by the Frasch process, and at Freeport and other localities in Texas. A double-walled iron pipe is driven through the quicksand into the sulphur bed, and steam having been sent down between the walls of the pipe, the melted sulphur is raised in the inner pipe. An annual production of 375,000 tons is now maintained by the Union Sulphur Company, and this can be increased readily from the wells already opened. Sulphur exists in large quantities in various localities in Japan, and 24,647 tons from there was received in the United States in 1915 for consumption on the Pacific coast.

Sicilian sulphur is usually extracted from the sulphur-containing earth by heating in covered mounds known as *calcaroni*, and collecting the melted sulphur or by extraction from the earth by superheated steam under several atmospheres pressure. In Louisiana it is pumped from the wells in a melted state of 99.9 per cent. purity.

The process of purifying the crude Sicilian sulphur consists in distilling the crude sulphur from a large cast iron still, set in brickwork over a furnace and furnished with an iron head. The head has two lateral communications, one with a chamber of brick work, the other with an iron receiver immersed in water, which is constantly renewed to cool it sufficiently to cause the sulphur to condense in the liquid form. When the tube between the still and the receiver is shut, and that communicating with the chamber is open, the sulphur condenses on its walls in the form of an impalpable powder, and constitutes *sublimed sulphur*, or *flowers of sulphur*. If, on the other hand, the communication with the chamber be closed, and that with the receiver open, the sulphur will condense in the latter in the fused state, and, when cast in

cylindrical moulds, forms the *roll sulphur* of commerce.

In the island of Anglesea, and at Swansea, Wales, large quantities of sulphur are obtained from imported Spanish copper pyrites in the process for extracting the metal. The furnaces in which the ore is roasted are connected with chambers in which the volatilized sulphur is condensed.

A process for separating pure sulphur from the residue of the manufacture of soda (calcium sulphide), proposed by Max Schaffner, has been used in most of the soda factories of Germany, and has been introduced, to a greater or less extent, in England, France, and Belgium. We shall confine ourselves to an outline. The process is divided into three parts: *first*, the preparation of the *soda solution* by heaping up the soda residue in the air, whereby oxidation takes place, and polysulphides and thiosulphates are formed, which are extracted by lixiviation; *secondly*, the solution thus obtained is decomposed in close stone or iron vessels, by hydrochloric acid, which decomposes the polysulphides and thiosulphates, with precipitation of sulphur; and, *thirdly*, the sulphur is obtained pure by fusing it under water, with steam and a pressure of 1¾ atmospheres. Calcium chloride remains in solution, gypsum is suspended, and the addition of a little milk of lime neutralizes any free acid present, and with the sulphur forms calcium sulphide, which dissolves whatever arsenic sulphide may be present, leaving the sulphur free from impurities. This collects in the bottom of the kettle, and is drawn off into moulds. From 60 to 65 per cent. of pure sulphur is thus obtained from the soda residue. A. M. Chance (*J. Soc. Chem. Ind.*, 1888, p. 162) has described a process which after several years of experiment has been perfected, and seems likely to solve definitely the problem of sulphur recovery, if, as stated, 95 per cent. of the sulphur can be either recovered as brimstone or burned in sulphur furnaces for the manufacture of sulphuric acid. Chance passes limekiln gases (carbon dioxide and nitrogen) into the vats of alkali waste, liberating thereby the sulphur as hydrogen sulphide. This mixed with nitrogen goes into another vessel of alkali waste, when H_2S and CaS unite to form $Ca(HS)_2$, a calcium sulphydrate, while the nitrogen is allowed to escape. The $Ca(HS)_2$ is now decomposed by a fresh quantity of CO_2, and thus liberates a double quantity of hydrogen sulphide. This is so pure that when mixed with the requisite quantity of air and passed over anhydrous ferric oxide at a dull red heat the hydrogen is burned, liberating the sulphur, according to the reaction:

$$H_2S + O = H_2O + S$$

The sulphur can be obtained either in the sublimed or in the fused form, according to the temperature of the chamber.

Crude foreign sulphur has come to this country principally from Messina, in Sicily, and the ports of Italy, but in recent years Japanese sulphur has been received on the Pacific coast. Roll sulphur and the flowers are often brought from Marseilles. Good Sicilian sulphur does not contain more than 3 per cent. of impurity, consisting chiefly of earths. The Louisiana sulphur the extraction of which is described on page 1084 enters commerce, having the purity of 99.9 per cent. Crude sulphur is employed by the manufacturers of sulphuric acid, and, as it is very variable in quality, it becomes important to ascertain its value. This may be done by drying a given weight of it and submitting it to combustion. The weight of the incombustible residue, added to that lost in drying, gives the amount of impurity.

Properties.—Sulphur is a non-metallic element, existing in several allotropic states. In its ordinary state it is a brittle solid, of a pale yellow color, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible odor when rubbed. When pure its sp. gr. is about 2, but it varies a little in density in its different allotropic states. Occasionally, from impurity, its sp. gr. is as high as 2.35. It is a poor conductor of heat, and becomes negatively electric by friction. The melting point of sulphur varies with its allotropic state, which is readily altered by heat. Pure sulphur melts and sublimes at 114.5° C. (238° F.). If heated above its melting point, it undergoes, in proportion to the heat applied, a progressive change, which will cause it, upon slow cooling, to solidify at a temperature lower than that at which it was melted; and if it be remelted it will be found to have a higher melting point than before. Melted sulphur is perfectly limpid, and of a bright yellow color. When sulphur is melted, and, after partial cooling, the crust formed on its surface is pierced, and the fluid portion poured out, it may be obtained in slender monoclinic crystals, constituting an allotropic condition of the element. This variety, however, gradually passes back into the more permanent variety found in nature. When sulphur is heated above its melting point, it becomes deeper in color and less fluid. At 200° C. (392° F.) it has a deep brown color, and is so viscid that it cannot be poured from the containing vessel. If the temperature be still further increased, the sulphur resumes its fluidity, but retains its brown color. Finally, when the temperature reaches 448.4° C. (839° F.), it boils, forming a yellow vapor, and may be distilled. If melted sulphur, heated above 200° C. (392° F.), is suddenly cooled by being poured out into water, it becomes a reddish-brown plastic mass, with alteration of properties, called *soft sulphur* (*viscid sulphur*), which constitutes another allotropic variety, and is employed in taking impressions of medals, etc. This form of sulphur resumes the hard state, but not its original color, after the lapse of a few days, or suddenly if heated to 100° C. (212° F.). Sulphur is insoluble in water, but soluble in alkaline solutions, petroleum, rectified coal naphtha, the fixed oils, oil

of turpentine and other volatile oils, alcohol and ether, chloroform, and carbon disulphide. One of its best solvents is carbon disulphide, from solution in which it crystallizes generally in rhombic octahedra, forms belonging to a different system from the monoclinic prisms obtained by crystallizing melted sulphur by cooling. Hence sulphur is said to be dimorphous. Eugène Pelouze has observed that the oils obtained by distilling the tar from gas works dissolve most sulphur at a temperature near their boiling point, and, if a saturated solution at this heat were to be allowed to cool, it would deposit sulphur in a crystalline form, and M. C. Wiedmann has suggested the application of this property to extraction of sulphur from native sulphur earths and ores, and from the residue of coal-gas works. (*A. J. P.*, June, 1871, p. 267.)

The allotropic states of sulphur have been studied chiefly by Brodie, Magnus and Weber, and Berthelot. These states are induced, for the most part, by heat, and are distinguished by the crystalline form of the sulphur, and by its solubility or non-solubility in carbon disulphide. *Insoluble sulphur* is the name given to that part of the soft sulphur which is left undissolved by the disulphide, amounting to between one-third and nearly one-half of the former. Brodie was unable to determine the melting point of this sulphur, but found it considerably above 120° C. (248° F.), or the melting point of prismatic sulphur. Flowers of sulphur contain about one-third of their weight of insoluble sulphur.

According to Marès, sulphur mixed with calcium carbonate, in the presence of the organic matters of the soil, is converted at first into hydrogen sulphide, then, under the influence of air and porous bodies, into sulphuric acid, finally into calcium sulphate, but Egidio Pollacer, on the contrary, thinks that sulphur in contact with calcium carbonate passes very readily into sulphuric acid, and then to calcium sulphate, independently of organic matters, and without being preliminarily changed into hydrogen sulphide, and this opinion he supports by several experiments. (*J. P. C.*, Oct., 1874, p. 330.)

Sulphur takes fire at about the temperature of 148.8° C. (300° F.), and burns with a blue flame, combining with the oxygen of the air, and giving rise to sulphurous oxide, SO_2. The combinations of sulphur are numerous, and are among the most powerful chemical agents. It forms with oxygen four oxides, *sulphurous oxide* (*sulphur dioxide*), SO_2 *sulphuric oxide* (*sulphur trioxide*), SO_3, *sulphur sesquioxide*, S_2O_3, and *sulphur heptoxide*, S_2O_7. The first two of these oxides, by their union with water, form *sulphurous acid*, H_2SO_3, and *sulphuric acid*, H_2SO_4, respectively. There are also known *hyposulphurous acid*, H_2SO_2, the corresponding oxide of which is not known, and in combination *thiosulphuric acid* (frequently spoken of as hyposulphurous acid), $H_2S_2O_3$, *persulphuric acid*, $H_2S_2O_8$, and a series of acids, $H_2S_2O_6$, $H_2S_3O_6$, $H_2S_4O_6$, and $H_2S_5O_6$, called the *thionic series*. It forms with hydrogen, hydrogen sulphide (hydrosulphuric acid or sulphuretted hydrogen), and with the metals, various *sulphides*. Some of the sulphides are analogous to oxyacids, others to basic hydroxides; and these different sulphides, by combining with one another, form compounds which, from their analogy to salts, are called Berzelius *sulphosalts*.

Sulphur, when obtained by roasting the native sulphide, sometimes contains arsenic, and is thereby rendered poisonous. Sicilian sulphur, being volcanic, is not subject to this impurity. The common English roll sulphur is sometimes made from iron pyrites, and is then prone to contain orpiment (arsenic trisulphide). This impurity may be detected by heating the suspected sulphur with nitric acid. The arsenic, if present, will be converted into arsenic trioxide, and the nitric solution, diluted with water, neutralized with sodium carbonate, and acidulated with hydrochloric acid, will give a yellow precipitate of arsenic pentasulphide with a stream of hydrogen sulphide. A precipitate may be more readily obtained from the nitric solution if, after neutralization, sulphurous acid be added, which will convert the arsenic acid into arsenous acid. This is more easily decomposed by the hydrogen sulphide, but the precipitate obtained will now be the trisulphide. Sulphur, when perfectly pure, is wholly volatilized by heat, and soluble without residue in oil of turpentine. According to Playfair, a solution of sodium nitro-prusside is a delicate test for the alkaline sulphides, producing with them a violet tint. Bailey of West Point, employed the same test for detecting sulphur in any compound. The substance suspected to contain it is fused with sodium carbonate, with the addition of carbonaceous matter if necessary. If sulphur be present it will be converted into sodium sulphide, and upon the addition of a small portion of the fused mass to a drop of the nitro-prusside the characteristic violet tint will be produced.

Sublimed sulphur, usually called *flowers of sulphur* (*flores sulphuris*), is "a fine, yellow powder, having a slight, characteristic odor, and a faintly acid taste. Sublimed Sulphur is practically insoluble in water and nearly insoluble in alcohol; it is slightly soluble in ether; soluble or partially soluble in carbon disulphide, chloroform, or olive oil. At about 115° C. (239° F.) it fuses to a yellow, mobile fluid, which upon further heating becomes dark and viscid. In the air it burns to sulphur dioxide, characterized by its odor. The amount of residue left after volatilizing or igniting a weighed portion of well-dried Sublimed Sulphur does not exceed 0.5 per cent.

"**Assay.**—Transfer about 1 Gm. of Sublimed Sulphur, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, to a flask containing 50 mils of a 10

per cent. solution of potassium hydroxide. Boil the mixture until the liquid is of a transparent, golden-yellow color and then dilute it with distilled water to make a volume of exactly 250 mils. Oxidize 25 mils of this diluted solution by the addition of solution of hydrogen dioxide in excess (using about 50 mils), and heat on a water bath for thirty minutes. Then acidulate the liquid with hydrochloric acid, and dilute it with 100 mils of distilled water. Now heat it to boiling and add hot barium chloride T.S., in small portions, to the resulting liquid until no further precipitation takes place. Heat this mixture on a water bath for thirty minutes, collect the resulting precipitate on a filter, wash, dry, ignite, and weigh the barium sulphate. Carry out a blank determination, using the same amount of all of the reagents but omitting the Sulphur, and before making the final calculation deduct the amount of barium sulphate thus obtained from that obtained in the assay. It shows, in the dried product, not less than 99.5 per cent. of S.

"Each gramme of Sublimed Sulphur, previously dried, corresponds to not less than 7.243 Gm. of barium sulphate." *U. S.*

"A slightly gritty powder of a bright greenish-yellow color. Odorless and tasteless. Under the microscope it is seen to consist of irregular angular particles mixed with almost opaque globules. Burns with a blue flame, forming sulphur dioxide, and leaving not more than 0.25 per cent. of fixed residue. When 10 grammes are mixed with *water*, filtered, and thoroughly washed, the mixed filtrate and washings require for neutralisation not more than 5 millilitres of *N/10 solution of sodium hydroxide* (limit of acidity). *Arsenic limit* 5 parts per million." *Br.*

It is always contaminated with a little sulphuric acid, which is formed at the expense of the oxygen of the air contained in the subliming chambers. Accordingly, it always reddens litmus, and, if the acid is present in considerable quantity, sometimes cakes. It may be freed from acidity by careful washing with diluted ammonia water. (See *Sulphur Lotum.*)

Uses.—Elemental sulphur is free from local effect and is so insoluble that it cannot be absorbed, and hence exercises no effect upon the system. When taken into the alimentary canal, however, a portion of it unites to form hydrogen sulphide, which is an active agent. By virtue of its local irritant action upon the mucous membrane the latter substance provokes intestinal peristalsis and therefore sulphur exercises a laxative influence. The movements produced by it are soft, generally without griping, and it is a frequently used laxative in cases of *hemorrhoids*. A certain amount of the hydrogen sulphide formed may be absorbed; indeed it is asserted that the sweat of persons taking sulphur will cause a black deposit of sulphide upon silver coins. Although the therapeutic properties of hydrogen sulphide have not been clearly determined, sulphur has been widely used as an alterative, especially in *chronic rheumatism* and *gout*. Besides this, a portion of the sulphide will be eliminated through the mucous membrane of the respiratory tract and sulphur may therefore exercise a beneficial action in *chronic bronchitis* and *asthma*.

The most important uses, however, of sulphur are external. When brought in contact with the skin, especially in the presence of alkalies, a similar union of sulphur with hydrogen takes place as in the intestines. The alkaline sulphide thus formed is an active poison to various pathogenic parasites and sulphur is therefore a useful remedy in such diseases as *scabies*, *ringworm*, and *favus*. Besides this effect the sulphides by their local stimulating effect tend to overcome congestion in the skin and they have the power of softening the horny elements. For one or the other of these effects sulphur is a valuable remedy in a number of non-parasitic diseases of the skin, especially *acne*, *psoriasis*, *seborrhea*, etc. Locally it may be employed either in the form of a suspension or in an ointment in strengths of from 5 to 20 per cent. It is often incorporated in soaps. For local application the precipitated sulphur is the best because of its finely divided state. For internal administration either the washed or precipitated sulphur may be employed.

Under the names of *sulfidal* and *sulfoform* a soluble *colloidal sulphur* has been introduced. This is asserted by Joseph (*Derm. Cb.*, 1913) and others to be superior to the official sulphur in the treatment of skin diseases. It is used in strengths of from 2 to 20 per cent. See under *Sulphur Precipitatum* for method of preparation.

According to Hannon of Brussels, *soft sulphur*, recently prepared, possesses valuable therapeutic properties, not as a laxative, but as a stimulant to the circulation, lungs, and skin, far more active than ordinary sulphur. The *dose* of soft sulphur is from twenty to fifty grains (1.3–3.2 Gm.), given in the form of pill. It has also been successfully employed for filling the hollows of *carious teeth*. (*P. J.*, xvii, 330.) Sublimed sulphur has been used with extraordinary success in South Africa and the Philippines in the treatment of *amœboid dysentery*. It acts probably by killing the amœba. It may be given in divided doses up to two hundred grains (13 Gm.) a day.

Much sulphur is consumed in the arts, principally in the manufacture of gunpowder and of sulphuric acid.

Dose, one to three drachms (3.9–11.6 Gm.).

SUMBUL. U. S.

SUMBUL [Musk-root]

(sŭm'bŭl)

"The rhizome and roots of *Ferula Sumbul* (Kauffmann) Hooker filius (Fam. *Umbelliferæ*)." *U. S.*

Sumbul Radix, *Br.;* Racine de Sumbul, *Fr.;* Sumbulwurzel, Moschuswurzel, *G.*

Under the name of *sumbul* or *jatamansi,* a root has long been used in India, Persia, and other parts of the East, as a perfume, an incense in religious ceremonies, and medicinally. It was the root of a then unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the north and east of it, as Nepaul, Bootan, Pucharia, etc. The root is taken northward to Russia, and reaches the rest of Europe through Petrograd. The physicians of Moscow and Petrograd were the first to employ it on the continent of Europe. Granville first introduced it to the notice of the profession in Great Britain and in this country. It has also been imported into England from India, whither it was brought from a great distance. The plant which is now recognized by the U. S. P. as the source of the sumbul is the *Ferula Sumbul* Hooker fil.

Ferula Sumbul was first discovered by the Russian Fedschenko in 1869, growing at an elevation of 3000 feet in the mountains which separate Russian Turkestan from Bucharia. In 1871 it was described by Kauffmann, who erected a new genus on characters dependent upon the enormous size of the vittæ in the immature fruit. The plant has been cultivated in the Moscow botanical gardens, and, less successfully, at Kew, and it has been found that the vittæ almost disappear in ripening, and do not afford a good generic character. The plant is a large umbellifer, reaching a height of eight feet, and having a solid, cylindrical, slender stem, which in the upper part gives origin to about twelve slender divaricate branches. The root-leaves are two and a half feet long, with short, channelled, broadly dilated, completely clasping petioles. They are triangular in outline, tripinnate, with the alternate divisions fine. The stem-leaves rapidly decrease in size until they become mere sheathing bracts. The flowers are polygamous, the fruit from three-eighths to one-half inch long by one-fourth inch wide; the mericarps oblong-oval, dorsally much compressed, thin, with three faint, thread-like, dorsal ridges; no dorsal vittæ, and commissural ones collapsed. J. E. Aitchison states (*Tr. Linn. Soc.,* ser, 2, *Bot.,* 69) that the root of *Ferula suaveolens,* which has only a faint musky odor, is one of the kinds exported from Persia to Bombay by the Persian Gulf.

Properties.—Sumbul is officially described as "in transverse segments, attaining a length of 10 cm. and a diameter of 7 cm.; externally light brown to dark brown, longitudinally wrinkled and showing in the upper portions a smooth, grayish, epidermal layer, occasionally with the short stem-bases attached; fracture short, fibrous, spongy; internally light yellow or brownish-yellow, arrangement of wood irregular and with yellowish-brown or blackish resinous patches frequently extending over the entire ends of the segments; odor peculiar, musk-like; taste bitter and somewhat aromatic. The powder is grayish-brown; when examined under the microscope it exhibits numerous, irregular, brownish-black fragments and well-defined isolated tracheæ, the latter with distinct end-walls, and mostly with reticulate thickenings and from 0.03 to 0.1 mm. in width; occasional fragments of polygonal epidermal cells with yellowish-brown walls; numerous, nearly colorless, yellowish-brown and reddish-brown fragments consisting of a granular substance in which the cellular structure is not well defined; long, narrow fragments consisting of more or less collapsed leptome or sieve tissue; occasional fragments of well-defined parenchyma with a few, nearly spherical starch grains, from 0.003 to 0.012 mm. in diameter." *U. S.*

The root has been analyzed by Reinsch and other German chemists, and found to contain volatile oil, two balsamic resins, one soluble in alcohol, the other in ether; wax, gum, starch, a bitter substance soluble in water and alcohol, and an acid which was named *sumbulic acid,* but which Riecker and Reinsch showed to be *angelic acid,* $C_5H_8O_2$, accompanied by a little valeric acid, $C_5H_{10}O_2$. Solution of potassium hydroxide is said to convert the resin into the potassium salt of an acid called *sumbulamic,* but which has not been sufficiently investigated. The musk-like odor seems to be connected with the balsamic resins, and probably depends on some principle associated with them not yet isolated. The volatile oil, of which 0.33 per cent. is yielded by distillation, has a taste like that of peppermint. On dry distillation it yields a bluish oil which contains *umbelliferone.* Philip H. Utech (*A. J. P.,* 1893, p. 465) has extracted and purified the resin soluble in alcohol. He obtained it as a soft, whitish, translucent resin which, on drying at 110° C. (230° F.), yielded a clear, transparent, amber-colored product having a bitter taste and the aromatic odor of the root. It constituted 6.1 per cent. of the drug. J. H. Hahn (*Proc. Penna. Ph. Assoc.,* 1896, 75) found 17.25 per cent. of fixed oil in sumbul.

A proximate analysis reported by Heyl and Hart (*A. J. P.,* Dec., 1916, p. 546, shows the following results: Moisture, 10.17 per cent.; starch, 7.70 per cent.; pentrosans, 10.60 per cent.; crude fiber, 17.15 per cent.; protein, 5.50 per cent.; dextrin, 1.40 per cent.; ash, 6.50 per cent.; sucrose, 1.64 per cent.; reducing sugar, 0.51 per cent., volatile oil, 1.10 per cent.; resins, 17.1 per cent. Alkaloids were not detected. The volatile oil did not show the presence of sulphur. *Umbelliferon* was detected, as was also

betaine. Vanillic acid ($C_8H_8O_4$) was identified in the resinous portion and a phytosterol was also recognized as being present. Acetic, butyric, angelic and tiglic acids were among the volatile acids, while among the non-volatile acids were oleic, linoleic, tiglic, cerotic, palmitic and stearic.

Uses.—Sumbul is supposed to have a quieting influence on the nervous system and is used in the treatment of various *hysterical* conditions. By many it is believed to have an especial relation to the pelvic organs and it is widely employed in *dysmenorrhea* and allied disorders. It has also been used as a stimulant to mucous membranes not only in *chronic dysenteries* and *diarrheas,* but in *chronic bronchitis,* especially with *asthmatic* tendency, and even in *pneumonia.*

Murawieff, of Russia, prepares the resin, which he considers to be the active principle, by macerating the root first in water, and then in a solution of sodium carbonate, washing it well with cold water, drying it, treating it with alcohol, filtering the tincture, adding a little lime and again filtering, separating the lime by sulphuric acid, agitating with animal charcoal, again filtering, distilling off nearly all the alcohol, mixing the residuum with water, driving off the remaining alcohol, and, finally, washing the precipitate with cold water, and drying it.

Half an ounce of a tincture produced narcotic symptoms, such as confusion of the head, a tendency to snore, even when awake, feelings of tingling, etc., with a strong odor of the medicine from the breath and skin, which continued for a day or two and gradually passed off. (*N. R.,* Oct., 1874, p. 309.)

Dose, one-half drachm to two drachms (2.0–7.7 Gm.).

SUPPOSITORIA. U. S.

SUPPOSITORIES

(sŭp-pŏs-ĭ-tō′rĭ-ă)

Suppositoires, *Fr. Cod.;* Suppositoria, *P. G.;* Suppositorien, Stuhlzäpfchen, *G.;* Supositorios, *Sp.*

Suppositories are solid bodies usually intended to be introduced into the rectum with a view either of evacuating the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighboring parts or on the system at large. Suppositories are also made for vaginal or urethral administration. They fulfil the same indications as enemata, and are sometimes preferable from the facility of their application, and, when the object is to produce the peculiar effect of a medicine, from the smallness of their bulk, which facilitates retention. Their form may be cylindrical, conical, or spherical, the last being preferable when the bulk is small, or they may be in the shape of the modified cone with a tapering base, as recommended by H. S. Wellcome. (*Proc. A. Ph. A.,* 1893, p. 103.) They should be of such a consistence as to retain their shape, but so soft as to incur no risk of wounding the rectum. For laxative purposes the suppository may be from one to three inches long, and about as thick as a common candle; with a view to the specific effects of medicines it should be considerably smaller, as in this case it is important that the medicines should be retained and the irritative influence of distention avoided. Soap is not unfrequently employed in this way as a laxative. A. B. Taylor, of Philadelphia, in 1852 called attention to cacao butter as the best base for suppositories, having more exactly the requisite degree of consistence and fusibility than any combination of suet, spermaceti, wax, etc., that could be employed. (*A. J. P.,* 1852, p. 211.) Experience has proved the correctness of his views. It has been thought necessary to use wax, spermaceti, or some other substance having a comparatively high fusing point, in order to render the suppository sufficiently firm. Continued experience has, however, demonstrated that, except in the warmest weather, or in the case of camphor, phenol, the essential oils, and similar medicinal substances, even the commercial cacao butter will suffice. It is said that cacao butter is usually adulterated with some other fat which melts at a low temperature, and that if a pure article can be obtained any substance to increase its hardness is never required. When such a material is employed, wax is usually selected, although cetaceum is preferable. If not more than 10 per cent. of the spermaceti is added, the value of the suppository is not very materially affected, although it melts more slowly, and consequently requires a longer time to act, than when the butter of cacao is used alone. Suppositories containing a considerable percentage of wax melt so slowly in the rectum as to be comparatively useless, or they may fail altogether to soften down, and be finally passed from the anus unchanged.

A critical study and contribution to the literature of suppository bases has been published by Bruno Solomon (*Ph. Ztg.,* 1913, p. 502), who classifies them in general as (1) cacao butter, (2) fat and wax combinations, (3) glycerin and gelatin, agar, soap, etc. He prepares what he calls a *mother mass* of gelatin 50, distilled water 100, and glycerin 100. From this, modifications with agar-agar and soap, etc., may be subsequently prepared with the minimum of effort.

A very good method of mixing the oil of theobroma with the hardening material is by grating with an ordinary tin grater, such as used in kitchens, and mixing the coarse powders before melting, and W. G. Ewing has proposed rubbing the powders and the medicinal substance in a mortar together, dividing the plastic mass, and shaping it with the fingers. It is better to shape them with a spatula, and roll them upon a pill tile with a little lycopodium. This plan, although having its advantages, is, however, not equal to the official one of melting the ingredients and running them

into moulds. Extemporaneous moulds, made by rolling paper into cones about an inch long, may be used, but are much less convenient than permanent metallic moulds. The tendency of the hardened suppositories to adhere to the moulds may be overcome more or less perfectly by dusting the moulds with lycopodium powder, or greasing them well with olive oil, but it is far better to rely upon the natural contraction of the mass, caused by thoroughly cooling the moulds. Wm. B. Addington (*A. J. P.*, 1873, p. 257) advises lining the moulds with tin foil. The difficulty may also be met by the use of moulds that open lengthwise, which are now used almost exclusively in preference to individual moulds, and Chas. E. Dwight commends very highly the substitution of plaster of Paris moulds for the metallic ones commonly employed. The mould must be very cold, so as to chill the melted liquid at once and prevent any separation of its ingredients by gravity. It has been proposed to condense the powdered ingredients of suppositories in a cold mould. (*A. J. P.*, 1875, p. 79.) It has also been recommended to form the excipient into the required shape, and then, while it is still soft, make an excavation from the base upward, into which the medicine may be introduced, and afterwards enclosed by a little of the cacao butter. But, as one of the objects of the excipient is an equable diffusion of the medicine, to prevent irritation, this method would be inapplicable to substances in any degree locally irritant.

J. Percy Remington has devised a suppository mould made of soft vulcanized rubber, it is used in the same manner as that employed for a metal mould, the advantage being mainly the facility of removal when the suppository is cold, a slight pressure with a twisting motion causes the soft rubber mould to open, and the suppository to drop out easily. (*Proc. New Jersey Pharm. Association*, 1906.)

The inventive genius of pharmacists has been industriously applied to the construction of suppository moulds, and there are now many varieties; the principle is much the same in all, however, but for convenience they may be classed as follows: 1. Individual moulds; these were among the first to be used. Half a dozen conical, hard-metal moulds, or made of paper, tin-foil, etc., are retained in an upright position in a tray containing ice-water. (See *A. J. P.*, 1861, p. 5; 1863, p. 228; 1867, p. 121; 1868, p. 52; 1870, pp. 296, 392; *Proc. A. Ph. A.*, 1902, 501.) 2. Moulds which consist of two solid pieces of metal, hinged or temporarily joined, so that when the suppository is thoroughly cooled the parts may be separated and the suppository dropped out. (See *A. J. P.*, 1871, pp. 488, 563; 1874, pp. 192, 246; 1875, pp. 98, 202; 1877, p. 569; 1879, pp. 184, 277; and *Proc. A. Ph. A.*, 1893, p. 103; 1902, 757.) 3. Soft rubber moulds. (See *Proc. New Jersey Pharm. Assoc.*, 1906.) 4. Moulds designed to be used through compression; more or less powerful. (*N. R.*, June, 1879, Jan. and March, 1880; also *Proc. A. Ph. A.*, 1897, p. 442.)

The weight—*i.e.*, the size—of rectal suppositories should vary according to the purposes for which they are employed. When they are to be used for infants and children, they should weigh from five to ten grains. The Br. Pharm., in conformity with the recommendation of H. B. Brady (*P. J.*, 1866, p. 544; 1868, p. 321; and 1871, pp. 193, 488, 563), adopts the weight of fifteen grains. Experience has shown this to be the most useful size, and the U. S. P. 1880 adopted it, but the U. S. P. (9th Rev.) directed the weight to be thirty grains. The papers of Brady upon the subject of suppositories may be consulted with advantage; also a series of articles by several other authors in *A. J. P.*, 1871.

The U. S. P. IX directs as follows: "Suppositories are solid bodies of various weights and shapes, adapted for introduction into the different orifices of the human body, and melting or softening at body heat. The vehicles usually employed are oil of theobroma, glycerinated gelatin, or sodium stearate. For suppositories made with oil of theobroma the following general processes may be employed: Take of the Medicinal Substance, *the prescribed quantity;* Oil of Theobroma, grated, *a sufficient quantity.* Reduce the medicinal substance, if dry, to a very fine powder, or, if an extract, soften it with an appropriate liquid, then mix it thoroughly in a mortar with about an equal weight of grated oil of theobroma, and incorporate the remainder of the oil of theobroma until a homogeneous, plastic mass is obtained, adding, if necessary, a small quantity of expressed oil of almond. Roll the mass on a graduated tile until a cylinder of the proper length is formed, divide this into the required number of equal parts, and with a spatula, or other mechanical aid, form them into the desired shape. If the process of cold compression is preferred, mix the medicinal substance in a suitable mortar with about an equal weight of grated oil of theobroma, as above directed, then thoroughly incorporate it with the remainder of the oil of theobroma, previously finely grated, chilling the mortar, if necessary, to preserve the pulverulent form of the mixture. Transfer the powdered mass to the cylinder of an appropriate suppository compresser and by the use of this apparatus prepare the desired number of compressed suppositories. If the process of fusion is preferred, mix the medicinal substance with about an equal weight of grated oil of theobroma, as above directed, then thoroughly incorporate it with the remainder of the oil of theobroma, previously melted by a gentle heat, in a suitable vessel provided with a lip; then allow it to cool to about 38° C. (100.4° F.), and, when the mixture begins to congeal, pour it immediately into suitable well-cooled moulds. Keep the moulds at a freezing temperature until the suppositories have hardened and are ready to be removed. For suppositories containing hydrated

chloral, phenol, or other substances which soften the vehicle, raise the melting point of the oil of theobroma by the addition of from 10 to 15 per cent. of spermaceti, but the melting point must not be raised above 37° C. (98.6° F.). For suppositories made with glycerinated gelatin the following process may be used: Take of the Medicinal Substance, *the prescribed quantity;* Glycerinated Gelatin, Glycerin, Water, each, *a sufficient quantity.* Mix the medicinal substance, if solid and soluble in water or glycerin, or if a miscible liquid, with a little water, and add sufficient glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it at once into suitable moulds which have been greased with a small quantity of petrolatum. Cool the moulds thoroughly before removing the suppositories. Moulds for urethral suppositories should be warmed sufficiently before pouring the mass to facilitate the proper filling of the mould. Suppositories having a firmer consistence may be prepared by substituting mucilage of acacia for a portion of the water or glycerin. If the medicinal substance is insoluble in water or glycerin, thoroughly levigate it in a warm mortar with a sufficient quantity of glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it into suitable moulds as above directed. With bulky powders about one-half of the glycerin may be replaced with water before levigation. Glycerinated gelatin suppositories should be protected against the effects of heat, moisture and dry air by keeping them in tightly-closed containers in a cool place. *Rectal Suppositories* should be cone-shaped, and when made from oil of theobroma should weigh about *two grammes. Urethral Suppositories (Bougies)* should be pencil-shaped, pointed at one extremity, and either *seven centimeters* in length, weighing about *two grammes,* or *fourteen centimeters* in length, weighing about *four grammes,* when made with glycerinated gelatin. If prepared with oil of theobroma they should weigh about one-half the above quantities. *Vaginal Suppositories* should be globular or oviform in shape, and weigh about *ten grammes* if made with glycerinated gelatin, and about *four grammes* if made with oil of theobroma." *U. S.*

The U. S. Pharmacopœia gives no detailed formulæ for suppositories, except in one case, *Suppositoria Glycerini.*

Suppositories are used in medicine (1) for the purpose of obtaining the systemic action of drugs after their absorption, (2) for the local effects of their ingredients. There is an old superstition among the medical profession that systemically acting drugs introduced per rectum have more effect upon the pelvic organs than when given by the mouth, and suppositories of opium, belladonna, etc., are habitually recommended in the treatment of diseases of the bladder and uterus. This view, however, is patently erroneous. The per rectum channel of exhibiting systemically acting drugs may, however, be of service in those cases in which deleterious influence upon the stomach is feared. Speaking in a general way, quantities of about double the dose exhibited by the mouth may be given in the form of suppositories. As a means of obtaining the local action of astringents, anesthetics, or antiseptics, upon the mucous membrane of the rectum suppositories are very valuable.

SUPPOSITORIA ACIDI CARBOLICI. Br.

PHENOL SUPPOSITORIES

(sŭp-pŏs-ĭ-tō'rĭ-ă ăç'ĭ-dī kăr-bŏl'ĭ-cī)

Carbolic Acid Suppositories; Suppositories d'acide Phénique, *Fr.;* Phenol-suppositorien, *G.*

"Phenol, 0.8 gramme; White Beeswax, 0.5 gramme; Oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Dissolve the Phenol in the Oil of Theobroma, previously melted, add the White Beeswax, and pour the melted mixture into suitable moulds; or let the mixture cool and then divide it into twelve equal parts, and press each into a conical or other convenient form for a suppository. Each of these Suppositories contains 0.067 gramme (about 1 grain) of Phenol." *Br.*

These suppositories may be used to obtain the local anesthetic and antiseptic effect of phenol. The wax is needed to offset the tendency to liquefy.

SUPPOSITORIA ACIDI TANNICI. Br.

TANNIC ACID SUPPOSITORIES

(sŭp-pŏs-ĭ-tō'rĭ-ă ăç'ĭ-dī tăn'nĭ-cī)

Suppositories de Tannin, *Fr.;* Tanninsuppositorien, Tannin-Stuhlzäpfchen, *G.*

"Tannic Acid, 2.4 *grammes;* Oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Melt the Oil of Theobroma; triturate the Tannic Acid intimately with a little of the Oil, and add to the remainder; stir well; as the mixture begins to thicken pour it into suitable moulds; or let the mixture cool and then divide it into twelve equal parts, and press each into a conical or other convenient form for a suppository. Each of these Suppositories contains 0.2 gramme (about 3 grains) of Tannic Acid." *Br.*

As it is hardly conceivable that a rectal dose of less than five grains should be wanted for the adult, the U. S. preparation of 1870 was of the latter strength (*i.e.,* five grains). The benzoated lard formerly added by the British authorities with a view of preventing rancidity has been omitted. The remedy is especially applicable to cases of *piles* and *prolapsus of the rectum.*

SUPPOSITORIA BELLADONNÆ. Br.

BELLADONNA SUPPOSITORIES

(sŭp-pŏs-ĭ-tō'rĭ-ă bĕl-lă-dŏn'næ)

Suppositoires de belladone, *Fr.*; Belladonnasuppositorien, *G.*

"Liquid Extract of Belladonna, 1.7 *millilitres;* Oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Evaporate the Liquid Extract of Belladonna to a syrupy consistence; mix with the Oil of Theobroma, previously melted; as the mixture begins to thicken pour it into suitable moulds; or let the mixture cool and then divide it into twelve equal parts, and press each into a conical or other convenient form for a suppository. Each of these Suppositories contains, approximately, 0.001 gramme (about 1/60 grain) of the alkaloids of Belladonna Root." *Br.*

SUPPOSITORIA GLYCERINI. U. S., Br.

SUPPOSITORIES OF GLYCERIN Supp. Glycerin.

(sŭp-pŏs-ĭ-tō'rĭ-ă glĭç-ĕ-rĭ'nī)

Suppositoires de Glycérin, *Fr.*; Glycerinsuppositorien, *G.*

* "Glycerin, *thirty grammes* [or 1 ounce av., 25.5 grains]; Monohydrated Sodium Carbonate, *five-tenths of a gramme* [or 7.7 grains]; Stearic Acid, *two grammes* [or 31 grains]; Water, *five mils* [or 81 minims], to make *ten rectal suppositories.* Dissolve the monohydrated sodium carbonate in the water and add it to the glycerin contained in a suitable vessel placed in a water bath in such a way that the vessel is well down in the boiling water and its contents protected as much as possible from the steam of the bath. Add the stearic acid and heat the mixture for fifteen minutes or until the carbon dioxide ceases to be evolved, and the liquid is clear. Then pour the melted mass into suitable moulds, remove the suppositories when they are completely cold, and preserve them in tightly-stoppered glass vessels in a cool place." *U. S.*

"Gelatin, cut small, 14 *grammes;* Glycerin, 70 *grammes;* Distilled Water, *a sufficient quantity.* Soak the Gelatin in the Distilled Water for five minutes, or until thoroughly softened; drain well, add the Glycerin, dissolve on a water-bath and evaporate until the mixture weighs one hundred grammes. Pour the product into suitable moulds having capacities corresponding to two, four, or eight grammes of the Suppository, or of such other capacities as may be required. Each of these Suppositories contains 70 per cent. by weight of Glycerin." *Br.*

These were official for the first time in the U. S. P. 1890. Glycerin suppositories have come into extensive use, the object being to introduce glycerin into the rectum with a minimum amount of other ingredients. Stearic acid was selected on account of its forming with sodium carbonate the hardest soap attainable, thus permitting the introduction of a suppository containing at least 90 per cent. of glycerin, the water, added to dissolve the monohydrated sodium carbonate, and some of the glycerin being evaporated during the manipulation. This process was perfected by J. P. Remington. (See *Practice of Pharmacy,* 6th ed.) The British method, on account of the use of gelatin, permits the presence of only 70 per cent. of glycerin, the suppository not being firm enough for convenient application, and, in addition, the method of hydrating the gelatin is faulty. (*C. D.*, 1898, 831.) Instead of wrapping the suppositories in tin foil it will be found more satisfactory to insert each one in a small glass tube of the proper size, corked at both ends, or in small individual cylindrical vials. Some protection from the moisture in the air is necessary because of the hygroscopic character of glycerin. (See *P. J.*, 1893, 63; 1895, 182; *Am. Drug.*, 1894, 91; *West. Drug.*, 1894, 141; *A. J. P.*, 1895, 599.)

Uses.—Glycerin suppositories are very much used to produce fecal discharges in *constipation.* They act by locally irritating the mucous membrane of the rectum, and are often satisfactory, though never really purgative. As an occasional remedy they are useful, but their habitual employment is probably injurious to the mucous membrane.

SUPPOSITORIA IODOFORMI. Br.

IODOFORM SUPPOSITORIES

(sŭp-pŏs-ĭ-tō'rĭ-ă ĭ-ŏd-ō-fŏr'mī)

Suppositoires d'Iodoforme, *Fr.*; Jodoformsuppositorien, *G.*

"Iodoform, in powder, 2.4 *grammes;* Oil of Theobroma, *a sufficient quantity* for twelve suppositories each weighing about one gramme. Proceed as directed for Suppositoria Acidi Tannici. Each of these Suppositories contains 0.2 gramme (about 3 grains) of Iodoform." *Br.*

These suppositories are valuable in cases of rectal inflammation and irritation. It is often possible by their use in *dysentery* to avoid the use of opium to a greater or less extent. They are especially serviceable to relieve the pain and itching of *hemorrhoids.*

SUPPOSITORIA MORPHINÆ. Br.

MORPHINE SUPPOSITORIES

(sŭp-pŏs-ĭ-tō'rĭ-ă mör-phī'næ)

Suppositoires de Morphine, Suppositoires morphinés, *Fr.*: Morphinumsuppositorien, Morphin-Stuhlzäpfchen, *G.*

"Morphine Hydrochloride, 0.2 *gramme;* Oil of Theobroma, *a sufficient quantity,* for twelve suppositories each weighing about one gramme. Proceed as directed for Suppositoria Acidi Tannici. Each of these Suppositories contains 0.017 gramme (about ¼ grain) of Morphine Hydrochloride." *Br.*

These may be used to obtain the systemic effects of morphine when, for any reason, it is undesirable to exhibit that drug by mouth.

SUPPOSITORIA PLUMBI COMPOSITA. Br.

COMPOUND LEAD SUPPOSITORIES

(sŭp-pŏs-ĭ-tō'rĭ-ă plŭm'bī cŏm-pŏs'ĭ-tă)

Suppositoires de Plomb composés, Suppositoires de Plomb opiacés, *Fr.*; Zusammengesetzte Bleisuppositorien, *G.*; Stuhlzäpfchen von Opium und Bleizucker, *G.*

"Lead Acetate, in powder, 2.4 *grammes;* Opium, in powder, 0.8 *gramme;* Oil of Theobroma, *a sufficient quantity,* for twelve suppositories each weighing about one gramme. Proceed as directed for Suppositoria Acidi Tannici. Each of these Suppositories contains 0.2 gramme (about 3 grains) of Lead Acetate, and 0.067 gramme (about 1 grain) of Opium." *Br.*

This irrational combination is occasionally used in *diarrhea* or *hemorrhoids.*

SUPRARENALUM SICCUM U. S.

DRIED SUPRARENALS Supraren. Sicc. [Glandulæ Suprarenales Siccæ U. S. VIII, Desiccated Suprarenal Glands]

(sūp-ră-rē-nā'lŭm sĭc'cŭm)

"The suprarenal glands of animals which are used for food by man, cleaned, dried, freed from fat, and powdered, and containing not less than 0.4 per cent. nor more than 0.6 per cent. of epinephrine, the active principle of the suprarenal gland. One part of Dried Suprarenals represents approximately 6 parts of fresh glands, free from fat. If assayed biologically *one gramme* of Dried Suprarenals contains the equivalent of *ten milligrammes* of lævo-methylaminoethanol-catechol." *U. S.*

The suprarenal glands are small organs found in all mammals, situated in the neighborhood of the kidney. When freed of their fat and dried they may be pulverized. This is a "light yellowish-brown, amorphous powder, having a slight, characteristic odor; partially soluble in water. Dried Suprarenals contain not more than 7 per cent. of moisture, and the yield of ash does not exceed 7 per cent.

"**Assay.**—Add 0.005 Gm. of finely powdered manganese dioxide and 10 mils of distilled water to 0.01 Gm. of Dried Suprarenals; thoroughly shake the mixture several times during one hour and filter. Compare the color of the filtrate in a test tube or in any convenient manner, with the color of cobaltous chloride T.S. and diluted gold chloride T.S. (see Reagents, Part III) combined as follows: Mix 1.85 mils of cobaltous chloride T.S. with 0.95 mil of diluted gold chloride T.S. and 7.2 mils of distilled water; the color corresponds to 0.2 per cent. of epinephrine in the filtrate obtained above; 2.95 mils of cobaltous chloride T.S. with 1.25 mils of diluted gold chloride T.S. and 5.8 mils of distilled water corresponds in color to 0.4 per cent. of epinephrine; 4.05 mils of cobaltous chloride T.S. with 1.35 mils of diluted gold chloride T.S. and 4.6 mils of distilled water corresponds in color to 0.6 per cent. of epinephrine; 5.15 mils of cobaltous chloride T.S. with 1.55 mils of diluted gold chloride T.S. and 3.3 mils of distilled water corresponds in color to 0.8 per cent. of epinephrine. The percentages of epinephrine indicated by the above color standards are based upon the maceration of 0.01 Gm. of the Dried Suprarenals in 10 mils of distilled water, as directed above, and filtering. In samples containing more than 0.8 per cent. of epinephrine, 0.005 Gm. of the Dried Suprarenals may be taken, in which case the percentage stated above, as indicated by the color standards, should be doubled. The standard color solutions keep unchanged, if sealed in glass tubes. For a method of assaying Dried Suprarenals, see Biological Assays (Part III)." *U. S.*

It will be noted that the chemical and biological assays differ; the latter requiring the presence of 1 per cent. of active principle, the former only 0.5 per cent. How this discrepancy is to be reconciled surpasses conjecture.

Seidel and Fenger (*U. S. Hygienic Lab. Bull.* No. 100, 1914) have found that the percentage of epinephrine in the suprarenal gland of the beef runs distinctly higher than those of either sheep or swine, varying in the beef glands from 0.4 to 1 per cent., in hogs and sheep from 0.1 to 0.4.

Uses.—An aqueous solution of the dried suprarenals will produce all the effects described under *adrenalin* (see p. 94), but because of its greater convenience the alkaloid is universally preferred. There are one or two conditions, however, in which the whole drug is to be preferred. Foremost among these is that syndrome known as *Addison's disease.* According to S. Solis-Cohen, the administration of the suprarenal gland by the mouth every two or three hours is sufficient to prevent the occurrence of the *asthmatic paroxysm.*

Locally, the suprarenals may be used in solutions of the extract in the proportion of 5 to 25 per cent. As these solutions form excellent culture media for bacteria they are not permanent unless an antiseptic is added.

Dose, three to ten grains (0.2–0.65 Gm.).

SYRUPI.

SYRUPS

(sy-rŭ'pī)

Sirops, *Fr. Cod.*; Sirupi, *P. G.*; Sirupe, *G.*; Sciroppi, *It.*; Jarabe, *Sp.*

Syrups are concentrated solutions of sugar in aqueous fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup;* when made with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup,* and receives its special designation from the substance or substances added.

Medicated syrups are prepared by dissolving sugar in infusions, vinegars, decoctions, expressed juices, fermented liquors, or simple aqueous solutions, or by adding a medicating substance, like a tincture or a fluidextract, to simple syrup. When the active matter of the vegetable is not readily soluble in water, is associated with soluble matter which it is desirable to avoid, or is volatilized or decomposed by a heat of 100° C. (212° F.), it is sometimes ex-

tracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off.

The process of percolation has been applied for the solution of the sugar and is offered as an alternative process in a number of official preparations. This process offers several advantages over the older methods. The amount of labor attending the operation is greatly reduced, no heat is employed so that volatile constituents are not injured, and the finished syrup is filtered and protected from the usual contaminations attending straining, etc. For the mode of properly conducting this process the reader is referred to page 1095.

The quality and quantity of the sugar employed are points of importance. Official granulated sugar should be employed and although the commercial grades are usually of good quality it is possible to secure a sugar of better grade, known as "druggists' dry granular" or "crystal A," which is obtained from the first runnings from the bone-black filters. In this sugar the crystals are large and the syrup is unusually free from yellowish tint, even in a heavy strata. The syrup made from this sugar is often sold as "Rock Candy Syrup."

In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The Pharmacopœial formula calls for 850 Gm. of sugar to make 1000 mils of syrup, the amount of water required being about 465 mils. A somewhat smaller quantity will answer where an acid, such as lemon juice or vinegar, is used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the aqueous fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. The use of concentrated pharmaceutical preparations, such as tinctures and fluidextracts, as the source of medication, has largely replaced other methods. The proper point of concentration for syrups which are prepared on a large scale by boiling is best ascertained by the use of that variety of Baumé's hydrometer called a *saccharometer*. This should stand at 30° in boiling syrup—30.5° in hot weather and at 35° in the syrup when it is cool. Another very accurate, though less ready, method is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup, when boiling, should have a sp. gr. of about 1.261; at 25° C. (77° F.) about 1.313; this is the specific gravity of the official syrup. A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 105° C. (221° F.). This indication is founded on the fact that the boiling point of syrup rises with the increase of its density.

When carefully prepared with the best refined sugar, syrups made by the hot process or by agitation in the cold usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But, as the sugar employed is seldom free from impurities, it may be best, as a rule, to remove the scum as it rises during the heating process, and to strain the syrup while hot through muslin or flannel. The percolation process avoids this necessity. Should syrups at any time lack the due degree of transparency, they may be filtered through paper if a hot water funnel is used, or, when likely to be injured by this treatment, may be clarified by other mechanical means, as mentioned under the head of *Syrupus*. The vicious habit practised not long ago by sugar refiners of "blueing" sugars by the use of ultramarine and other coloring agents cannot be too strongly deprecated, and it is a great benefit to pharmacy that this practice has been discontinued by most sugar refiners. (See *A. J. P.*, 1901, 119.)

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups, when too much boiled, often show a copious white deposit, which is invert sugar produced by the action of the acid upon the sugar. Even at ordinary temperatures, acids slowly convert common sugar into invert sugar, which, being less soluble than the former, is often deposited in the form of crystalline grains. Excessive acidity soon causes a darkening of the syrup, due to caramelization of the sugar. Syrups containing too little sugar are subject to fermentation, in consequence of the presence of yeast cells. Those which contain too much, deposit a portion in the crystalline state, and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups enclosed, while they are still hot, in bottles which are not full are apt to ferment, but if in well filled bottles they will generally keep better. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbon dioxide, and acquire a vinous odor from the presence of alcohol, while their consistence is diminished by the loss of a portion of the sugar, which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases, or goes on more slowly, owing to the preservative influence of the alcohol. Such syrups should never be used for pharmaceutical purposes, as no amount of reboiling can render them fit for use.

The percolation method for preparing syrups has come into general use. For some syrups it is to be preferred to the usual method of heating, and all syrups which contain a volatile

principle, or one likely to be injured by heat, are preferably made by *percolation*. L. Orynski (*D. C.*, March, 1871) first drew attention to the subject. The details of the official method are given below. It was first recommended that a small piece of sponge should be used to close the lower orifice of the percolator, but this has advantageously been replaced by purified cotton. Some experience is necessary in adjusting the cotton, but the proper degree of pressure is soon learned.

To be successful in using the process, care in several particulars must be exercised. (1) The percolator should be cylindrical or semi-cylindrical, and cone-shaped as it nears the lower orifice. (2) The sugar must be coarse, else it will form into a compact mass, which the liquid cannot permeate. (3) The sponge or pledget must be introduced with care. If pressed too tightly in, it will effectually stop the process; if inserted too loosely, the liquid will pass too rapidly, and will, in consequence, be weak and turbid (not properly filtered). See also a practical paper on this subject in *A. J. P.*, Jan., 1881, by G. H. Chas. Klie, and *Bull. Pharm.*, 1902, 1248. For a paper on *Fruit Syrups*, see *West. Drug.*, 1902, 182; *Proc. Penn. Pharm. Assoc.*, 1903, 196.

Syrups may be made (without heat) *rapidly* by putting the ingredients in a churn and agitating briskly.

"Rock Candy Syrup," the evaporated mother liquor left after crystallizing sugar in the form of large crystals, called "rock candy," has come largely into use in America. It varies much in quality as made by various manufacturers, and often contains added glucose. It should never be used indiscriminately or for making the official syrups, and it should always be carefully tested before being used for any purpose. (See analyses by L. F. Kebler, in *A. J. P.*, 1895, 143.)

At best, syrups are apt to change, and various measures have been proposed for their preservation, but the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stoppered, which should be put in the cellar or other cool place. Glycerin is often used to aid in the preservation of syrups; in special cases this may be advantageous, but the solvent properties of glycerin must be remembered, and the finished preparation may possess properties (due to the glycerin) which are not found in syrups made without glycerin, and which may therefore be injurious in prescriptions. (See *West. Drug.*, 1898, 444.)

SYRUPUS. U. S., Br.

SYRUP [Sirup, Simple Syrup]

(sy-rŭ'pŭs)

Syrupus Simplex; Syrupus Sacchari s. Albus; Sirop de Sucre, *Fr. Cod.*; Sirop simple, *Fr.*; Sirupus simplex, *P. G.*; Weisser Sirup, *G.*; Sciroppo semplice, *It.*; Jarabe simple, *Sp.*

* "Sugar, in dry crystalline granules, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Place at the bottom of a glass percolator of suitable size, a layer of purified cotton about one-half inch in thickness, well fitted to the sides of the percolator, and moisten it with a little distilled water. Introduce the sugar into the percolator, make its surface level without shaking or jarring, then carefully pour upon it *four hundred and fifty mils* [or 15 fluidounces, 104 minims] of distilled water and regulate the flow of the liquid, if necessary, so that it passes out in rapid drops. Return the first portion of the percolate until it runs through clear and, when all of the liquid has passed, follow it by distilled water, added in portions, so that all of the sugar may be dissolved and the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly. Syrup may also be prepared in the following manner: Dissolve the sugar with the aid of heat in *four hundred and fifty mils* [or 15 fluidounces, 104 minims] of distilled water, raise the temperature to the boiling point, strain the liquid, and pass enough distilled water through the strainer to make the product, when cold, measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly. Syrup thus prepared has a specific gravity of about 1.313 at 25° C. (77° F.)." *U. S.*

"Refined Sugar, 1000 *grammes;* Distilled Water, sufficient to produce 1500 *grammes*. Heat together until dissolved; add sufficient Distilled Water to produce the required weight. Specific gravity 1.330. *Optical rotation* + 56° to + 58°." *Br.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavor, thick, viscid, nearly colorless, and perfectly transparent. It sometimes requires straining through muslin or it may be filtered through a pledget of cotton or often through paper.

From the observations of Maumené, it appears that a solution of pure cane sugar, when long kept, undergoes a molecular change analogous to that produced by the reaction of weak acids, the saccharine liquid becoming brown when boiled with potassium hydroxide. But, as this phenomenon is exhibited alike by uncrystallizable sugar and by glucose, the experiment does not determine which of those forms of saccharine matter has been produced. (*C. R. A. S.*, xxxix, 914.) Procter observed a similar change in simple syrup which had been kept in his cabinet for six years. (*A. J. P.*, xxvii, 430.) Schaeuffele, having noticed, on one occasion, in the preparation of simple syrup, that the foam exhibited a singular blue color, while a part of the cane sugar was rapidly transformed into the uncrystallizable variety, made investigations as to the cause, and was led to the conclusion that it was the presence of indigo in the loaves of sugar, introduced with the view of giving brilliancy and whiteness, but this conclusion was erroneous, as it is well known that *ultramarine*, and not indigo, was formerly used for this pur-

pose. The presence of a blue coloring matter in sugar was frequently noticed in this country; syrup made from such sugar was not colorless, and in a short time deposited a dark-colored sediment. Colorless "rock candy" forms an excellent source for pure syrup (the broken crystals can be procured cheaply from the manufacturers), and syrup entirely free from impurities is required in making such preparations as syrup of hydriodic acid, syrup of ferrous iodide, etc. Joseph L. Mayer (*J. A. P. A.*, 1916, p. 712) shows that it is unfair to assume that commercial glucose is present as an adulterant of syrup, simply because it contains reducing sugar, for in a series of experiments conducted by him, working with both cold process and hot process syrups, the amount of invert sugar found after standing for one year, ranged from about 8 per cent. to over 40 per cent., depending entirely on the length of time of standing. The grade of granulated sugar known as "crystal A" or as "Druggists' Dry Granular," referred to on page 1094, is used with success in some parts of the country where it can be readily obtained. It is crystallized from the first runnings from the bone-black filters.

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

The U. S. syrup is practically identical with that formerly official, being a trifle stronger, the sp. gr. being given as 1.313 at 25° C. (77° F.). That of the Br. syrup is 1.330 at 15.5° C. (60° F.), probably adapted to the climate of Great Britain, which is not so cold in winter as is ours, at least in the Northern and Middle States.

SYRUPUS ACACIÆ. U. S.

SYRUP OF ACACIA Syr. Acac.

(sy-rŭ'pŭs ą-cā'cĭ-æ)

Syrupus Gummosus; Sirop de Gomme, *Fr. Cod.*; Gummisirup, *G.*; Sciroppo di gomma arabica, *It.*; Jarabe de goma, *Sp.*

* "Acacia, in selected pieces, *one hundred grammes* [or 3 ounces av., 231 grains]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Place the acacia in an enameled or porcelain dish, and add *four hundred and thirty mils* [or 14 fluidounces, 259 minims] of distilled water, and stir occasionally until the acacia is dissolved; then, having added the sugar, place the dish on a water bath and apply heat, gradually increasing the temperature until the water in the water bath boils. Maintain this temperature for fifteen minutes, and stir the syrup from time to time until the sugar is dissolved. Strain the syrup while hot, add sufficient distilled water, recently boiled, to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], and transfer it, while yet hot, into small bottles which have been rinsed with boiling water and heated in an oven at 160° C. (320° F.) for from fifteen to thirty minutes. Close the bottles tightly with rubber stoppers which have been just previously boiled in water for thirty minutes and cap them with paper." *U. S.*

In the 18th edition of this work the process of the U. S. P., 1890, was condemned because of the tendency of the mucilage of acacia to spoil and thus make an unreliable syrup; the U. S. P. (9th Rev.) provides for a practically permanent preparation by the sterilization of the syrup, the containers, and the stoppers. This syrup is useful in the preparation of mixtures, pills, and troches, and is a good demulcent; but, unfortunately, the proportion of the gum to the sugar is too small to meet all the indications calling for the conjoint use of these substances. To avoid fermentation, C. B. Mann commends the use of one fluidounce of glycerin and seven fluidounces of water as the solvent. If the mucilage of acacia be made with chloroform water or a trace of chloroform be added to syrup of acacia, fermentation is measurably retarded, but the present official method is satisfactory for the purpose.

Off. Prep.—Syrupus Morphinæ et Acaciæ, *N. F.*

SYRUPUS ACIDI CITRICI. U. S.

SYRUP OF CITRIC ACID Syr. Acid. Cit.

(sy-rŭ'pŭs ăç'ĭ-dī cĭt'rĭ-cī)

Sirop d'Acide citrique, *Fr. Cod.*; Citronensauresirup, *G.*

* "Citric Acid, *ten grammes* [or 154 grains]; Distilled Water, *ten mils* [or 162 minims]; Tincture of Lemon Peel, *ten mils* [or 162 minims]; Syrup, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the citric acid in the distilled water and add the solution to *nine hundred and fifty mils* [or 32 fluidounces, 59 minims] of syrup, mixing it well. Then add the tincture of lemon peel, shake the mixture, and add enough syrup to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly and preserve it in containers which have been previously washed with boiling water. This preparation must not be dispensed unless it is free from moulds and fermentation products." *U. S.*

This is more uniform in its character, keeps better, and is more readily prepared than lemon syrup, but does not equal it in flavor, if the latter be well made. If long kept it is prone to acquire a musty taste, and to deposit invert sugar copiously, in consequence of the action of the acid on the cane sugar. It is much employed as an agreeable and refrigerant addition to drinks, especially carbonic acid water. Tincture of fresh lemon peel is used in this syrup instead of spirit of lemon which was used in the process of the U. S. P., 1890; spirit of lemon is no longer official and the tincture is preferable as a flavoring agent. Tartaric acid, on account of its greater cheapness, has not infrequently been substituted for the citric acid; but the syrup made with it does not keep so well, and is more apt to be irritating to the stomach.

SYRUPUS ACIDI HYDRIODICI. U. S., Br.

SYRUP OF HYDRIODIC ACID Syr. Acid. Hydriod.

(sy-rŭ'pŭs ăç'ĭ-dī hȳ-drī-ŏd'ĭ-cī)

"*One hundred mils* of Syrup of Hydriodic Acid contains not less than 1.3 Gm. nor more than 1.45 Gm. of HI (127.93)." *U. S.*

Sirop d'Acide Iodhydrique, *Fr.;* Jodwasserstoffsirup, *G.*

* "Diluted Hydriodic Acid, *one hundred and twenty-five mils* [or 4 fluidounces, 109 minims]; Distilled Water, *three hundred mils* [or 10 fluidounces, 69 minims]; Syrup, *five hundred and seventy-five mils* [or 19 fluidounces, 212 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix them." *U. S.*

"Diluted Hydriodic Acid, 100 *grammes;* Distilled Water, 50 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Mix." *Br.*

An unprotected aqueous solution of hydriodic acid is unstable, the iodine being in time always liberated, rendering it irritant and unfit for internal administration, and as it has been proved that syrup protects the acid efficiently, the 1880 Committee of Revision introduced the Syrup of Hydriodic Acid, with the view of furnishing a preparation which should remain, if carefully preserved, for a long time unchanged. The process for this syrup was changed at the U. S., 1890, revision. The "Buchanan" method of producing hydriodic acid by the decomposition of potassium iodide with tartaric acid was employed, the resulting acid potassium tartrate being crystallized out by the use of diluted alcohol and a reduced temperature. Decomposition and the discoloration due to the separation of a trace of iodine were obviated by the use of a small quantity of potassium hypophosphite; this in contact with tartaric acid is decomposed, and the trace of hypophosphorus acid generated is sufficient to protect the solution of hydriodic acid from change, the very small quantity of acid potassium tartrate produced at the same time crystallizing out with the rest of the salt in the diluted alcohol. In the U. S. P. IX the syrup is made by adding diluted hydriodic acid to water and syrup, it having been proved that diluted hydriodic acid could be made so as to be reasonably permanent (see *Acidum Hydriodicum Dilutum,* page 31), but the principal advantage is that the syrup can now be made extemporaneously as needed for prescriptions. Diluted simple syrup has been proved to make a more permanent syrup of hydriodic acid than syrup of official strength. So-called syrup of hydriodic acid is found in the market in which glycerin is the principal diluting constituent. The substitution of glucose for syrup is also practised, the reason being given that the presence of glucose prevents discoloration. (*Proc. A. Ph. A.,* 1897, 221.)

Properties.—Syrup of hydriodic acid is officially described as "a transparent, colorless, or not more than pale straw-colored, syrupy liquid; odorless, and having a sweet and acidulous taste. Specific gravity: about 1.215 at 25° C. (77° F.). Mix 5 mils of Syrup of Hydriodic Acid with a few drops of starch T.S. and add three drops of chlorine water; the liquid acquires a deep blue color. No blue color is produced in the Syrup by starch T.S. alone (*free iodine*).

"**Assay.**—Introduce exactly 25 mils of Syrup of Hydriodic Acid into a flask, dilute it with 100 mils of distilled water, add 40 mils of tenth-normal silver nitrate V.S., agitate the mixture, add 5 mils of diluted nitric acid and 2 mils of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium sulphocyanate V.S. It shows, in each 100 mils, not less than 1.3 Gm. nor more than 1.45 Gm. of HI.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.012793 Gm. of HI." *U. S.*

Uses.—Syrup of hydriodic acid possesses the general therapeutic properties of the alkaline iodides, and is used by various practitioners to obtain alterative effects in *scrofula* and similar disorders. As it contains 1.4 per cent. by weight of absolute hydriodic acid, for practical purposes a teaspoonful may be said to represent about 0.75 of a grain of iodine or a little over 1 grain of potassium iodide. It is evident that the doses in which it is usually administered—from twenty to forty minims (1.3–2.5 mils)—are too small. It should be well diluted at the time of administration, to prevent the possibility of injury to the teeth.

Dose, from one to two fluidrachms (3.75–7.5 mils).

SYRUPUS AROMATICUS. Br.

AROMATIC SYRUP

(sy-rŭ'pŭs ăr-ŏ-măt'ĭ-cŭs)

Sirop Aromatique, *Fr.;* Aromatischer Sirup, *G.*

"Tincture of Orange, 250 *millilitres;* Cinnamon Water, 250 *millilitres;* Syrup, 500 *millilitres.* Mix the Tincture of Orange and Cinnamon Water; shake the mixture with a little *powdered talc;* filter; add the Syrup." *Br.*

This preparation of the Br. Ph., 1898, is practically a simple elixir (see *Elixir Aromaticum,* p. 433); it has been introduced mainly as a vehicle or adjuvant.

SYRUPUS AURANTII. U. S., Br.

SYRUP OF ORANGE Syr. Aurant.

(sy-rŭ'pŭs âu-răn'tĭ-ī)

Syrup of Orange Peel; Sirop d'Ecorce d'Orange amère, *Fr. Cod.;* Sirupus Aurantii Corticis, *P. G.;* Pomeranzenschalensirup, Orangenschalensyrup, *G.;* Sciroppo di arancio amaro, *It.;* Jarabe de corteza de naranja amarga, *Sp.*

* "Tincture of Sweet Orange Peel, *fifty mils* [or 1 fluidounce, 331 minims]; Citric Acid, *five grammes* [or 77 grains]; Purified Talc, *fifteen grammes* [or 231 grains]; Sugar, *eight hundred and twenty grammes* [or 28 ounces av., 405 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Purified Talc in a mortar with the tincture, add gradually

four hundred mils [or 13 fluidounces, 252 minims] of distilled water, filter, and add sufficient distilled water through the filter to obtain *four hundred and fifty mils* [or 15 fluidounces, 104 minims] of filtrate; in this filtrate dissolve the citric acid and sugar by agitation without heat, and add sufficient distilled water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Tincture of Orange, 125 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Mix." *Br.*

The U. S. P. IX process is an improvement over all preceding formulas as the flavor is derived from the tincture of fresh orange peel and the alkaline magnesium carbonate of the U. S. P. VIII, which modified the flavor, has been replaced by inert talc, the latter being used as a distributing and filtering medium. The British preparation, which is a mere mixture of the tincture with syrup, is inferior. The syrup has an agreeable, slightly acid flavor, for which it is alone employed. For a process by E. E. Williams, using powdered pumice to disintegrate the orange peel, see *D. C.,* 1898, 125.

SYRUPUS AURANTII FLORUM. U. S. (Br.)

SYRUP OF ORANGE FLOWERS Syr. Aurant. Flor.

(sy-rŭ'pŭs âu-răn'tĭ-ī flō'rŭm)

Syrupus Aurantii Floris, *Br.;* Sirop de Fleur d'Oranger, *Fr. Cod.;* Pomeranzenblüthensirup, *G.;* Jarabe de azahar, *Sp.*

* "Sugar, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Orange Flower Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the sugar in *four hundred and fifty mils* [or 15 fluidounces, 104 minims] of orange flower water by agitation, without heat, add enough orange flower water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], mix thoroughly and strain. Syrup of orange flowers may also be made in the following manner: Prepare a percolator in the manner described under *Syrupus.* Pour *four hundred and fifty mils* [or 15 fluidounces, 104 minims] of orange flower water upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by orange flower water, until the sugar is all dissolved and the product measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Orange-flower water of commerce, undiluted, 150 *millilitres;* Refined Sugar, 300 *grammes;* Syrup, sufficient to produce 1000 *millilitres.* Mix the orange-flower water with the Refined Sugar in a closed vessel; stand in a moderately warm place, shaking occasionally till dissolved; then add sufficient Syrup to produce the required volume." *Br.*

The second U. S. process, by percolation, will be preferable here. This syrup is used chiefly for flavoring mixtures.

SYRUPUS CALCII LACTOPHOSPHATIS. U. S., Br.

SYRUP OF CALCIUM LACTOPHOSPHATE Syr. Calc. Lactophos.

(sy-rŭ'pŭs căl'cĭ-ī lăc-tŏ-phŏs-phā'tĭs)

Sirop de Lactophosphate (phospholactate) de chaux, *Fr.;* Calciumphospholactatsirup, *G.;* Jarabe de lactofosfato calcico, *Sp.*

* "Precipitated Calcium Carbonate, *twenty-five grammes* [or 386 grains]; Lactic Acid, *sixty mils* [or 2 fluidounces, 14 minims]; Phosphoric Acid, *thirty-six mils* [or 1 fluidounce, 104 minims]; Stronger Orange Flower Water, *fifty mils* [or 1 fluidounce, 331 minims]; Sugar, *six hundred and fifty grammes* [or 22 ounces av., 406 grains]; Glycerin, *fifty mils* [or 1 fluidounce, 331 minims]; Distilled Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. To the lactic acid, mixed with *one hundred mils* [or 3 fluidounces, 183 minims] of distilled water, gradually add the calcium carbonate, stirring until solution is effected. Then add the phosphoric acid, previously diluted with *fifty mils* [or 1 fluidounce, 331 minims] of distilled water, and stir until the precipitate first formed is dissolved. Add *one hundred mils* [or 3 fluidounces, 183 minims] of distilled water, filter the solution, mix the stronger orange flower water with the filtrate, add the glycerin, and dissolve the sugar in the mixed liquids by agitation; then add enough distilled water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] and strain." *U. S.*

"Calcium Lactate, 75 *grammes;* Concentrated Phosphoric Acid, 45 *millilitres;* Orange-flower water of commerce, undiluted, 25 *millilitres;* Refined Sugar, 700 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Mix the Calcium Lactate with four hundred millilitres of the Distilled Water, add the Concentrated Phosphoric Acid and stir until solution is complete, then add the orange-flower water, dissolve the Refined Sugar in the mixture without the aid of heat, and add sufficient Distilled Water to produce the required volume; filter." *Br.*

The U. S. P., 1880, syrup was almost identical with the preparation proposed by William Neergaard. Freshly precipitated calcium phosphate is soluble in lactic acid, and this preparation was such a solution protected from change and rendered more agreeable to the taste by the addition of sugar and orange flower water. As made by this formula it will usually be found to contain a precipitate of a gelatinous character, which gradually forms in the course of a few days or weeks; the means commonly used to prevent this precipitation is the addition of a fluidrachm of hydrochloric acid to a pint of the syrup—hydrochloric acid being a better solvent for calcium phosphate than is lactic acid. The U. S. P. in the last three revisions has prepared calcium lactate by dissolving calcium carbonate in lactic acid and subsequently adding phosphoric acid. Precipita

tion can be avoided by the addition of a trace of hydrochloric acid. The process of percolation to dissolve the sugar may be advantageously substituted here for that of agitation. The syrup is sometimes prepared by dissolving two hundred grains of calcium lactophosphate (which is now furnished by the manufacturing chemists) in a pint of syrup flavored with orange flower water, a fluidrachm of hydrochloric acid being added to prevent precipitation. The British syrup, 1914, is made by dissolving calcium lactate in phosphoric acid. The syrup affords an excellent means of administering calcium phosphate.

Dose, from two to four fluidrachms (7.5–15.0 mils), representing from three to six grains of the lime salt.

Off. Prep.—Elixir Cinchonæ Alkaloidorum, Ferri, et Calcii Lactophosphatis, *N. F.;* Syrupus Calcii Lactophosphatis et Ferri, *N. F.*

SYRUPUS CASCARÆ AROMATICUS. Br.

AROMATIC SYRUP OF CASCARA

(sy-rŭ'pŭs kăs'cą-ræ ăr-ǫ-măt'į-cŭs)

Sirop aromatique de Cascara Sagrada, *Fr.;* Aromatischer Amerikanisch-Faulbaumrindensirup, *G.*

"Liquid Extract of Cascara Sagrada, 400 *millilitres;* Tincture of Orange, 100 *millilitres;* Alcohol (90 per cent.), 50 *millilitres;* Cinnamon Water, 150 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Mix." *Br.*

This was a new syrup in the Br. Pharm., 1898. It forms a convenient means of administering cascara, the alcohol being added to aid its preservation.

Dose, from one-half to two fluidrachms (1.8–7.5 mils).

SYRUPUS CHLORAL. Br.

SYRUP OF CHLORAL

(sy-rŭ'pŭs ċhlō'rąl)

Sirop de Chloral, *Fr. Cod.;* Chloralhydratsirup, *G.;* Jarabe de hidrato de cloral, *Sp.*

"Chloral Hydrate, 200 *grammes;* Distilled Water, 200 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Dissolve the Chloral Hydrate in the Distilled Water; add sufficient Syrup to produce the required volume. 10 millilitres of this Syrup contain 2 grammes of Chloral Hydrate; 1 fluid drachm contains 10.9 grains." *Br.*

Dose, one to two fluidrachms (3.75–7.5 Gm.).

SYRUPUS CODEINÆ PHOSPHATIS. Br.

SYRUP OF CODEINE PHOSPHATE

(sy-rŭ'pŭs cō-dę-ī'næ phŏs-phā'tĭs)

Sirop de Codéine, *Fr. Cod.;* Kodeinsirup, *G.;* Sciroppo di codeina, *It.;* Jarabe de codeina, *Sp.*

"Codeine Phosphate, 5 *grammes;* Distilled Water, 15 *millilitres;* Syrup, sufficient to produce 1000 *millilitres.* Dissolve the Codeine Phosphate in the Distilled Water; add sufficient Syrup to produce the required volume. 10 millilitres of this Syrup contain 0.05 gramme of Codeine Phosphate; 1 fluid drachm contains 0.27 grain." *Br.*

This syrup is intended to furnish a convenient method of using codeine phosphate. A syrup of codeine, made from the sulphate is official in the N. F. (see *Syrupus Codeinæ,* Part III).

Dose, one-half to two fluidrachms (1.8–7.5 mils).

SYRUPUS FERRI IODIDI. U. S., Br.

SYRUP OF FERROUS IODIDE Syr. Ferr. Iod. [Ferri iodidi syrupus P. I.]

(sy-rŭ'pŭs fĕr'rī ī-ŏd'į-dī)

"A syrupy liquid containing not less than 4.75 per cent. nor more than 5.25 per cent. of FeI_2 (309.68). Preserve it in completely filled, tightly-stoppered bottles." *U. S.*

Syrup of Iodide of Iron; Sirop d'Iodure de fer, *Fr. Cod.;* Syrupus Ferri Jodati, *P.G.;* Eisenjodürsirup, *G.;* Sciroppo di protojoduro di ferro, *It.;* Jarabe de yoduro ferroso, *Sp.*

* "Iron, in the form of fine, bright wire, and cut into small pieces, *twelve and five-tenths grammes* [or 193 grains]; Iodine, *forty-one and five-tenths grammes* [or 1 ounce av., 203 grains]; Diluted Hypophosphorous Acid, *twenty mils* [or 325 minims]; Sugar, *five hundred and seventy-five grammes* [or 20 ounces av., 123 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the iron and iodine into a flask of thin glass, having a capacity of about *five hundred mils* [or 1 pint], add to it *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of distilled water. Shake the mixture occasionally, checking the reaction, if necessary, by placing the flask in cold water, and, when the solution has acquired a greenish color, and has lost the odor of iodine, heat it to boiling and add at once *fifty grammes* [or 1 ounce av., 334 grains] of the sugar; when this has dissolved, filter the solution into the remainder of the sugar contained in a porcelain dish. Rinse the flask and iron wire with *one hundred and twenty-five mils* [or 4 fluidounces, 109 minims] of distilled water and pass the washings through the filter into the sugar. Stir the mixture with a glass rod or a porcelain spatula, heating the liquid on a water bath until complete solution is effected, and, having passed the syrup through a clean muslin strainer into a tared bottle, add the diluted hypophosphorous acid, and sufficient distilled water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

"Iron, in wire, 15.0 *grammes;* Iodine, 41.4 *grammes;* Distilled Water, 75.0 *millilitres;* Glucose, 100.0 *grammes;* Syrup, sufficient to produce 1000.0 *grammes.* Add the Iron and the Iodine to fifty millilitres of the Distilled Water

in a flask; shake occasionally, cooling if necessary. When the reaction is completed add the Glucose, heat on a water-bath for five minutes, mix, and while still hot filter into a tared vessel containing part of the Syrup. Rinse the flask and wash the filter-paper with the remaining twenty-five millilitres of the Distilled Water heated to boiling; add sufficient Syrup to produce the required weight." *Br.*

W. G. Toplis (*Proc. Penna. Pharm. Assn.*, 1916, p. 243) substitutes Ferrum Reductum for the card teeth officially directed in this process, with the result that the solution can be effected, ready for filtration, in less than ten minutes, working with the official proportions.

These preparations furnish solutions of ferrous iodide rendered more permanent by sugar. The iodine should be dry, for, if moist, as commercial iodine often is, less ferrous iodide will be formed and the syrup will be proportionally weaker. In both processes a large excess of iron is taken. A moderate excess is useful in preventing the solution of ferrous iodide from undergoing any change from the absorption of oxygen during filtration, before it comes in contact with the sugar. The method adopted in the Pharmacopœia of 1880, of filtering the unprotected solution of ferrous iodide into the sugar contained in an open porcelain dish, and afterward straining the syrup through linen, was directly opposed to the experience of many practical pharmacists, and to the views which had been hitherto held of the action of the air upon the solution of ferrous iodide, and although with care, in skilful hands, oxidation may have been avoided, nothing was gained in time. In the U. S. P. IX process a small quantity of sugar is added to the solution of ferrous iodide before filtering, but the principle change was in the reduction of the strength of the finished syrup to 5 per cent. of ferrous iodide, which is *one half the quantity of ferrous iodide* that was in the former official syrup (10 per cent.). The strength of 5 per cent. is that recommended by the Brussels International Conference for the unification of the formulas for Potent Remedies.

Properties.—It is officially described as "a transparent, pale yellowish-green, syrupy liquid, having a sweet, strongly ferruginous taste and a slightly acid reaction. Specific gravity: about 1.35 at 25° C. (77° F.). Add a few drops of potassium ferricyanide to 5 mils of Syrup of Ferrous Iodide; a blue precipitate is produced. Mix 5 mils of Syrup of Ferrous Iodide with a few drops of starch T.S. and add three drops of chlorine water; the liquid acquires a deep blue color. No blue color is produced in the Syrup by starch T.S. alone (*free iodine*).

" **Assay.**—Dilute about 10 Gm. of Syrup of Ferrous Iodide, accurately weighed, with 30 mils of distilled water, add 50 mils of tenth-normal silver nitrate V.S., and 5 mils of nitric acid and heat on a water bath until the precipitate of silver iodide is yellow. Cool, add 2 mils of ferric ammonium sulphate T.S., and determine the residual silver nitrate by titration with tenth-normal potassium sulphocyanate V.S. It shows not less than 4.75 per cent. nor more than 5.25 per cent. of FeI_2.

" Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.015484 Gm. of FeI_2. Each gramme of Syrup of Ferrous Iodide corresponds to not less than 3.07 mils nor more than 3.4 mils of tenth-normal silver nitrate V.S." *U. S.*

" When 5 grammes of the Syrup are diluted with 20 millilitres of *water,* acidified with *nitric acid* and mixed with 20 millilitres of *N/10 solution of silver nitrate,* not less than 3.5 or more than 4.2 millilitres of *N/10 solution of ammonium thiocyanate* are required to produce a permanent red coloration, *solution of ferric sulphate* being used as indicator, corresponding to not less than 4.9 and not more than 5.1 grammes of ferrous iodide, FeI_2, in 100 grammes of the Syrup. 10 millilitres of this Syrup contain about 0.7 gramme of ferrous iodide; 1 fluid drachm contains 3.75 grains. It is of the strength required by the International Agreement, and is approximately of two-thirds the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

In regard to the former U. S. syrup, E. S. Wayne observed that, when kept for some time, it occasionally deposited invert sugar, into which the cane sugar was converted through the agency of hydriodic acid. According to J. M. Maisch, the solution was decomposed not only by light, but also by the action of atmospheric oxygen in bottles partly filled and frequently opened. The oxidation of the iron and the evolution of the iodine were accelerated by the action of light, when the solution was thus insecurely kept; but when the altered solution was transferred to air-tight bottles completely filled, and exposed to the direct light of the sun, it resumed its transparency, and its original tint was restored, or its color rendered much lighter. After this restoration the solution could not be the same, and it is probably that it contained some ferric iodate. The removal of the apparent defects of a solution of ferrous iodide by the action of sunlight is, therefore, not an admissible expedient, because it changes the nature of the solution. The same may be said of the addition of tartaric or citric acid, which has been proposed for clearing the discolored syrup. Syrup of ferrous iodide is rendered brown by sulphuric acid, and emits violet vapors when heated.

Syrup of ferrous iodide will on long keeping become permanently discolored through the action of hydriodic acid on the sugar, which causes caramelization, an effect frequently observed in syrups containing citric, tartaric, or other acids. This discoloration must not be confounded with that due to the liberation of iodine. J. F. Judge (*A. J. P.*, 1876, p. 159) recommended hypophosphorous acid in small proportions to restore the pale green color, and of all the additions that have been proposed this is unquestionably the least objectionable and the

most effective. (*Y. B. P.*, 1885, p. 484.) Charles Rice preserved syrup of ferrous iodide successfully on the large scale by storing it in vessels having a stopcock at the bottom and pouring a small quantity of pure olive oil upon the surface to protect from oxidation. A. G. Hammer proposed the addition of syrup to a boiling solution of ferrous iodide before filtering from the excess of iron, and attributes the success in preservation to the fact that a portion of the cane sugar is converted into grape sugar which he believes has greater powers in preventing change. (*Pharm.*, 1876, p. 99.) Glycerin has been proposed as a substitute for sugar in this preparation; it answers the same purpose, but it may be doubted whether more effectually. Glucose or solution of grape sugar has been repeatedly recommended as superior to ordinary syrup for use in this preparation; when the glucose is pure, it is superior as a preservative.

When the syrup is concentrated it becomes brown, and when evaporated to dryness forms a mass which may be called *saccharine ferrous iodide,* and which is not entirely soluble again, a little ferric oxide being left. This saccharine iodide, being protected by the sugar it contains, is not liable to the objections which apply to the pure solid salt (see *Ferrous Iodide,* Part II), and may be made into pills. (See *U. S. D.*, 19th edition, page 1225, for *Ferri Iodidum Saccharatum.*)

Notes on examination of market samples and conclusions and recommendations as to methods of preservation, keeping qualities, etc., have been published by the following authors: L. A. Brown, *Proc. Ky. Ph. Assn.*, 1914, 61; W. C. Alpers, *J. A. Ph. A.*, 1914, 420; G. M. Beringer, *J. A. Ph. A.*, 1914, 970.

Uses.—Syrup of ferrous iodide combines the alterative action of iodine with the hematinic action of iron. It is a popular remedy in chronic types of *tuberculosis,* especially in the *scrofula* of children. It has, however, no advantage over an extemporaneous combination of an iodine with ferruginous tonic, and has the drawback that the dose of either ingredient cannot be altered singly.

Dose, for an adult, ten to forty minims (0.6–2.5 mils); for a child of two years, two to eight minims (0.12–0.5 mil).

SYRUPUS FERRI PHOSPHATIS. Br.

SYRUP OF FERROUS PHOSPHATE

(sy-rŭ'pŭs fĕr'rī phŏs-phā'tĭs)

Sirop de Phosphate de Fer, *Fr.*; Eisenphosphatsirup, *G.*

"Iron, in wire, 8.6 *grammes;* Concentrated Phosphoric Acid, 62.5 *millilitres;* Syrup, 700.0 *millilitres;* Distilled Water, sufficient to produce 1000.0 *millilitres.* Dilute the Concentrated Phosphoric Acid with an equal volume of Distilled Water in a small flask; add the Iron and heat very gently until dissolved. Filter into the Syrup, and pass sufficient Distilled Water through the filter to produce the required volume. 10 millilitres of this Syrup contain 0.17 gramme of anhydrous ferrous phosphate; 1 fluid drachm contains 1 grain." *Br.*

The process for this syrup of the Br. Pharmacopœia has been greatly improved. H. W. Jones (*P. J.*, 3d ser., v, 541) proposed a formula in which the phosphate was made directly from metallic iron and phosphoric acid. R. Wright (*P. J.*, 1893, 191) improved the formula, and this method is superior to the cumbersome process of preparing a precipitate of ferric phosphate, and dissolving it in phosphoric acid. The syrup is a solution of ferrous phosphate protected by sugar. The sp. gr. is about 1.270. (Umney.) For its properties and uses, see *Ferri Phosphas,* page 471.

Dose, from one to two fluidrachms (3.75–7.5 mils).

SYRUPUS FERRI PHOSPHATIS CUM QUININA ET STRYCHNINA. Br.

SYRUP OF PHOSPHATE OF IRON WITH QUININE AND STRYCHNINE

(sy-rŭ'pŭs fĕr'rī phŏs-phā'tĭs cŭm quī-nī'nă ĕt strȳch-nī'nă)

Syrupus Ferri, Quininæ et Strychninæ Phosphatum, Syrup of the Phosphates of Iron, Quinine, and Strychnine, *N. F.*; Easton's Syrup; Sirop Tonique d'Easton, *Fr.*; Eisenphosphatsirup mit Chinin und Strychnin, Eastonscher Sirup, *G.*

"Iron, in wire, 8.60 *grammes;* Concentrated Phosphoric Acid, 62.50 *millilitres;* Strychnine, in powder, 0.57 *gramme;* Quinine Sulphate, 14.80 *grammes;* Syrup, 700.00 *millilitres;* Distilled Water, sufficient to produce 1000.00 *millilitres.* Dilute the Concentrated Phosphoric Acid with an equal volume of Distilled Water in a small flask; add the Iron and heat very gently until dissolved; add the solution to the Strychnine and Quinine Sulphate previously triturated with thirty millilitres of the Distilled Water; when solution is complete filter the Syrup, and pass sufficient Distilled Water through the filter to produce the required volume. 10 millilitres of this Syrup contain 0.17 gramme of anhydrous ferrous phosphate, 0.148 gramme of Quinine Sulphate, and 0.057 gramme of Strychnine; 1 fluid drachm contains 1 grain of anhydrous ferrous phosphate, 4/5 grain of Quinine Sulphate, and 1/32 grain of Strychnine." *Br.*

This syrup is not official in the U. S. P. IX. In the U. S. P. VIII it was made by diluting the glycerite with syrup, but as the glycerite did not prove to be a permanent preparation, the syrup could not be depended upon as containing the full proportion of the active ingredients. The British Pharm., 1914, retained the syrup of the previous Pharmacopœia unchanged, and the N. F. IV introduced the formula of the U. S., 1890.

Uses.—This syrup has the medicinal activities of its ingredients, but is a very ineligible preparation, and has not even an agreeable taste to excuse its polypharmacy. It is known

as *Easton's Syrup, Aitkin's Syrup, Syrup of the Three Phosphates*, and *Syrup of Triple Phosphates.*

Dose, one to two fluidrachms (3.75–7.5 mils).

SYRUPUS GLUCOSI. Br.

SYRUP OF GLUCOSE

(sy-rŭ'pŭs glu-cō'sī)

"Glucose, 250 *grammes;* Syrup, 500 *grammes.* Mix, by the aid of gentle heat." *Br.*

Sirop de Glycose, *Fr.;* Glykosesirup, *G.*

This was a new preparation of the Br. Ph., 1898. It may be used as a vehicle for syrups which contain chemical salts liable to discoloration through the action of light, but its principal use is to take the place of *treacle* or molasses so much used in British pharmacy as a pill excipient. (See *Pilulæ,* p. 859.)

SYRUPUS HYPOPHOSPHITUM. U. S.

SYRUP OF HYPOPHOSPHITES Syr. Hypophos.

(sy-rŭ'pŭs hȳ-pŏ-phŏs-phī'tŭm)

Syrupus Calcii Hypophosphitis Compositus; Sirop d'Hypophosphite de Chaux composé, Sirop de Hypophosphites, *Fr.;* Hypophosphitsirup, *G.*

* "Calcium Hypophosphite, *forty-five grammes* [or 1 ounce av., 257 grains]; Potassium Hypophosphite, *fifteen grammes* [or 231 grains]; Sodium Hypophosphite, *fifteen grammes* [or 231 grains]; Diluted Hypophosphorous Acid, *two mils* [or 32 minims]; Glycerin, *fifty mils* [or 1 fluidounce, 331 minims]; Sugar, *six hundred grammes* [or 21 ounces av., 72 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the hypophosphites with *five hundred mils* [or 16 fluidounces, 435 minims] of distilled water, until they are dissolved, add the diluted hypophosphorous acid, filter the liquid and pass enough distilled water through the filter to make the filtrate measure *five hundred and forty mils* [or 18 fluidounces, 125 minims]. To this add the glycerin and sugar, dissolve the latter by agitation without heat, and finally add enough distilled water, through the filter, to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Strain if necessary." *U. S.*

The determination of the total phosphorus content, which is the best that can be done toward estimating the value of this preparation, is the most readily accomplished by a modification of the method of Jewett, proposed by Barnard and McAbee (*J. A. P. A.,* 1914, 1505), which consists in oxidizing 2 Gm. of the sample with nitric acid and subsequently estimating as phosphomolybdate. Examinations of commercial samples revealed the fact that most of them were far below the theoretical phosphorus content for the official syrup.

This syrup is a simple solution of calcium, sodium, and potassium hypophosphites, in water, protected by sugar, and flavored with the tincture of fresh lemon peel. The calcium hypophosphite will usually not entirely dissolve; hence the direction to use hypophosphorous acid to complete the solution. Percolation will no doubt be preferred by many to agitation, for dissolving the sugar. It has been stated that the sulphuretted odor sometimes noticed in this syrup is due to the decomposition of sulphates or sulphites (present as impurities in the salts) by the hypophosphorous acid. (*P. J.,* 1895, 143.) Each fluidrachm of the syrup contains about two and a half grains of calcium hypophosphite, and not quite one grain each of the sodium and potassium salts. This syrup affords an excellent means of administering the hypophosphites.

Dose, from one to three fluidrachms (3.75–11.25 mils).

SYRUPUS IPECACUANHÆ. U. S.

SYRUP OF IPECAC Syr. Ipecac.

(sy-rŭ'pŭs ĭp-ę-căc-ū-ăn'hæ)

Sirop d'Ipécacuanha, *Fr. Cod.;* Sirupus Ipecacuanhae, *P. G.;* Brechwurzelsirup, Ipecacuanhasirup, *G.;* Sciroppo di ipecacuanha, *It.;* Jarabe de ipecacuana, *Sp.*

* "Fluidextract of Ipecac, *seventy mils* [or 2 fluidounces, 176 minims]; Acetic Acid, *ten mils* [or 162 minims]; Glycerin, *one hundred mils* [or 3 fluidounces, 183 minims]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dilute the fluidextract of ipecac with *three hundred mils* [or 10 fluidounces, 69 minims] of water to which the acetic acid has previously been added, and mix them thoroughly by shaking, and set the liquid aside in a cool place for twenty-four hours. Then filter, and pass enough water through the filter to make the filtrate measure *four hundred and fifty mils* [or 15 fluidounces, 104 minims]. To this filtrate add the glycerin, dissolve the sugar in the mixed liquids, and add enough water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly, and strain, if necessary. Syrup of Ipecac may also be made in the following manner: Prepare a percolator in the manner described under *Syrupus.* Mix the filtrate obtained as directed in the preceding formula with the glycerin, pour the mixture upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with water, until the sugar is all dissolved and the product measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

The present U. S. syrup is made in accordance with the suggestions of Laidley of Richmond, Va., who found the syrup, as formerly prepared, to spoil on keeping. (*A. J. P.,* xxvi, 103, and July, 1879.) (See a practical paper on this subject by A. Robbins in *A. J. P.,* Aug., 1879.) The substitution of glycerin for a por-

tion of the syrup in the U. S. process is an improvement, but the addition of the very small quantity of Acetic Acid is of questionable utility. For formulæ in which the drug ipecac is employed, the reader may consult *A. J. P.*, 1870, p. 127; 1871, p. 104; May, 1881.

If strictly official fluidextract of ipecac is used in making this syrup, and the process is carried out in all its details, the syrup will remain transparent; but if commercial fluidextract is used, or if the fluidextract has not been very carefully made, it will be necessary to modify the process somewhat to secure a transparent syrup. This may be effected by allowing the diluted fluidextract in the official process for making this syrup to remain for two or three days in a cool place before filtering, and adding to the sugar.

One fluidounce of this syrup should contain the virtues of about thirty grains of ipecac.

Although this syrup possesses all the virtues of ipecac, it is used almost exclusively as a nauseating expectorant in *acute bronchitis*.

Dose, for an adult, as an expectorant, from fifteen to thirty minims (0.9–1.8 mils); as an emetic, half a fluidounce (15 mils).

SYRUPUS LACTUCARII. U. S.

SYRUP OF LACTUCARIUM Syr. Lactucar.

(sy-rŭ'pŭs lăc-tū-cā'rĭ-ī)

Sirop de Lactucarium, *Fr.*; Lactucariumsirup, *G.*

* "Tincture of Lactucarium, *one hundred mils* [or 3 fluidounces, 183 minims]; Glycerin, *two hundred mils* [or 6 fluidounces, 366 minims]; Citric Acid, *one gramme* [or 15 grains]; Orange Flower Water, *fifty mils* [or 1 fluidounce, 331 minims]; Syrup, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the tincture of lactucarium with the glycerin, add the orange flower water in which the citric acid has been previously dissolved, and filter, if necessary. Finally, add a sufficient quantity of syrup to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

The only disadvantage of this syrup is the slight petroleum-like taste which seems to be inseparable from lactucarium preparations made by extracting the resinous principles with petroleum benzin; the new tincture of lactucarium, notwithstanding all the care that can be given to the purification of the petroleum benzin, will still hold a trace of the benzin-residue flavor, which it communicates to the syrup. The recommendations made by various pharmaceutical writers to add a solution of an alkali to cloudy syrup of lactucarium, in order to make it transparent, are inadmissible, for Aubergier has conclusively shown that alkalies destroy the bitter principles of lactucarium.

Jos. W. England and N. D. Streeter both prefer to make the syrup directly from the lactucarium. For processes, see *A. J. P.*, 1883, pp. 393, 593.

Louis Emanuel presents an interesting contribution on the subject in the *Proc. P. P. A.*, 1912, p. 151, in which all processes as well as the product are criticised.

This syrup for half a century has been largely used on the assumption that it possessed properties similar to those of opium without the habit-forming tendency of the latter, and Aubergier's syrup has been in great vogue in Europe and to a less extent in this country. After the passage of the Food and Drugs Act in 1906, the Aubergier preparations of lactucarium were found to contain a declaration on the label of the presence of morphine. In France it is evident that lactucarium had failed to sustain its reputation, for the French Codex introduced Sirop de Lactucarium Opiacé (1884), which contained alcoholic extract of lactucarium, with the addition of one-half the proportion of extract of opium. This was an official recognition of the feeble character of lactucarium, and inasmuch as many persons used the syrup as a substitute for opium or morphine, the fact remained that thousands were deceived and in many cases the opium habit was established. We are of the opinion that lactucarium and its preparations should no longer receive recognition. The formula for Aubergier's syrup will be found in the *U. S. D.*, 19th edition, page 1230.

Dose, two to three fluidrachms (7.5–11.25 mils).

SYRUPUS LIMONIS. Br.

SYRUP OF LEMON

(sy-rŭ'pŭs lĭ-mō'nĭs)

Syrupus Succus Citri; Sirop de Limon (de Citron), Sirop de suc de Limon (de citron), *Fr.*; Citronensirup, Citronensaftsirup, *G.*; Jarabe de limon, *Sp.*

"Lemon Peel, in thin slices or grated, 20 *grammes;* Alcohol (90 per cent.), *a sufficient quantity;* Lemon Juice, 500 *millilitres;* Refined Sugar, 760 *grammes*. Macerate the Lemon Peel in thirty millilitres of the Alcohol for seven days; press; filter; add sufficient of the Alcohol to produce forty millilitres. In the Lemon Juice, clarified by subsidence or filtration, dissolve the Refined Sugar by the aid of gentle heat; cool; add the forty millilitres of alcoholic liquid; mix." *Br.*

The U. S. P. 1880 syrup of lemon was dropped at the 1890 revision; as it is frequently used, the process is appended.

"Lemon Juice, recently expressed and strained, *forty parts* [or seventeen fluidounces]; Fresh Lemon Peel, *two parts* [or one ounce av.]; Sugar, in coarse powder, *sixty parts* [or twenty-eight ounces av.]; Water *a sufficient quantity*, to make *one hundred parts* [or about two pints]. Heat the Lemon Juice to the boiling point; then add the Lemon Peel, and let the whole stand, closely covered, until cold. Filter, add enough Water through the filter to make the filtrate weigh *forty parts* [or measure seventeen fluidounces], dissolve the Sugar in the filtered liquid

by agitation, without heat, and strain." *U. S.* 1880.

The addition of lemon peel to the preparation is an improvement, but the internal white portion of the peel should be carefully removed before adding to the hot lemon juice, or the finished syrup will have a bitter taste. (See *Limonis Cortex.*) This syrup forms a cooling and grateful addition to beverages in *febrile complaints,* and serves to conceal the taste of saline purgatives in solution.

SYRUPUS PICIS LIQUIDÆ. U. S.

SYRUP OF TAR Syr. Pic. Liq.

(sy-rŭ'pŭs pī'cĭs lĭq'uĭ-dæ)

Syrupus cum aquâ piceâ; Syrupus Piceus; Sirop de Goudron, *Fr. Cod.*; Theersirup, *G.*; Jarabe de brea, *Sp.*

* "Tar, *five grammes* [or 77 grains]; Alcohol, *fifty mils* [or 1 fluidounce, 331 minims]; Magnesium Carbonate, *ten grammes* [or 154 grains]; Sugar, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the tar in the alcohol, add the magnesium carbonate and *fifty grammes* [or 1 ounce av., 334 grains] of sugar, and after thorough trituration add *four hundred and ten mils* [or 13 fluidounces, 415 minims] of water. Stir the mixture occasionally during two hours and then filter it, returning the filtrate to the filter until the liquid is clear. Dissolve the remainder of the sugar in the clear filtrate obtained from the treatment of the tar, and strain the syrup, adding sufficient water through the strainer to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Syrup of Tar may also be made in the following manner: Prepare a percolator in the manner described under *Syrupus.* Pour the clear filtered liquid obtained from the treatment of the tar as directed above upon the remainder of the sugar, return the first portions of the percolate until it runs through clear, and, when all the percolate has passed, follow it with water until the sugar is all dissolved and the product measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

In many sections of our country this syrup has been largely used. The process of the U. S. P. IX is an improvement on the one formerly official; the proportion of tar being reduced from 75 Gm. to 5 Gm. It is similar to the U. S. P. VIII process except that the washing of the tar to remove acid constituents has been omitted because these would not be present in a tar which conforms to the U. S. P. tests. The tar is dissolved in alcohol, magnesium carbonate and a little sugar added, the mixture filtered, and more sugar dissolved with the aid of a gentle heat. This syrup affords an excellent method of administering small quantities of tar in the milder forms of subacute or chronic *bronchitis.*

Dose, from one to two fluidrachms (3.75–7.5 mils).

SYRUPUS PRUNI VIRGINIANÆ. U. S., Br.

SYRUP OF WILD CHERRY Syr. Prun. Virg.

(sy-rŭ'pŭs prū'nī vĭr-gĭn-I-ā'næ)

Syrup of Virginian Prune, *Br.* 1898; Sirop d'Ecorce de Cerisier, *Fr.*; Wildkirschenrindensirup, *G.*

* "Wild Cherry Bark in No. 20 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Glycerin, *fifty mils* [or 1 fluidounce, 331 minims]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the glycerin with *two hundred mils* [or 6 fluidounces, 366 minims] of water, moisten the wild cherry bark with *one hundred mils* [or 3 fluidounces, 183 minims] of this mixture, pack it firmly in a cylindrical percolator and pour the remaining *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of the menstruum upon it. When the glycerin-water menstruum has disappeared from the surface of the drug, add sufficient water to saturate the powder and leave a stratum above it. Close the lower orifice, and, having closely covered the percolator, allow the drug to macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding water as a menstruum until the percolate measures *five hundred mils* [or 16 fluidounces, 436 minims]. Dissolve the sugar in the percolate by agitation without heat, strain and pass enough water through the strainer to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly. Syrup of Wild Cherry may also be made in the following manner: Prepare a percolator in the manner described under *Syrupus.* Pour the percolate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it with water, until the sugar is all dissolved and the product measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly. This Syrup should be stored in non-metallic, tightly-closed containers, in a cool place, as it rapidly loses hydrocyanic acid even under the most favorable conditions." *U. S.*

"Wild Cherry Bark, in No. 20 powder, 150 *grammes;* Refined Sugar, in coarse powder, 750 *grammes;* Glycerin, 65 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres.* Moisten the Wild Cherry Bark with Distilled Water; set aside for twenty-four hours in a closed vessel; pack in a percolator; percolate with Distilled Water until four hundred and fifty millilitres have been collected; dissolve the Refined Sugar in the percolated liquid, without heat; add the Glycerin and sufficient Distilled Water to produce the required volume." *Br.*

The British Pharmacopœia introduced this syrup into the 1898 edition. The process is modelled after the U. S. formula.

The U. S. process affords a handsome syrup

with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Procter and Turnpenny in *A. J. P.*, xiv, 27. The introduction of the glycerin into the receiving bottle instead of mixing it with the menstruum was dropped in the process of the U. S. P., which, in our opinion, is a mistake. The glycerin is not needed in the menstruum to increase the astringency of the syrup but it serves a useful purpose in keeping the infusion from decomposing and precipitating a reddish, insoluble substance in the receiving bottle. This syrup should never be made by adding fluidextract to simple syrup, as the fluidextract is likely to vary greatly in quality, and frequently precipitates when mixed with syrup, the syrup when made by the above process is far superior in flavor. It is largely used as a vehicle for cough mixtures.

Dose, one to four fluidrachms (3.75–15.0 mils).

SYRUPUS RHEI. U. S., Br.

SYRUP OF RHUBARB Syr. Rhei

(sy-rŭ'pŭs rhē'ī)

Sirop de Rhubarbe, *Fr.*; Sirupus Rhei, *P. G.*; Rhabarbersirup, Rhabarbersaft, *G.*

* "Fluidextract of Rhubarb, *one hundred mils* [or 3 fluidounces, 183 minims]; Spirit of Cinnamon, *four mils* [or 65 minims]; Potassium Carbonate, *ten grammes* [or 154 grains]; Water, *fifty mils* [or 1 fluidounce, 331 minims]; Syrup, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the spirit of cinnamon with the fluidextract of rhubarb, and add the potassium carbonate previously dissolved in the water, and gradually add this mixture to enough syrup to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Rhubarb, in No. 20 powder, 70.0 *grammes;* Oil of Coriander, 0.5 *millilitre;* Refined Sugar, 840.0 *grammes;* Alcohol (90 per cent.), 280.0 *millilitres;* Distilled Water, sufficient to produce 1000.0 *millilitres.* Mix two hundred and seventy millilitres of the Alcohol with three times its volume of Distilled Water. Moisten the Rhubarb with seventy millilitres of this diluted alcohol and set aside for twenty-four hours in a closed vessel; pack in a percolator; pass the remainder of the diluted alcohol slowly through the moistened powder; evaporate the percolate to four hundred and seventy-five grammes; filter; dissolve the Refined Sugar in the filtrate by the aid of heat; cool; add the Oil of Coriander dissolved in ten millilitres of the Alcohol; mix, and finally add sufficient Distilled Water to produce the required volume." *Br.*

The Br. process is a troublesome and imperfect method.

The U. S. syrup differs from that official before 1890 in several particulars, and, in our opinion, it is greatly improved; the activity of the rhubarb and the corrigent effects of the cinnamon are both secured without impairing the appearance of the finished syrup, while the simplicity of the manipulation must commend the process to all. In the Br. Pharm. 1914 oil of coriander replaced coriander fruit official in the former pharmacopœia.

The official syrup is a mild cathartic, adapted for use with infants, to which it may be given in the dose of a fluidrachm (3.75 mils).

Dose, for adults, two to three fluidrachms (7.5–11.25 mils).

SYRUPUS RHEI AROMATICUS. U. S.

AROMATIC SYRUP OF RHUBARB Syr. Rhei Arom. [Spiced Syrup of Rhubarb]

(sy-rŭ'pŭs rhē'ī ăr-ǫ-măt'ĭ-cŭs)

Sirop de Rhubarbe aromatique, *Fr.*; Gewürzter Rhabarbersaft, *G.*

* "Aromatic Tincture of Rhubarb, *one hundred and fifty mils* [or 5 fluidounces, 35 minims]; Potassium Carbonate, *one gramme* [or 15 grains]; Syrup, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the potassium carbonate in the tincture and add this to sufficient syrup to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

A small amount of alkali is added here to prevent the syrup from becoming turbid.

The *aromatic syrup of rhubarb* is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel complaints of infants; which are so frequent in our cities during the summer season, and as a remedy for which this preparation, or one analogous to it, has been long in use, under the name of *spiced syrup of rhubarb.* The dose for an infant with *diarrhea* is a fluidrachm (3.75 mils), repeated every two hours until the passages indicate by their color that the medicine has operated. It should be borne in mind that the syrup, as prepared by the present formula, contains one-seventh of diluted alcohol, which, though not injurious in most cases in which this syrup is used, might render it too stimulating in some instances of diarrhea in the very young infant.

Dose, one to three fluidrachms (3.75–11.25 mils).

SYRUPUS RHŒADOS. Br.

SYRUP OF RED POPPY

(sy-rŭ'pŭs rhœ'ą-dŏs)

Sirop de Coquelicot, *Fr. Cod.*; Sirop de Pavot rouge, *Fr.*; Klatschrosensaft, *G.*

"Red-Poppy Petals, 260 *grammes;* Refined Sugar, 720 *grammes;* Alcohol (90 per cent.), 50 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Add the Red-Poppy Petals gradually to four hundred millilitres of Distilled Water kept hot upon a water-bath, stir frequently, and afterwards, the vessel being removed, infuse for twelve hours. Then press out the liquid; strain; add the Refined Sugar,

and dissolve by the aid of heat. When nearly cold, add the Alcohol, and sufficient Distilled Water to produce the required volume." *Br.*

The object of introducing the petals into water heated by a water bath is that they may shrink by being scalded, as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor become too thick and ropy. The fine red color of this syrup is its only recommendation. It is very liable to ferment; according to Enders, this can be obviated by evaporating the recently prepared syrup to dryness, keeping the powdered residue in well-stoppered bottles, and dissolving it, as wanted, in four-fifths of its weight of water.

Dose, as stated in the Br. Pharmacopœia, one-half to one fluidrachm (1.8–3.75 mils).

SYRUPUS ROSÆ. Br.

SYRUP OF ROSE

(sy-rŭ'pŭs rō'sæ)

Syrup of Roses, *Br.;* Syrupus Rosarum Rubrarum; Syrup of Red Rose; Sirop de Rose rouge, *Fr.;* Rosensirup, *G.*

Syrup of Rose was deleted from the U. S. P. IX, but the process was introduced into the National Formulary IV (see Part III).

"Dried Red-Rose Petals, 50 *grammes;* Refined Sugar, *a sufficient quantity;* Distilled Water, boiling, 500 *millilitres.* Infuse the Red-Rose Petals in the Distilled Water for two hours; strain; press; heat the infusion to the boiling point; filter; add to the filtrate twice its weight of Refined Sugar and dissolve by the aid of heat." *Br.*

Syrup of rose is mildly astringent, but is valued most for its fine red color, on account of which it is occasionally added to mixtures. The color is developed by the small amount of diluted sulphuric acid which is added.

Dose, a fluidrachm (3.75 mils).

SYRUPUS SARSAPARILLÆ COMPOSITUS. U. S.

COMPOUND SYRUP OF SARSAPARILLA
Syr. Sarsap. Co.

(sy-rŭ'pŭs săr-sa-pa-rĭl'læ cŏm-pŏz'ĭ-tŭs)

Syrupus Sudorificus; Sirop de Salsepareille composé, *Fr. Cod.;* Sirop sudorifique, *Fr.;* Zusammengesetzter Sarsaparillsirup, *G.;* Jarabe de zarzaparrilla compuesto, *Sp.*

* "Fluidextract of Sarsaparilla, *two hundred mils* [or 6 fluidounces, 366 minims]; Fluidextract of Glycyrrhiza, *fifteen mils* [or 243 minims]; Fluidextract of Senna, *fifteen mils* [or 243 minims]; Oil of Sassafras, *two-tenths of a mil* [or 3 minims]; Oil of Anise, *two-tenths of a mil* [or 3 minims]; Methyl Salicylate, *two-tenths of a mil* [or 3 minims]; Alcohol, *nineteen and four-tenths mils* [or 314 minims]; Syrup, *seven hundred and fifty mils* [or 25 fluidounces, 173 minims]; to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the fluidextracts and add the alcohol, in which the methyl salicylate and the oils have been dissolved. Gradually add this solution to the syrup and mix thoroughly." *U. S.*

An important change was made in this compound syrup in the U. S. P. 1890, through the substitution of fluidextracts and volatile oils for the drugs used in the U. S. P. 1880 process. It was further improved in the U. S. P. VIII by doubling the amount of volatile oils. The present syrup is not perfectly transparent, but the U. S. P., 1890, syrup had the same fault. The simplicity of the present formula is a welcome improvement.

In the original edition of the U. S. Pharmacopœia, published in 1820, a process for a syrup of sarsaparilla was adopted, intended to present the famous French *sirop de cuisinier.* This process has been variously modified from time to time, but the present preparation possesses any possible therapeutic virtues of the original preparation.

Uses.—The *compound syrup of sarsaparilla* is a senseless survival of an ancient superstition. As pointed out elsewhere in this work, it is improbable that sarsaparilla possesses any therapeutic virtue, and even if it did the proportion in the compound syrup is too small to exert any effect upon the system. While the syrup has a pleasant flavor, owing to the licorice and volatile oils it contains, as a vehicle it would be improved by omitting the sarsaparilla and the senna.

Corrosive sublimate, which is often given in connection with this syrup, is said to be completely decomposed by it, being converted into calomel. Samuel Kennedy (*Ph. Rec.,* 1888, p. 201) showed that when corrosive sublimate was dissolved in this syrup precipitation invariably occurred; if an equal amount of sodium chloride was added, precipitation was greatly retarded. Lepage of Gisors, proposes as a substitute potassium iodohydrargyrate, which he has found not to undergo decomposition. (See *Potassio-mercuric Iodide,* Part II.)

Dose, of the syrup, half a fluidounce (15 mils), equivalent to somewhat less than a drachm (3.9 Gm.) of the root, to be taken three or four times a day.

Off. Prep.—Syrupus Bromidorum, *N. F.*

SYRUPUS SCILLÆ. U. S., Br.

SYRUP OF SQUILL. Syr. Scill.

(sy-rŭ'pŭs sçĭl'læ)

Syrupus Aceti Scillæ; Sirop de Scille, *Fr.;* Meerzwiebelsirup, *G.*

* "Vinegar of Squill, *four hundred and fifty mils* [or 15 fluidounces, 104 minims]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the sugar in the vinegar of squill with the aid of a gentle heat, then strain the syrup and, when the liquid is cold,

add enough water, through the strainer, to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Vinegar of Squill, 175 *millilitres;* Refined Sugar, 650 *grammes;* Distilled Water, sufficient to produce 1000 *grammes.* Mix the Vinegar of Squill with an equal volume of Distilled Water. In the mixture dissolve the Refined Sugar by the aid of gentle heat; add sufficient Distilled Water to produce the required weight." *Br.*

The present British formula is almost identical with U. S. IX, and differs from that of 1864 in taking the vinegar already formed, instead of preparing it as the first step of the process. Vinegar of Squill of the Br. Pharm. 1914 is double the strength of that formerly official. The heating should be performed as quickly as possible, to prevent undue loss of acetic acid.

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. It is incompatible with ammonium carbonate, but not with ammonium chloride.

Dose, about a fluidrachm (3.75 mils).

SYRUPUS SCILLÆ COMPOSITUS. U. S.

COMPOUND SYRUP OF SQUILL Syr. Scill. Co. [Hive Syrup]

(sy-rŭ'pŭs sĕ-ĭl'lē kŏm-pŏz'ĭ-tŭs)

Coxe's Hive Syrup; Sirop de Scille composé, *Fr.;* Zusammengesetzter Meerzwiebelsirup, *G.*

* "Fluidextract of Squill, *eighty mils* [or 2 fluidounces, 338 minims]; Fluidextract of Senega, *eighty mils* [or 2 fluidounces, 338 minims]; Antimony and Potassium Tartrate, *two grammes* [or 31 grains]; Distilled Water, *ten mils* [or 162 minims] Syrup, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the antimony and potassium tartrate in the distilled water with the aid of heat, add this solution to *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] of syrup and mix thoroughly. Then gradually add the fluidextracts, previously mixed, and finally, sufficient syrup to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is intended as a substitute for the popular preparation called *Coxe's hive syrup,* from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed in the Pharmacopœia, it invariably fermented from the want of sufficient concentration. This defect was corrected many years ago when sugar was substituted for honey, in consequence of the uncertain consistence and constitution of the latter. The present formula is a decided improvement, fluidextracts of squill and senega being used. Percolation has been found very well adapted for dissolving the sugar and producing a transparent syrup. The present U. S. P. process has the merit of simplicity, but, unfortunately, the fluidextract of squill is never a wholly satisfactory preparation.

The name Coxe's hive syrup, which is meaningless because it is not used in the treatment of *hives,* is said to owe its origin to a period when croup, for which the remedy is often used, was known popularly as "hives."

Compound syrup of squill combines the virtues of senega, squill, and tartar emetic, of the last of which it contains about one grain in a fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given with advantage in mild cases of simple *croup,* also in the latter stages of severe cases when the object is to promote expectoration. The dose of this syrup is, for children, from two to twenty minims (0.12–1.3 mils), according to the age, and it may be repeated in cases of croup every fifteen or twenty minutes until it causes vomiting.

Dose, for adults as an expectorant, from twenty to thirty minims (1.3–1.8 mils).

SYRUPUS SENEGÆ. U. S.

SYRUP OF SENEGA Syr. Seneg.

(sy-rŭ'pŭs sĕn'ē-gæ)

Sirop de Polygala, *Fr.;* Sirupus Senegae, *P. G.;* Senegasirup, *G.*

* "Fluidextract of Senega, *two hundred mils* [or 6 fluidounces, 366 minims]; Syrup, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the fluidextract with sufficient syrup to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The syrup affords a very convenient mode of exhibiting senega in pectoral complaints. Owing to the pectinous principle present in senega, the syrup made directly from the root as in the process of 1870 was always turbid. It has been frequently pointed out that the addition of an alkali renders the syrup transparent, and the 1890 process directed the use of a small quantity of ammonia water, although, if the fluidextract of senega which contains alkali be used as in the U. S. P. IX, this addition is unnecessary. This syrup may be given as a nauseating expectorant.

Dose, one or two fluidrachms (3.75 or 7.5 mils).

SYRUPUS SENNÆ. U. S., Br.

SYRUP OF SENNA Syr. Senn.

(sy-rŭ'pŭs sĕn'næ)

Sirop de Séné, *Fr.;* Sirupus Sennae, *P. G.;* Sennasirup, *G.*

* "Fluidextract of Senna, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]; Oil of Coriander, *five mils* [or 81 minims]; Syrup, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the oil of coriander with the fluidextract of senna and add sufficient syrup to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Senna Leaves, 440.0 *grammes;* Oil of Coriander, 0.2 *millilitre;* Alcohol (90 per cent.), 2.0

millilitres; Refined Sugar, 540.0 *grammes;* Alcohol (20 per cent.), 760.0 *millilitres.* Moisten the Senna Leaves with four hundred and forty millilitres of the Alcohol (20 per cent.); pack tightly in a vessel which can afterwards be closed; set aside for three days; press strongly; reserve the liquid obtained; break up the marc; moisten it with one hundred and sixty millilitres of the Alcohol (20 per cent.); set aside for twenty-four hours; press strongly; add the liquid obtained to the portion previously reserved; break up the marc; mix it with the remainder of the Alcohol (20 per cent.); set aside for three hours; press again; evaporate the resulting liquid until it is reduced to such a volume that when added to the reserved liquid the whole measures four hundred and forty millilitres. Mix the evaporated liquid with the reserved liquid; heat the product in a covered vessel to 82° C. (179.6° F.) for a few minutes; set aside for twenty-four hours; filter, and pass Distilled Water through the filter until the filtrate measures four hundred and forty millilitres; add the Refined Sugar, and dissolve in a covered vessel by the aid of gentle heat; cool; add the Oil of Coriander dissolved in the Alcohol (90 per cent.); mix." *Br.*

The process was improved in the U. S. P. VIII by simply adding the fluidextract and oil of coriander to syrup, and this process has been retained in the Ninth Revision.

Dose, of the U. S. syrup of senna, for an adult, from one to four fluidrachms (3.75–15.0 mils); of the Br. syrup from one to two fluidrachms (3.75–7.5 mils).

SYRUPUS TOLUTANUS. U. S., Br.

SYRUP OF TOLU Syr. Tolu.

(sy-rŭ'pŭs tŏl-ū-tā'nŭs)

Sirop de Baume de Tolu, *Fr. Cod.;* Sirop balsamique, *Fr.;* Tolubalsamsirup, *G.;* Jarabe de balsamo de Tolu, *Sp.*

* "Tincture of Tolu, *fifty mils* [or 1 fluidounce, 331 minims]; Magnesium Carbonate, *ten grammes* [or 154 grains]; Sugar, *eight hundred and twenty grammes* [or 28 ounces av., 405 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Rub the tincture of tolu in a mortar with the magnesium carbonate and *sixty grammes* [or 2 ounces av., 51 grains] of the sugar. Then gradually add *four hundred and thirty mils* [or 14 fluidounces, 259 minims] of water, with constant trituration, and filter. Dissolve the remainder of the sugar in the clear filtrate, with the aid of a gentle heat, strain the syrup while hot, and add sufficient water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Syrup of tolu may also be made in the following manner: Prepare a percolator in the manner described under *Syrupus.* Pour the filtrate obtained as directed in the preceding formula upon the remainder of the sugar, return the first portions of the percolate until it runs through clear, and, when all of the liquid has passed, follow it with water, until all of the sugar is dissolved and the product measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Balsam of Tolu, 25 *grammes;* Refined Sugar, 660 *grammes;* Distilled Water, sufficient to produce 1000 *grammes.* Add four hundred grammes of the Distilled Water, boiling, to the Balsam of Tolu; cover lightly and heat on a water-bath for half an hour, stirring frequently. Remove; add Distilled Water, if necessary, so that the liquid, when cold, measures four hundred millilitres. Filter the solution, add the Refined Sugar, dissolve by the aid of a water-bath, and finally add sufficient Distilled Water to produce the required weight." *Br.*

The U. S., 1890, process for this syrup was more satisfactory than that formerly official. It was practically a return to the U. S., 1870, method (based on Finley's process, substituting precipitated calcium phosphate for magnesium carbonate, and using a freshly made strong tincture for the official tincture of tolu.

The U. S. Pharmacopœia VIII and IX process reintroduced magnesium carbonate with much advantage, and has the further improvement of using the official tincture of tolu instead of making the latter from the balsam by a special process. In the British process the soluble principles of the balsam are extracted by boiling it with water, but with great waste of the material, as the water dissolves but a small portion of the active matter. To obviate this waste, the same portion of balsam is, according to Brande, usually employed in successive operations, and it long continues to impart odor and taste to boiling water. W. H. Hostelley's modification is as follows: For making twenty-five ounces of syrup, take one ounce of balsam of tolu, one pound of granulated sugar, and water which has been previously filtered through animal charcoal, enough to make twenty-five ounces; rub the tolu to a fine powder, aided by some of the sugar, and mix this with the remainder of the granulated sugar; now prepare a percolator by placing a piece of cotton in the neck, pack the powder in it, pour in the filtered water, and receive twenty-five ounces of percolate. (*A. J. P.,* 1887, p. 290.) Syrup of tolu is used chiefly to impart its agreeable flavor to mixtures. If a stronger preparation is desired, tincture of tolu may be added in the desired quantity, directing the bottle to be shaken.

Dose, one to four fluidrachms (3.75–15.0 mils).

SYRUPUS URGINEÆ. Br.

SYRUP OF URGINEA

(sy-rŭ'pŭs ür-gĭ'nē-ą)

"Vinegar of Urginea, 175 *millilitres;* Refined Sugar, 650 *grammes;* Distilled Water, sufficient to produce 1000 *grammes.* Mix the Vinegar of Urginea with an equal volume of Distilled Water. In the mixture dissolve the Refined Sugar by the aid of gentle heat; add sufficient Distilled Water to produce the required weight." *Br.*

This syrup corresponds to the Syrup of Squill of the British Pharmacopœia and is used for the same purpose.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

SYRUPUS ZINGIBERIS. U. S., Br.

SYRUP OF GINGER Syr. Zingib.

(sy-rŭ'pŭs zĭn-gĭb'ẹ-rĭs)

Sirop de Gingembre, *Fr.;* Ingwersirup, *G.*

* "Fluidextract of Ginger, *thirty mils* [or 1 fluidounce, 7 minims]; Alcohol, *twenty mils* [or 325 minims]; Magnesium Carbonate, *ten grammes* [or 154 grains]; Sugar, *eight hundred and twenty grammes* [or 28 ounces av., 405 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the fluidextract of ginger and the alcohol, then triturate the liquid in a mortar with the magnesium carbonate and *sixty grammes* [or 2 ounces av., 51 grains] of the sugar. Then gradually add *four hundred and thirty mils* [or 14 fluidounces, 259 minims] of water, with constant trituration, and filter. Dissolve the remainder of the sugar in the clear filtrate, with the aid of a gentle heat, strain the syrup while hot, and add sufficient water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Syrup of Ginger may also be made in the following manner: Prepare a percolator in the manner described under *Syrupus.* Pour the filtrate obtained as directed in the preceding formula upon the remainder of the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it with water, until all of the sugar is dissolved and the product measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Ginger, in powder, 25 *grammes;* Alcohol (90 per cent.), *a sufficient quantity;* Syrup, sufficient to produce 1000 *millilitres.* Prepare fifty millilitres of a strong tincture of the Ginger by the *process of percolation* with the Alcohol. To this add sufficient of the Syrup to produce the required volume." *Br.*

The U. S. P. process has been improved by the addition of magnesium carbonate as an aid in distributing the resinous fluidextract so as to facilitate its solution in water. It is practically a return to the U. S. 1870 method.

The British syrup, being made by the simple incorporation of the tincture with syrup, has of course all the strength of the ginger, but is inferior to the U. S. preparation in appearance and flavor. The old plan of using water as the menstruum for the drug has been abandoned, as the syrup thus made is encumbered with mucilage and starch, and consequently rendered more liable to decomposition. In order that the preparation may be of the proper strength, it is necessary that the fluidextract should have been made with the best ginger and with the official menstruum. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impact flavor particularly to carbonic acid water.

Dose, one to four fluidrachms (3.75–15.0 mils).

TABELLÆ TRINITRINI. Br.

TRINITRIN TABLETS

(tă-bĕl'læ trī-nī'trĭ-nī)

Tablets of Nitroglycerin.

"Trinitrin Tablets are tablets of chocolate each weighing 0.300 gramme and containing 0.0005 gramme (0.5 milligram) of the trinitroglycerin of commerce. Each of these Tablets contains 0.5 milligram (approximately 1/130 grain) of the trinitroglycerin of commerce." *Br.*

A pill of nitroglycerin, made with althea and confection of rose, is recognized by the N. F. (see Part III). They afford a convenient mode of exhibiting glyceryl nitrate, but because of its volatility are apt to lose their strength on keeping.

Dose, one to two tablets.

TALCUM PURIFICATUM. U. S.

PURIFIED TALC Talc. Purif.

(tăl'cŭm pū-rĭ-fĭ-cā'tŭm)

"A purified, native, hydrous magnesium silicate sometimes containing a small amount of aluminum silicate." *U. S.*

Talcum, *U. S. VIII,* Talc purifié, *Fr.;* Gereinigter Talk, *G.;* Talcum Venetum; Soapstone; Talc, *Fr. Cod.;* French Chalk; Creta Gallica; Talc de Venise, Craie de Briancon, *Fr.;* Talcum, *P. G.;* Talk, Talkstein, Speckstein, *G.*

Talc is a native hydrous magnesium silicate which is found in various parts of the world, especially in France, Italy, and the United States. An especially high quality is obtained in New York, Vermont, Virginia, and North Carolina. The production of talc in the United States amounted, in 1915, to 166,336 tons, and of soapstone to 20,555 tons.

It is frequently associated with ferrous oxide, alumina, and lime. It occurs in irregular masses of a greenish-gray color, having a peculiar wax-like appearance of the surface, and giving when rubbed a greasy sensation to the skin. It is odorless, tasteless, and insoluble in water or in dilute solutions of the acids or alkaline hydroxides. It is largely used in the arts, especially in the manufacture of paper when it is used as a filler. For medicinal purposes it is reduced to a fine powder, and purified by washing with hydrochloric acid. The present pharmacopœia gives no process for its purification. That of the U. S. VIII was as follows:

"Talc, in fine powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Hydrochloric Acid, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims]; Water, *a sufficient quantity.* Mix the powdered Talc with about *twenty-five hundred cubic centimeters* [or 5 pints] of boiling Water, gradually add *fifty*

cubic centimeters [or 1 fluidounce, 331 minims] of the Hydrochloric Acid, and boil the mixture during fifteen minutes, then allow it to stand for fifteen minutes. Decant, and reject the supernatant liquid containing the finer particles of Talc in suspension, and again boil the residue with *twenty-five hundred cubic centimeters* [or 5 pints] of Water, mixed with the remainder of the Hydrochloric Acid, and allow it to stand for fifteen minutes. Again decant, and reject the finer suspended particles, and wash the coarser residue with Water by repeated decantation, until a portion of the wash-water, after filtering and acidifying with nitric acid, fails to become opalescent upon the addition of silver nitrate test solution. Then transfer the magma to a close linen or muslin strainer, allow it to drain, and dry it at 110° C. (230° F.)." *U. S. VIII.*

Purified Talc is intended to replace magnesium carbonate, calcium phosphate, and other absorbent powders used to aid filtration, it having the advantage of insolubility, although its absorbent properties are deficient in comparison with magnesium carbonate. As much of the talc sold commercially has been bolted for use in toilet powders it is too fine for use as a filtering medium; the fine particles passing through the pores of the filter paper. For this reason the U. S. P. directs talc for filtering to be not finer than a No. 100 powder.

An interesting and valuable communication on the subject of filtering media is contributed to the *J. A. Ph. A.*, 1916, p. 506, by W. L. Scoville. In it he gives experimental data of the comparison of paper pulp, talc, infusorial earth and Fuller's earth, in filtering aqueous solutions of alkaloids. He says that of the media experimented with, Fuller's earth is the only one producing any marked change in the filtrate, and that it removes from 22 to 100 per cent. of alkaloidal substances from solution, depending upon the alkaloid and whether the liquid is acid, alkaline, or neutral. The "Mechanism of Filtration" is the title of an article by Hatchek (*J. S. C. I.*, 1908, p. 538), in which the effect of various filtering media is scientifically discussed and diagrammatically illustrated.

Properties.—It is officially described as follows: "Purified Talc is a very fine, white or grayish-white powder, which adheres to the skin, is quite free from grittiness and is slippery to the touch; it is odorless and tasteless. Mix 0.5 Gm. of Purified Talc with about 2 Gm. each of anhydrous sodium and potassium carbonates, heat the mixture in a platinum crucible until fusion is complete, and treat the resulting fused mass with hot distilled water. Then neutralize the liquid with diluted sulphuric acid, add 10 mils more of the diluted acid and evaporate the mixture until white fumes of sulphuric acid anhydride are evolved. Add 20 mils of distilled water, boil the mixture and filter; an insoluble residue of *silica* remains. The addition of ammonia water and ammonium chloride to the filtrate may produce a white gelatinous precipitate of *aluminum hydroxide*, and the filtrate from this mixture on the addition of sodium phosphate T.S. yields a white crystalline precipitate of magnesium ammonium phosphate. Purified Talc, when subjected to ignition at red heat, loses not more than 5 per cent. of its weight. Boil 10 Gm. of Purified Talc with 50 mils of distilled water for one-half hour, adding water from time to time to maintain approximately the original volume. It yields a filtrate which is neutral to litmus, and one-half of this filtrate, when evaporated and dried at 110° C. (230° F.), yields not more than 0.005 Gm. of residue (*soluble substances*). The remaining half of this filtrate, after slightly acidulating with hydrochloric acid, does not yield a blue color upon the addition of potassium ferrocyanide T.S. (*iron*). NOTE.—Purified Talc, when used as a filtering medium, should not be finer than a No. 100 powder." *U. S.*

Uses.—Purified talc is used pharmaceutically (see above) and as a protecting, soothing powder to the skin. When in very fine powder it forms the basis of many of the proprietary toilet and infant powders, and is very valuable as a dusting powder in *intertrigo, prickly heat, pruritus,* and other conditions of dermal irritation.

TAMARINDUS. Br.

TAMARIND

(tăm-ą-rĭn'dŭs)

"Tamarinds are the fruits of Tamarindus indica, *Linn.*, freed from the brittle outer part of the pericarp and preserved with sugar." *Br.* The preserved pulp of the fruit of *Tamarindus indica* Linné (Fam. *Leguminosæ*)." *N. F.*

Fructus Tamarindorum; Tamarinier, *Fr. Cod.;* Tamarin Pulpe brute de Tamarins, *Fr.;* Pulpa Tamarindorum cruda, *P. G.;* Tamarindemnus, Tamarinden, *G.;* Tamarindo, *It.;* Tamarindo (Pulpa de), *Sp.*

The tamarind tree (*Tamarindus indica*) is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-colored bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long by a sixth of an inch broad, and of a dark-green color. The flowers, which are in small lateral racemes, have a yellowish calyx, and yellow petals beautifully variegated with red veins. The fruit is a broad, compressed, reddish ash-colored pod, much curved, from two to six inches long, with numerous brown, flat, quadrangular seeds, contained in loculi formed by a tough membrane. Exterior to this membrane is a light-colored acid pulpy matter, between which and the shell are several somewhat branched tough ligneous strands, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are fragile and easily separated.

The tree appears to be a native of the East and West Indies, Egypt, and Arabia, though believed by some to have been imported into America. Barth, the African traveller, found it abundant in the interior of Africa. De Candolle was doubtful whether the East and West India trees are of the same species. It is stated by writers that the pods of the former are much larger than those of the latter, and have a greater number of seeds, the East India tamarinds containing six or seven, those from the West Indies rarely more than three or four; but this seems not to be correct.

Calcutta appears to be the chief emporium for the tamarinds of the European markets. Tamarinds are also sent from the West Indies and Ecuador to England; when from this source they are preferred. The latter are known as American tamarinds, and are obtained from *T. indica,* var. *occidentalis* Gärtn. They are of a light brown color, less cohesive and possess less acidity than the tamarinds from the Old World. Tamarinds are brought to us chiefly from the West Indies, where they are prepared by placing the pods, previously deprived of their shells, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers. In the East Indies tamarinds are often prepared for market by stripping off the outer shell and pressing the pulpy interiors into a mass; sometimes they are packed as in the West Indies.

Properties.—Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable, sour taste, without any mixture of sweetness. In the United States they are usually met with only in the preserved state, this is a dark-colored adhesive mass, consisting of syrup mixed with the pulp, membrane, strong, somewhat branching fibres or string-like strands, and seeds of the pod, and having a sweet acidulous taste. The brown, flattish, quadrangular seeds, each enclosed in a tough membrane, should be hard, clean, and not swollen, the string-like fibers tough and entire, and the odor without mustiness. Tamarind is officially described as "a reddish-brown, moist, sugary mass, containing strong branched fibres, and brown, shining seeds, each enclosed in a tough membrane. Taste agreeable, subacid. The pulp yields no characteristic *reactions* for copper." *Br.*

"A pulpy mass of a light reddish-brown color, changing with age to a dark brown, containing some branching fibers and numerous reddish-brown, smooth, oblong or quadrangular, compressed seeds, each enclosed in a tough membrane. Odor distinct; taste sweet and agreeably acid." *N. F.*

From the analysis of Vauquelin, it appears that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9.40 parts of citric acid, 1.55 of tartaric acid, 0.45 of malic acid, 3.25 of potassium bitartrate, 4.70 of gum, 6.25 of pectin, 34.35 of parenchymatous matter, and 27.55 of water. K. Müller, after analyzing nine commercial varieties, states that only traces of citric and malic acids are present, but that tartaric acid and acid potassium tartrate are present in considerable amount. Copper may often be detected in preserved tamarinds, derived from the boilers in which they are prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a spatula or other steel implement immersed in the tamarinds.

Uses.—Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful when a laxative action is desirable. It is sometimes prescribed in connection with other mild cathartics. Though frequently given with infusion of senna to cover its taste, it is said to weaken its purgative power, and the same observation has been made of its influence upon the resinous cathartics in general. For a formula for *fluidextract of tamarind,* see *Nat. Drug.,* 1892, 101.

Dose, from a drachm to an ounce (3.9–31 Gm.).

Off. Prep.—Confectio Sennæ, *Br., N. F.*

TARAXACUM. U. S. (Br.)

TARAXACUM Tarax. [Dandelion]

(tą-răx'ą-cŭm)

"The dried rhizome and roots of *Taraxacum officinale* Weber (Fam. *Compositæ*). Preserve the thoroughly dried drug in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.* "Taraxacum Root is the fresh root of Taraxacum officinale, *Wiggers.* Collected in the autumn." *Br.*

Taraxaci Radix, *Br.,* Taraxacum Root; Dandelion Root, Blowball, Milk, Witch, or Yellow Gowan, Lion's-tooth, Cankerwort; Pissenlit, Dent de Lion, *Fr. Cod.;* Radix Taraxaci cum herba, *P. G.;* Löwenzahn, *G.;* Tarassaco, *It.;* Taraxacon, Diente de Leon, *Sp.*

The dandelion is an herbaceous plant, with a perennial fusiform root. The leaves, which spring immediately from the short upright rhizome, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine green color. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-colored flower, which closes in the evening and expands with the returning light of the sun. The involucre is smooth and double, with the outer scales bent downward. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is flat and naked. The pappus is stipulate, and at the period of maturity is disposed in a spherical form, and is so light and feathery as to

be easily borne away by the wind, with the achene attached. Another plant resembling the common dandelion, the achenes of which, however, are narrower and bright red or reddish brown, known as the *red-seeded dandelion*, is the product of *T. erythrospermum*, Andrz., and is supposed by some to be naturalized from Europe.

The common dandelion, *Taraxacum officinale*, grows spontaneously in widely separated parts of the globe. It is abundant in this country, adorning our grass plots and pasture grounds with its bright yellow flowers, which, in moist places, show themselves with the first opening of spring, and continue to appear until near the close of summer. In India the plant is cultivated in various parts of the country, and its root collected for use between the months of September and February. (*P. J.*, Dec. 1871, 523.) All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and are sometimes used as a salad. When older and of their natural color, they are medicinal, but the leaves of the wild plant in various stages of its early growth are used for salads by those who have cultivated a taste for this vegetable. The Pharmacopœias recognize only the root. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness by drying, and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter. The juice of the root is thin and watery in the spring; milky, bitter, and spontaneously coagulable in the latter part of summer and autumn, and sweet and less bitter in the winter when affected by the frost. The months of July, August, and September are, therefore, the proper periods for collecting it.

Henry Barton, of Brighton, England, prepared the juice from the flower-stalks by crushing and pressure, adding 25 per cent. of spirit, and, after allowing it to stand for some weeks in glass bottles, filtering to separate a very small quantity of deposit, and setting aside for use. According to Barton, it remains bright, and retains its characteristic taste. Though not so rich in solid constituents as the juice of the root, yet, having an equal bitterness, it is probably not less efficacious as a medicine, if it be true, as stated by Bentley, that the efficacy of the medicine does not depend solely on the amount of its solid constituents, but principally if not entirely on the bitter principle it contains. Barton stated that the juice is certainly one of the best preparations of taraxacum. (*A. J. P.*, 1872, p. 509.)

Properties.—The official description of Taraxacum follows: "Cylindrical or somewhat flattened, gradually tapering, usually in broken pieces, from 6 to 15 cm. in length and from 5 to 15 mm. in thickness; externally brown or blackish-brown, longitudinally wrinkled, having numerous root and rootlet-scars; crown simple or branched with numerous leaf-bases showing annulate markings; odor slight or inodorous; taste bitter. Under the microscope, transverse sections of the root of Taraxacum show a porous, pale yellow wood from 1 to 4 mm. in diameter, surrounded by a light brown bark from 2 to 6 mm. in thickness, the latter composed of concentric layers of lacticiferous vessels and sieve tissues, alternating with whitish inulin-bearing parenchyma. The rhizome portions show a small pith. The powder is light brown; when examined under the microscope it exhibits parenchyma cells which are large, thin-walled and contain irregular masses of inulin; fragments with yellowish-brown lacticiferous vessels; tracheæ reticulate; intermediate fibers non-lignified, with irregular, simple and oblique pores. Taraxacum yields not more than 10 per cent. of ash." *U. S.* "Fresh root frequently three decimetres or more long, and twelve millimetres or more thick, smooth and yellowish-brown externally, whitish within. Fracture short, the exposed surface showing a small yellow porous wood, surrounded by a thick nearly white cortex exhibiting a variable number of irregular concentric rings, from which a milky juice exudes. Inodorous; taste bitter." *Br.*

Taraxacum should be free from the root of *Cichorium Intybus* Linné, which closely resembles it, but is usually paler, more bitter, and has the milk vessels in radiating lines. The drug consists in part of the rhizome which shows from ten to fifteen fibro-vascular bundles surrounded by the parenchyma-tissue of the pith, the diameter of which in some instances exceeds the thickness of the woody zone several times. In other respects the structure of the rhizome resembles the root, the concentric arrangement of the laticiferous ducts in particular excluding any possibility of mistaking the specimens for chicory, etc. (*Am. Drug.*, 1887, p. 2.) The active properties of taraxacum are yielded to water by boiling, and do not appear to be injured in the process. Dragendorff obtained from the root gathered in October and dried at 100° C. (212° F.) 24 per cent. of *inulin* and some sugar. The root gathered in March from the same place yielded 1.74 per cent. of inulin, 17 of uncrystallizable sugar, and 18.7 of *levulin*. This last-named substance, discovered by Dragendorff, has the same composition as inulin, but dissolves in cold water, and is devoid of any rotatory power. Mannite, which has been found in the infusion of the root, has been demonstrated by Smith, of Edinburgh, not to pre-exist in the root, but to be formed by spontaneous changes consequent on exposure.

A crystallizable principle has been extracted from the juice of the root by Pollex, who has named it *taraxacin*. It is bitter and somewhat acrid, fusible, but not volatile, sparingly soluble in cold water, but very soluble in boiling water, alcohol, and ether. It is obtained by boiling the milky juice in distilled water, filtering the concentrated liquor, and allowing

it to evaporate spontaneously in a warm place. The taraxacin crystallizes, and may be purified by repeated solution and crystallization in alcohol or water. Kromayer (*A. Pharm.* (2), cv, 6) also obtained taraxacin, and, in addition, a second crystalline principle, *taraxacerin*, $C_8H_{16}O$, insoluble in water, but soluble in alcohol. According to Vogel, the intra-cellular substance of the root consists chiefly of pectose, which is the result of a metamorphosis of the substance constituting the membrane of the cells. L. E. Sayre found that the yield of taraxacin varies in roots collected at different seasons. (See *Proc. A. Ph. A.*, 1893, 1894, 1895, 1896, 1897.)

F. B. Power (*C. D.*, 1912, p. 822) contributed the results of some investigations of this drug, in which he states that besides inulin, resin and sugar, no definite substances have previously been isolated. The *taraxacin* of Polex (1839), and the *taraxacerin* of Kromayer (1861), to which was assigned the formula $C_{30}H_{50}O_5$, are both alleged to be definite mixtures. Power found in the air dried English root, an enzyme, essential oil, oily resin, fatty acids, including *melissic*, and *p-hydroxy-phenylacetic acid*, which had never before been isolated from a plant.

The roots of various plants have been largely substituted for dandelion in England and on the Continent by the herb gatherers, and we are informed that fraudulent substitution is not unfrequent, in this country, of the root of *Cichorium Intybus*, or *chicory*. It is rare to find chicory mixed with dandelion, the former being usually boldly substituted for the latter.

Uses.—Taraxacum was formerly supposed to possess cholagogic as well as diuretic powers. It has been used in various conditions accompanied with congested or *torpid liver*. There is, however, no sufficient reason for believing it possesses any therapeutic virtues. The dried root is sometimes mixed, in powder, with ground coffee, the taste of which covers that of the dandelion. It is roasted and powdered and then prepared in the same manner.

Dose, one to three drachms (3.9–11.6 Gm.).

Off. Prep.—Fluidextractum Taraxaci, *U. S.* (*Br.*); Extractum Taraxaci, *U. S., Br.;* Succus Taraxaci, *Br.;* Elixir Gentianæ Glycerinatum, *N. F.;* Elixir Taraxaci Compositum, *N. F.*

TEREBENUM. U. S., Br.

TEREBENE Tereben.

(tĕr-ĕ-bē′nŭm)

"A liquid consisting of dipentene and other hydrocarbons, obtained by the action of concentrated sulphuric acid on oil of turpentine. Preserve it in well-closed containers, protected from light." *U. S.* "Terebene is a mixture of dipentene and other hydrocarbons, obtained by shaking oil of turpentine with successive quantities of sulphuric acid until optically inactive, and then distilling in a current of steam." *Br.*

Térébène, *Fr.;* Tereben, *G.*

This substance is produced by the action of sulphuric acid upon oil of turpentine. The sulphuric acid must be added gradually to the cooled oil of turpentine, in the proportion of one part of acid to twenty parts of oil, and after a day's standing the mixture is heated to boiling. After cooling, the oily layer is removed, freed from acid by calcium carbonate, and rectified. The terebene so obtained boils at 156° C. (312.8° F.), is optically inactive and of rather pleasant odor. Some cymol is always produced at the same time, and by continued action of the acid the terebene is said to be entirely converted into cymol and colophene. Jayne and Chase, however, from a study of a number of samples of commercial terebenes (*A. J. P.*, 1887, p. 65), conclude that the boiling point of the true terebene is much higher, 173° to 180° C. (343.4°–356° F.). They found an inactive camphor, boiling at about 200° C. (392° F.) (probably borneol), to be formed also, and the residue left on rectifying was principally *colophene*.

Properties.—*Terebene* is officially described as "a colorless, thin liquid, having a rather agreeable, thyme-like odor, and an aromatic, somewhat terebinthinate taste. One mil of Terebene dissolves in 3 mils of alcohol at 25° C. (77° F.); slightly soluble in water. On exposure to light and air Terebene gradually becomes resinified, and acquires an acid reaction. Specific gravity: 0.860 to 0.865 at 25° C. (77° F.). It boils between 160° and 172° C. (320° and 341.6° F.). Terebene does not redden blue litmus paper which has been moistened with alcohol. Its optical rotation does not exceed +0.3° in a 100 mm. tube at 25° C. (77° F.) (*unaltered oil of turpentine*). After the determination of the boiling point, transfer the residue remaining in the distilling flask to a dish, by means of ether, and evaporate the liquid on a water bath; any residue remaining does not exceed 1 per cent. of the original weight of Terebene taken (*rosin*)." *U. S.*

"A colorless liquid. Agreeable odor; taste aromatic and terebinthinate. Specific gravity from 0.862 to 0.866. Soluble in 5 parts of *alcohol* (90 per cent.). *Optical rotation* at 15.5° C. (60° F.), +1° to −1°. Distils between 156° and 180° C. (312.8° and 356° F.), leaving only a slight viscous residue (absence of excess of resin). Not more than 15 per cent. distils below 165° C. (329° F.)." *Br.*

Power and Kleber (*Ph. Rund.*, 1894, 18) stated that pinene is not obtained by the action of sulphuric acid on oil of turpentine, that the U. S. P., 1890, boiling points 156° to 160° C. (312.8°–320° F.) should be 170° to 185° C. (338°–365° F.), and that the sp. gr. should be 0.855 instead of 0.862; also that terebene consists mainly of *dipentene* and *terpinene* with some cymol and camphene.

Uses.—Terebene is a valuable stimulant expectorant, first recommended by William Murrell (*B. M. J.*, Dec., 1885), in that form of *chronic bronchitis* often known as *winter cough*. It is very useful not only in cases of chronic bronchitis, but also in the *acute* disease, after the earlier stages have passed by. It probably exerts upon other mucous membranes the same

action that it does upon that of the lungs, and it has been employed with asserted good results in *dyspepsia,* especially in the flatulent intestinal variety, and may be used in chronic or subacute inflammation of the genito-urinary tract. Its action upon the general system has not been investigated, but probably resembles that of oil of turpentine. It may be given in emulsion, or by dropping into half a teaspoonful of sugar. It is also sometimes administered in pastils or lozenges. It has been used by atomization, with asserted good results. Murrell (*B. M. J.,* July 24, 1884) states that terebene is an active antiseptic and germicide, one part in four hundred and fifty being able to keep in check the action of the yeast plant, and one part in five hundred having a very perceptible influence on the development of bacilli and paramœcia.

Dose, two to eight minims (0.12–0.5 mil).

TEREBINTHINA CANADENSIS. Br.

CANADA TURPENTINE

(tĕr-ę-bĭn'thĭ-nạ căn-ạ-dĕn'sĭs)

"Canada Turpentine is the oleo-resin obtained from Abies balsamea, *Mill.*" *Br.*

Canada Balsam, Balsam of Fir; Balsamum Canadense; Baume du Canada, *Fr. Cod.;* Térébenthine du Canada, *Fr.;* Canadischer Terpentin, *G.*

The term *turpentine* is usually applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar volatile oil, called *oil of turpentine.* They are generally procured from different species of pine, fir, or larch, though other trees afford products which are known by the same general title, as, for instance, *Pistacia Terebinthinus* L., which yields the Chian turpentine. Some French writers extend the name of turpentine to other juices consisting of resin and essential oil, without benzoic or cinnamic acid, as copaiba, balm of Gilead, etc. We shall describe particularly, in this place, the turpentines which are either now official or have recently ceased to be so. A brief botanical view of the plants from which they are respectively derived will be in accordance with the plan of this work. It is proper to observe first that the family Coniferæ includes about three hundred and fifty species. These may be divided into two sub-orders, as Engler and Prantl suggest—viz., *Pinoideæ* and *Taxoideæ.* Lindley had previously recommended a similar sub-division, but considered each subgroup as deserving of family rank, and gave them the names Pinaceæ and Taxaceæ, which is commonly followed by the authors of Manuals of Botany. The *Pinoideæ* may be further subdivided into the (A) *Abietineæ,* including Araucaria, Pinus, Cedrus, Larix, Picea, Tsuga, Abies, Sequoia, Taxodium, etc.; and (B) *Cupressineæ,* which include Thuja, Juniperus, etc. The *Taxoideæ* include Ginkgo, Taxus, etc.

The genus Pinus is represented by about seventy species, which are widely distributed throughout the northern hemisphere of both continents. The principal centers of distribution of the species of this genus are in the Western United States (twenty-five species), Eastern United States (thirteen species), and the highlands of Mexico. It is one of the most important genera from an economic standpoint. The following species yield valuable timber: *P. palustris, P. Strobus, P. echinata, P. Lambertiana, P. ponderosa, P. monticola, P. heterophylla, P. sylvestris, P. Laricio, P. nepalensis, P. Thunbergii,* and *P. densiflora.* Turpentine is obtained chiefly from the Eastern American *P. palustris* and *P. heterophylla;* it is also obtained from *P. Pinaster* and *P. halepensis* of the Mediterranean basin, and from the Himalayan *P. Roxburghii.* The edible seeds (*Pine Nuts*) of several species yield important articles of human food, the best being produced by the nut pines of Western North America, by *P. pinea* of the Mediterranean, *P. Cembra* of Europe and Asia, and *P. gerardiana* of Northwestern India. *Pine wool,* a coarse fiber manufactured from the leaves of *P. Laricio, P. sylvestris,* and other European species, is used to stuff mattresses and cushions, and woven with animal wool, is made into hospital and military blankets and into underclothing which are reputed to possess medicinal properties. In the Southern United States carpets are woven from the leaves of *P. palustris.* The bark of several species contains sufficient tannin to make them valuable for tanning leather.

1.—*Pinus palustris* Mill. (*P. australis* Michx. *f.*).—The names by which the tree is known in the Southern States are *long-leaved pine, yellow pine, Southern pine, hard pine, Virginia pine,* and *pitch pine;* but the first is the most appropriate. The leaves occur three in a group, being from ten to fifteen inches long, subtended at the base by a conspicuous scaly sheath from one to one and a half inches long. The leaves are crowded at the ends of the branches. The cones are terminal, conical, and armed with a short recurved spine.

This pine is a very large indigenous tree, growing in dry, sandy soils, from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of its height. The leaves are about a foot in length, of a brilliant green color, and united in bunches at the ends of the branches. This tree furnishes by far the greater proportion of the turpentine, tar, etc., consumed in or exported from the United States. (See *Pix Liquida.*)

2.—*Pinus Tæda* L.—This is the *loblolly* or *old field pine* of the Southern States. "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

It is abundant in Virginia, where it occupies the lands exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide spreading top. The leaves are about six inches long, and of a light green color. It yields turpentine in abundance, but the quantity is less

than that which flows from the preceding species.

3.—*Pinus sylvestris* L. *Scotch Pine, Norway Pine, Scotch Fir.*—Leaves in pairs, rigid; strobiles ovate-conical, of the length of the leaves; scales linear-oblong, the ends much thickened, their exposed parts (apophysis) oblique, rhomboidal, with a transverse ridge and central tubercle.

This tree, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits Scotland and the northern and mountainous parts of Europe. It yields a considerable proportion of the common European turpentine.

4.—*Pinus Pumilio* Haenke (*P. montana* Mill.).—This pine is known in gardens under several names which are given to the forms occurring in the different mountain ranges over which it is spread. Beissner, in his *Handbuch der Nadelholzkunde,* considers *P. Pumilio* Haenke, a synonym of *P. montana* Mill., whereas in the *Index Kewensis* the latter is brought under the former. Most authors agree with De Candolle and Beissner in bringing *P. Pumilio* Haenke, under *P. montana* Mill. The latter is a small tree, with decumbent or knee-like more or less erect branches, which are covered with a dark colored persistent bark. The leaves occur two in a sheath, each of which is from one to two inches long, straight, or scythe-shaped, with obtuse apex; both sides are dull green and slightly glaucous. The cones are ovoid, about one and a half inches long, with a pyramidal protuberance on each scale on the outer or exposed side. It is found in the sub-alpine regions of Central Europe at elevations between 4000 and 8000 feet; also on the Carpathian Mountains at from 4000 to 5500 feet. From its branches by spontaneous exudation or by cutting off their ends, *Hungarian balsam* is obtained. A volatile oil is obtained from its leaves (see *Oleum Pini Pumilionis*).

Pinus Pinaster Solander (*P. maritima* Poir.), which is found in the southern and maritime parts of Europe, yields much of the turpentine, pitch, and tar consumed in France, and is admitted among the official plants in the French Codex. *Pinus Lambertiana* of California, produces by exudation a saccharine matter which has been found to contain a peculiar sweet principle called *pinite.* (*C. R. A. S.,* Sept., 1855.) *Pinus Sabiniana* Dougl., known as *nut-pine* or *digger-pine* (because the nut is largely consumed by the Digger Indians), yields, on being notched, a turpentine whose volatile oil is extensively used in California under the name of *abietene.* The *Pinus rigida,* or *pitch pine* of this country, and probably others besides those mentioned, are sometimes employed in the preparation of tar. *Pinus Teocoty* Cham. et Schlecht., yields a turpentine known as *Mexican* or *Brea turpentine,* which is used in Mexico.

Abies.—The genus Abies is represented by about twenty-three species, which are distributed in the New World from Labrador and the valley of the Athabasca River to the mountains of North Carolina and from the mountains of Alaska to the highlands of Guatemala, and in the Old World from Siberia and the mountains of Central Europe to Southern Japan, the Himalayas, Asia Minor, and the mountains of Northern Africa. The species of this genus yield soft, perishable woods and balsamic exudations, which are employed in medicine and the arts.

Abies balsamea (L.) Mill., (*A. balsamifera* Michaux).—"Leaves solitary, flat, emarginate or entire, glaucous beneath, somewhat pectinate, sub-erect above, recurved spreading; cones cylindrical, erect; bracts abbreviate, obovate, conspicuously mucronate, sub-serrulate."

This is the *American silver fir,* or *balm of Gilead tree,* inhabiting Canada, Nova Scotia, Maine, and the mountainous regions farther south. It is an elegant tree, seldom rising more than forty feet, with a tapering trunk, and numerous branches, which diminish in length in proportion to their height and form an almost perfect cone. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish color, and covered with a resinous exudation, which gives them a glossy, rich, and beautiful appearance. It is from this tree that the *Canada balsam* is obtained.

Several other species of Abies are important. The *A. Picea* Lindl. (*Abies pectinata* of De Candolle, *Pinus picea* of Linnæus), or *European silver fir,* growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the *Strassburg turpentine* (*Térébenthine d'Alsace* or *des Vosges*), which is much used in some parts of Europe. By the distillation of its cones with water it also affords a variety of oil of turpentine called in France *essence de templine.* By boiling the young branches of the allied *Picea Mariana* (Mill.), B. S. P. (*Pinus nigra* Link.), or *black* or *bog spruce* of this country, and evaporating the decoction, the *essence of spruce* is prepared. It is a thick, molasses-like liquid, with a bitterish, acidulous, astringent taste, and is used for making *spruce beer.* (See *U. S. D.,* 19th edition, page 1244.)

Abies Fraseri, Lindley.—This species, commonly called *double fir,* occurs at high elevations in the mountains of Tennessee and North Carolina. The tree is noted for its hardiness, and is used for ornamental purposes. It is also said to have been used to furnish a balsam of fir similar to that obtained from *A. balsamea,* but the data concerning this are obscure.

Russian White Pitch, "belji var," "Sos nowaja Smold," which probably derived from the Siberian Fir, *Abies Pichta* Forb. (*Picea obovata* Ledeb.), contains, according to A. Tschirch, two free resin acids, the amorphous, *beljiabiennic acid,* $C_{13}H_{20}O_2$, and the crystalline, *belpiabietinic acid* besides *belpiresene,* $C_{13}H_{36}O$ and an essential oil. (*A. Pharm.,* Nov., 1902.)

Larix.—The genus Larix has eight recognized species, which are now widely distributed over

the sub-arctic and mountainous regions of the northern hemisphere, ranging from the Arctic Circle to the mountains of Pennsylvania in the New World and to latitude 30° in the Old World. The species produce hard, durable, valuable timber; turpentine, which is sometimes used in medicine; tar; bark rich in tannin; and a peculiar manna-like substance.

Larix decidua Mill. (*Larix europæa* De Cand.).—"Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bracts panduriform." The *European larch* is a large tree inhabiting the mountains of Siberia, Switzerland, Germany, and the east of France. It yields the *Venice turpentine* of commerce, and a peculiar sweetish substance called in France *Briançon manna,* which exudes spontaneously and concretes upon its bark. When the larch forests of Russia take fire, a juice exudes from the trunk during their combustion, which concretes and is called *Orenburg gum.* It is wholly soluble in water.

Coniferin is a term which has been given to a principle discovered by Hartig in the cambium of several of the Coniferæ. The species in which it has been found are *Pinus Strobus* and *P. Cembra, Picea Abies* and *A. pectinata,* and *Larix Europæa,* and it probably exists in many others. It is obtained by removing the outer bark, scraping the cambium from the surface of the wood, subjecting this to pressure, boiling the viscid juice to coagulate the albuminous substances, filtering, and evaporating the filtered liquid to one-fifth of its volume. The coniferin is deposited in crystals. The mother-water is very sweet, and contains a saccharine substance closely allied to cane sugar. The crystals are purified by dissolving them in water, decolorizing by animal charcoal, and finally crystallizing from weak alcohol. Coniferin was chemically examined by M. W. Kubel, and later by Tiemann and Haarmann, who proved that it is a glucoside and as crystallized from the juice has the composition $C_{16}H_{22}O_8 + 2H_2O$. When treated with dilute acids or ferments it is decomposed as follows: $C_{16}H_{22}O_8 + H_2O = C_6H_{12}O_6 + C_{10}H_{12}O_3$. When this latter compound is oxidized (or coniferin itself) by potassium dichromate and sulphuric acid, *vanillin* is obtained, $C_6H_3(OH)\begin{cases}OCH_3\\CHO\end{cases}$. Vanillin has been thus made commercially, but is now made preferably from the eugenol of oil of cloves or from benzoin.

In Japan, the exudation from the *Pinus densiflora* Sieb. et Zucc., and that from the *Pinus Thunbergii* Parl. are used under the respective names of *akamatsu* and *kuromatsu.* They are said to contain about 18 per cent. of oil and 81 per cent. of resin. The distilled oil is bright and colorless, having an odor somewhat different from that of the European oil of turpentine. It boils at from 155° to 156° C. (311°–312.8° F.), and has a specific gravity of a little under 0.87. Its index of polarization is from 55° to 61° (dextrogyrate). The resin cannot be distinguished from the European. A turpentine closely resembling the French oil is produced in Burmah from the *Pinus Khasya* Royle, and *Pinus Merkusii* Jungh. et De Vries. (See *P. J.,* lvi, 1896, 370.)

Pistacia.—See *Mastiche.*

Pistacia Terebinthus L. is a small tree of the family Anacardiaceæ, with numerous spreading branches, bearing alternate, pinnate leaves, which consist of three or four pairs of ovate-lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are dicœcious, small, and in branching racemes. It is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the *Chian turpentine* obtained from the tree. A gall produced upon this plant by the puncture of an insect has been used in Eastern Europe in pectoral affections.

We shall treat of the several varieties of turpentine under distinct heads.

1. White Turpentine.

Terebinthina, *N. F. IV;* **Thus Americanum,** *Br.;* **Common Frankincense; Térébenthine de Boston,** *Fr.;* **Terebinthina communis; Térébenthine de Bordeaux ou Térébenthine commune,** *Fr. Cod.;* **Terebinthina,** *P.G.;* **Terpentin, Gemeiner Terpentin,** *G.;* **Trementina comune,** *It.;* **Trementina de pina,** *Sp.*

"A concrete oleoresin obtained from *Pinus palustris* Miller, and from other species of *Pinus* (Fam. *Pinaceæ*)." *N. F. IV.*

Turpentine, or as it is more frequently called, white turpentine, was deleted from the U. S. VIII and the Br. Pharm., 1914. It was introduced in the N. F. IV as an ingredient in *compound rosin cerate,* or Deshler's salve, which was official in the U. S. VIII.

This variety of turpentine is derived chiefly from the *Pinus Palustris* and the *P. Tæda.* It occurs in the sap wood and is obtained by making incisions through the bark and wood and collecting the exudation in cavities or boxes made lower down on the trunk, from which it is dipped into barrels or other receptacles. It gradually thickens and ultimately acquires a soft solid consistence. White turpentine as found in commerce "occurs in yellowish, opaque masses, lighter internally, sticky and more or less glossy, brittle in the cold. Odor and taste characteristic. It is freely soluble in alcohol, ether, chloroform, or glacial acetic acid. Its alcoholic solution is acid to litmus." *N. F.* The following test is of value in testing the purity of turpentine:

"Dissolve about 1 Gm. of Turpentine, accurately weighed, in 25 mils of alcohol and collect the insoluble residue, if any, on a filter which has been dried at 100° C. (212° F.) and weighed. Then wash the residue and filter with about 25 mils of alcohol and dry at 100° C. (212° F.). The weight of the residue does not exceed 2 per cent. (*mechanical impurities*)." *N. F.*

In former times, large quantities were collected in New England, but the turpentine trees

of that section have long been entirely exhausted, and our commerce has been until recently almost exclusively supplied from North Carolina and the southeastern parts of Virginia. Latterly attention was turned to the collection of this valuable product of Georgia and Florida, and now an abundant supply is derived from the vast pine forests which occupy the southern portion of our country bordering on the Gulf of Mexico.

During the winter, deep notches or excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground, and for about three feet above these so-called "boxes" the tree is deprived of its bark and some of the wood scraped off. Into these the turpentine or "crude" begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumn, the tree being scraped every eight or ten days to prevent clogging. The liquid is removed from the "boxes" as they fill, and transferred into casks, where, if left, it gradually thickens, and ultimately acquires a soft solid consistence, but most of it is separated at once by distillation into the rosin and the volatile oil of turpentine.

When a tree is boxed, it is weakened and falls easily before the wind. To obviate the former destructive method, Herty has devised "the cup and gutter system." (See *Bulletin No. 40, Bureau of Forestry.*) By this method a small incision is made through the bark and a strip of galvanized iron is inserted. The turpentine flows along this strip and is caught in an earthenware receptacle much resembling a medium-sized flower pot inserted upon the tree. While this method increases the yield of turpentine, it has not been generally adopted. Large quantities of turpentine are prepared directly from the wood of the trees which have been destroyed by the older or box method of collecting the oleoresin. "Wood" turpentine is not recognized as equivalent to "turpentine" by the Pure Food and Drugs Act, and must be labelled as "Wood Turpentine." The latter has a peculiar odor and is not used in medicine but is widely used in the arts.

White turpentine, as found in commerce, is yellowish white, of a peculiar somewhat aromatic odor, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence varying with the temperature. In the middle of summer it is almost semi-fluid and very adhesive; though brittle in the winter it is often so firm and hard as to be incapable of being made into pills without heat. "In yellowish, opaque masses, brittle in the cold; lighter internally, sticky and more or less glossy; odor and taste terebinthinate. The alcoholic solution of Turpentine has an acid reaction." *U. S. VIII.*

Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about 17 per cent. of volatile oil. (See *Oleum Terebinthinæ.*) It is likely to contain small pieces of bark, wood, or other impurity. Tschirch and Koritschoner found the following constituents in white turpentine: *palabiennic acid*, $C_{13}H_{20}O_2$, 5 per cent.; *palabietinic acid*, $C_{20}H_{30}O_2$, which is crystalline, 6 to 7 per cent.; *α-* and *β-palabietinolic acids*, together 53 to 57 per cent. Both the latter are amorphous and are separated by the differing solubility of their lead salts. All the acids are soluble in sodium hydroxide solution. The portion of the resin insoluble in NaOH solution consists of essential oil, 20 to 22 per cent., and *paloresene*, 10 per cent., with traces of a bitter principle. The essential oil has a characteristic turpentine-like odor. The sp. gr. is 0.864. (See *Oleum Terebinthinæ.*) It is dextrogyrate, while the resin itself and palabietinic acid are lævogyrate. The authors have furthermore examined *Russian white pitch*, a product known as "belji var," and probably derived from the Siberian fir. (*A. Pharm.*, Nov., 1902.)

2. Common European Turpentine.

Térébenthine de Bordeaux, *Fr. Cod.*; Térébenthine commune, *Fr.*; Gemeiner Terpentin, *G.*; Trementina comune, *It.*; Trementina comun, *Sp.*

This is the *Terebinthina vulgaris* of the old London Pharmacopœia. It is furnished by several species of pine, but chiefly by *P. sylvestris* L. and *P. Pinaster* Soland. For details as to the varieties of European turpentine and the methods of procuring them, consult *A. J. P.*, 1878, 69, 479; *Proc. A. Ph. A.*, xxiv, 203; *P. J.*, viii, 283; x, 447. From the latter tree it is obtained largely in the maritime districts of the southwest of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce *Bordeaux turpentine.* It is procured by making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out, in small troughs, or in holes dug at the foot of the tree. It is purified by heating, and filtering it through straw, or by exposing it to the sun in a barrel, through holes in the bottom of which the melted turpentine escapes. Thus prepared, it is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like that of thickened honey. As found in European commerce, it often consists wholly of this latter portion. It speedily hardens on exposure in thin layers to the air. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two parts of the turpentine. (*J. P. C.*, xxv, 499.) Tschirch and Bruening (*A. Pharm.*, 1900, ccxxxvii, 630) find this oleoresin to have the following composition: 6 to 7 per cent. of *pimarinic acid*, $C_{14}H_{22}O_2$; 8 to 10 per cent. of *pimaric acid*, $C_{20}H_{30}O_2$; 48 to 50 per cent. of *alpha- and beta-pimarobic acids*, $C_{18}H_{26}O_2$; 5 to 6 per cent. of *bordoresin*, together with traces of *succinic acid.* The acid resins are soluble in sodium hydroxide solution, the pimarinic acid being separable from the other two by its property of forming with ammonium carbonate a water-soluble double salt. The volatile oil consists of two fractions, the

larger fraction, amounting to about 85 per cent. of the whole, distilling easily. It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and rosin. We do not import it into this country. The substance which the French call *galipot*, or *barras*, is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. (Thénard.) This, when purified by melting with water and straining, takes the name of *yellow* or *white pitch*, or *Burgundy pitch*. When turpentine, whether the European or the American, has been deprived of its oil by distillation, the resin which remains is called *rosin*, and sometimes *colophony*, from the Ionian city of Colophon, where it was formerly prepared. It is the official rosin (*resina*), and is sometimes called yellow rosin (*resina flava*). White rosin (*resina alba*) is prepared by incorporating this, while in fusion, with a certain proportion of water. (See *Resina*.) Tar (*pix liquida*) is the product extracted from the wood by slow combustion and chemically altered by heat. Common pitch (*pix nigra*, or *resina nigra*) is the solid residue left after the evaporation by boiling of the liquid parts of tar.

3. Canada Turpentine.

Baume du Canada, *Fr. Cod.*; Canadischer Balsam, Canadischer Terpentin, *G.*; Trementina del Canada, *It.*

Terebinthina Canadensis, U. S., Br., is collected in Canada and the State of Maine from the *Abies balsamea*, by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. "Pale yellow or greenish-yellow, transparent, viscous. Agreeable terebinthinate odor; taste feebly bitter and acrid. Dries very slowly to a transparent varnish when exposed to the air. Solidifies when mixed with about one-sixth of its weight of *heavy magnesia* moistened with a little *water*." *Br.*

"It is completely soluble in ether, chloroform, or benzene." *U. S. VIII.*

For a paper on its miscibility in alcohol, by J. E. Morrison, see *Proc. A. Ph. A.*, 1894, 309. By time and exposure it becomes thicker and more yellow, and finally solid. It is usually brought into market in bottles under the name of *Canada balsam* or *balsam of fir*. Under the microscope the hard balsam is found to be entirely free from any granular or crystalline structure. In Europe it is sometimes called *balm of Gilead*, from its supposed resemblance to that celebrated medicine. The term *balsam*, as at present understood, is improperly applied to it, as it contains no benzoic or cinnamic acid, and is in fact a true turpentine, consisting chiefly of resin and volatile oil. Bonastre obtained from 100 parts of Canada turpentine 18.6 parts of volatile oil, 40.0 of resin easily dissolved by alcohol, 33.4 of sub-resin of difficult solubility in that fluid, 4.0 of caoutchouc similar to sub-resin, and 4.9 of bitter extractive and salts, besides traces of acetic acid. Flückiger found in 100 parts 24 parts of an essential oil, $C_{10}H_{16}$, with a very small proportion of an oxygenated oil, 60 parts of a resin soluble in boiling alcohol, and 16 parts of a resin soluble only in ether. (*Pharmacographia*, 2d ed., 614.) Emmerich obtained by fractional distillation of the oil, *bornyl* or *terpinyl acetate*, *pinene*, and a fragrant liquid resembling oil of lemon. (*A. J. P.*, 1895, 135. See also a paper by Hunkel, *A. J. P.*, 1895, 9.) The chief distinction between it and *Strassburg turpentine*, which is sometimes sold for it in commerce, is in the odor.

According to Tschirch, Wiegel and Bruening, Canada turpentine contains about 63 per cent. of acid resins, from 23 to 24 per cent. of volatile oil, and from 11 to 12 per cent. of indifferent resin. The acid portion consists of four acids, of which one—*canadinic acid*, $C_{19}H_{34}O_2$—obtained by treating the oleoresin with ammonium carbonate, with which it combines; a small amount of crystalline *canadolic acid*, $C_{19}H_{28}O_2$, and two amorphous isomeric acids—α- and β-*canadinolic acids*, $C_{19}H_{30}O_2$—which constitute the main portion of the acid resins. The indifferent resin has the formula $C_{21}H_{40}O$. The greater part of the volatile oil boils between 160° and 167° C. (320° and 332.6° F.). (*A. Pharm.*, 1900, Aug. and Sept., 401, 411 and 487.)

Abies Menziesii Lind.—From this a *Balsam of Fir* of the Pacific Slope, has been obtained; it is a turpentine similar to Canada balsam and is extensively sold under the names *Oregon Balsam* or Oregon Balsam of Fir. Roberts and Becker (*Proc. P. P. A.*, 1913, p. 328) state that Canada balsam is thicker than Oregon balsam, dries to a solid, transparent film, while Oregon balsam remains sticky, has a lower acid value than Oregon balsam, and solidifies when mixed with 20 per cent. of magnesium oxide, which Oregon balsam does not.

4. Venice Turpentine.

Terebinthina Laricis, *N. F. IV*; Larch Turpentine, Térébenthine de Venise, *Fr. Cod.*; Térébenthine de Mélèze, *Fr.*; Venetianischer Terpentin, *G.*; Trementina di Venezia, *It.*; Trementina de alerce, Trementina de Venecia, *Sp.*

"A viscid oleoresin obtained from *Larix europœa* De Candolle (Fam. *Pinaceæ*)." *N. F.*

"*Venice turpentine* is a nearly transparent, yellowish or yellowish-green, thick liquid, heavier than water, and having a distinctive odor and a bitter characteristic taste. Completely soluble in alcohol, glacial acetic acid, acetone, or chloroform. Almost entirely soluble in petroleum benzin with the separation of a light flocculent deposit. One part of Venice turpentine dissolves completely and forms a clear solution in 3 parts of 80 per cent. alcohol. It may possess a slight, greenish fluorescence when viewed by reflected light but exhibits no violet or purple fluorescence (*rosin oil*). Dissolve 5 Gm. of Venice turpentine in 25 mils of alcohol, add a few drops of phenolphthalein T.S. and render the solution slightly alkaline by the addition of a 10 per cent. solution of

potassium hydroxide. The resulting solution is clear and transparent and no separation of oily drops occurs (*rosin oil*). Its acid number is not more than 80 when determined as directed in the U. S. Pharmacopœia IX." *N. F.*

This turpentine was named from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and in the French province of Dauphiny, from the *Larix decidua* (*L. europæa*), which grows abundantly upon the Alps and the Jura Mountains. The peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice turpentine is a viscid liquid, the consistence of honey, flowing with difficulty, cloudy or imperfectly transparent, yellowish or slightly greenish, of a strong not disagreeable odor, and a warm bitterish, and acrid taste. It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. (Guibourt, *J. P. C.*, xxv, 500.) H. Beckurts and W. Brueche found the specific gravity at 15° C. (59° F.) from 1.060 to 1.190; acid number from 76 to 101 (Kremel found from 68 to 70.3); ester number from nothing to 6; saponification number from 81 to 101, and the iodine number from 137 to 149. (*A. Pharm.*, 1892, ccxxx, 83.) It yields on an average 15 per cent. of essential oil, of the composition $C_{10}H_{16}$, which has been found to be nearly pure *pinene*. The residual resin is soluble in two parts of warm alcohol of 57 per cent., and more copiously in absolute alcohol.

Tschirch and Wiegel investigated the constituents of Larch Turpentine. According to these investigators, this oleoresin contains from 60 to 64 per cent. of acid resins soluble in soda, from 20 to 22 per cent. of volatile oil, and from 14 to 15 per cent. of indifferent resin. The acid resins consist mainly of two isomeric amorphous bodies, *a*- and *b*-larinolic acid, $C_{18}H_{28}O_2$, and a smaller quantity of the crystalline *laricinolic acid*, $C_{20}H_{30}O_2$. The greater portion of the volatile oil boils between 155° and 170° C. (311° and 338° F.); a smaller quantity of higher boiling sesquiterpene commencing to boil at 190° C. (374° F.). The recently distilled oil has the sp. gr. 0.872, and possesses a characteristic turpentine odor. It is soluble in all proportions in alcohol and other solvents. (*A. Pharm.*, 1900, Aug. and Sept., 401, and 411, 487.) What is sold under the name of Venice turpentine, in commerce, is usually quite brown, and is a factitious substance, prepared by dissolving rosin in oil of turpentine. According to G. Fabris the nature of these spurious Venice turpentines can readily be detected by dissolving 5 Gm. of the sample in 20 mils of 95 per cent. alcohol, adding a few drops of phenolphthalein and sufficient of a 10 per cent. solution of potassium hydroxide to render it alkaline. With genuine Venetian turpentine a clear solution is obtained, while the spurious drug yields a turbid solution, from which, on standing, drops of oily resin separate.

5. Chian Turpentine.

Térébenthine de Chio, *Fr. Cod.*; Cyprischer Terpentin, *G.*; Trementina Cipria, *It.*

This variety of turpentine is collected chiefly in the island of Chio, or Scio, from the *Pistacia Terebinthus*, and it is said that the whole annual product of the island is only about two hundred and twenty-four pounds. During the summer the juice flowing spontaneously, or from incisions in the bark, falls upon smooth stones, or bundles of twigs, placed at the foot of the tree, from which it is procured by boiling and straining. After straining it is again boiled with a little water until all the water is evaporated, when it is finally poured into a vessel of cold water and kneaded. At first it is of a dirty yellow color, but after kneading it becomes quite white. (*P. J.*, xvi, 385.) The annual product of each tree is very small, and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious liquid, of a greenish-yellow color, or it occurs as a viscid opaque mass. The odor is peculiar, penetrating, and more agreeable than that of the other substances of the same class. The taste is mild, without bitterness or acrimony. Flückiger found nearly 14½ per cent. of essential oil, which contained a small quantity of an oxygenated oil. It leaves a glutinous residue when treated with strong alcohol. (Guibourt.) Its alcoholic solution does not redden litmus paper. (Martindale.) On exposure, liquid Chian turpentine speedily thickens, and ultimately concretes into a translucent solid, yellowish or yellowish-brown when in small pieces, greenish-brown in mass.

The odor of Chian turpentine is variously described. As the only tests we now have of the purity of the drug are its physical characteristics, and of these the odor is the most important, we give the following description by Wm. Martindale. (*P. J.*, April, 1880.) Chian turpentine "has when fresh a distinctive odor, slightly like the pinaceous turpentines, but much more agreeable and aromatic, according to some resembling citron and jasmine; but there is always a background smell like that of mastic, which becomes more developed and distinct with age, when it has lost the more volatile portion, the essential oil. According to Pereira, the turpentine-like odor is combined with the odor of fennel, and Guibourt says, when kept in a covered glass vessel the odor is strong and agreeable, analogous to that of fennel or the resin of elemi. It probably loses this rapidly. A specimen, bearing Guibourt's name, in the Ph. Society's Museum, has now no trace of it, but the mastic odor is very persistent. If the fennel odor be very evident in it I should fear the sample was not genuine, as in a statement made in the *Lancet* the writer says what is sold as Chian turpentine 'is either greatly adulterated or a wholly factitious article, manufactured from black resin, Canada balsam, and the essen-

tial oils of fennel and juniper. The taste of genuine Chian turpentine resembles that of mastic; it is agreeable and free from the characteristic bitterness and acridity of the pinaceous turpentines."

Besides the turpentines mentioned, various others are noticed in books on Materia Medica, though not found in commerce in this country. There are the *Strassburg turpentine,* much used in France, and obtained from the *Abies Picea* (*Abies pectinata* of De Candolle), or European silver fir, which grows on the mountains of Switzerland and Germany and bears a close resemblance, as well in its appearance as in its product, to *Abies balsamea* of Canada; the *Russian turpentine,* from *Pinus sylvestris;* the *Damara turpentine,* which speedily concretes into a very hard rosin, and is derived from *Pinus Damaris* Lam., the *Agathis damara* of Richard, growing in the East India islands; the *cowrie* or *cowdie* resin, procured by incision from another species of Agathis, *A. australis,* in New Zealand; and the *Dombeya turpentine,* a glutinous, milky-looking fluid, of a strong odor and taste, derived from the *Araucaria Dombeyi* of Richard, also called *Dombeya excelsa,* which inhabits Chili.

Finnan Turpentine, the oleoresin of *Pinus sylvestris,* is found by Tschirch and Niederstadt to consist of: 1.5 per cent. *silveolic acid,* $C_{14}H_{20}O_2$; 58 to 60 per cent. of *α-silvinolic acid,* $C_{15}H_{26}O_2$, and *β-silvinolic acid* ($C_{14}H_{24}O_2$); 20 to 21 per cent. of *resene;* 15 per cent. of volatile oil; and traces of bitter principle and succinic acid. Silveolic acid is crystalline; *α-* and *β-*silvinolic acids are both amorphous. The volatile oil has the sp. gr. 0.840 at 15° C. (59° F.), is soluble in all proportions in alcohol, ether, and chloroform, and is neutral when recently distilled, but becomes acid when exposed to the air. (*A. Pharm.,* 1901, ccxxxix, 167.)

Jura Turpentine.—A. Tschirch and E. Bruening have determined the following constituents of the oleoresin of *Picea vulgaris:* From 2 to 3 per cent. of *picea-pimarinic acid,* $C_{18}H_{30}O_2$; from 1.5 to 2 per cent. of *picea-pimaric acid,* $C_{20}H_{30}O_2$; from 48 to 50 per cent. of *α-* and *β-picea-pimarolic acid,* $C_{25}H_{44}O_2$; from 32 to 33 per cent. of volatile oil; from 10 to 12 per cent. of resene, $C_{21}H_{36}O$; and traces of succinic acid, coloring matter and bitter principle. (*A. Pharm.,* 238, Nov. 10, 1900, 616.)

Tschirch and Weigel (*A. Pharm.,* 1900, Aug. and Sept., 401, 411, 487) investigated Strassburg turpentine—the oleoresin of *Abies Picea;* it contains from 8 to 10 per cent. of an acid resin, *abieninic acid,* $C_{13}H_{20}O_2$; from 1.5 to 2 per cent. of a crystalline acid resin, *abietolic acid,* $C_{20}H_{28}O_2$; from 46 to 50 per cent. of two amorphous isomeric acid resins, *α-* and *β-abietinolic acid,* $C_{16}H_{24}O_2$; from 12 to 16 per cent. of a neutral resin, *abieto-resin;* and from 28 to 30 per cent. of volatile oil, together with traces of succinic acid, bitter principle, coloring matter, moisture and impurities. The oil when recently distilled has the sp. gr. 0.860, boiling between 148° and 165° C. (298.4° and 329° F.); the major fraction distils between 162° and 163° C. (323.6° and 325.4° F.). It has a greenish fluorescence and a lemon-like odor. When the oleoresin is distilled with potassium hydroxide a pleasant rose or orange-flower odor is developed, possibly due to the liberation of a fragrant alcohol.

Properties.—The turpentines resemble one another in odor and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation a volatile oil, called *oil of turpentine,* the composition of which is essentially uniform, it being composed of several terpenes (pinene, dipentene, and sylvestrene) of the formula $C_{10}H_{16}$, the residue consisting exclusively of rosin. (See *Oleum Terebinthinæ* and *Resina.*) Both the cones and leaves of *Abies Picea* yield oils known respectively as *pine cone oil* and *pine needle oil.* According to *Schimmel's Report* for April, 1897, they both contain pinene, limonene, and bornyl acetate. The oil from *Pinus sylvestris,* known as *fir oil,* also contains bornyl acetate to the amount of 12 per cent., according to *Schimmel's Report* for October, 1897, 47. On the other hand, the oil from *Larix Europæa,* known as *larch needle oil,* contains 8.1 per cent. of bornyl acetate and 6.14 per cent. of free borneol. (*Ibid.,* 61.)

Schiff affirms that the odor of turpentine is due to the presence of a product of oxidation, probably a camphoric aldehyde, $C_{10}H_{16}O_3$, which, with the odor, may be removed by shaking the turpentine with sodium bisulphite. A non-odorless turpentine may also be obtained by washing with solution of sodium hydroxide and distilling in an atmosphere of carbon dioxide. From the experiments of Faure, of Bordeaux, it appears that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia. (*Journ. de Chim. Méd.,* 1830, 94.) According to Thierry, the same result is obtained by the addition of one part of calcium hydroxide to thirty-two parts of common European turpentine. (*J. P. C.,* 3e sér., i, 315.) Crouzel (*P. J.,* 1892, 11) found tannin in the bark of *P. Pinaster,* associated with a peculiar reddish-yellow coloring matter, representing tannin in the process of formation.

Ed. Hirschsohn made experiments with the object of determining a reliable method for distinguishing artificial turpentine from the common, natural turpentine and larch turpentine, this becomes possible by the difference in the solvent effect of official ammonia water and alcohol, sp. gr. 0.863 at 15.6° C. (60° F.), upon them, under the conditions indicated in the following table:

Kind of Turpentine	Ammonia Solution (sp. gr. 0.960), 1 p. turpentine and 5 p. ammonia solution.	Alcohol (sp. gr. 0.863), 1 p. turpentine and 3 p. alcohol.
Venice turpentine	Is not disintegrated; produces a milky fluid in the water-bath.	Yields a nearly clear solution.
Common turpentine	Easily disintegrated, forming a milky mixture, then gelatinous; becomes clear in the water-bath.	Large quantities are deposited, but the mixture becomes clear in the water-bath.
Artificial turpentine	Is disintegrated, becomes clear in the water-bath for a moment, then turbid.	Turbid solution and precipitation; turbid in the water-bath with precipitation.

A mixture of common turpentine with larch (Venice) turpentine is recognized by the turbidity of, and precipitate from, the solution of 1 Gm. of the sample in 3 Gm. of alcohol sp. gr. 0.863. The same occurs if the common is replaced by artificial turpentine, but the latter is differentiated by ammonia, from the fact that in the presence of 20 to 30 per cent. of common turpentine the sample is easily disintegrated, and the solution becomes clear in the water bath, while in the presence of artificial turpentine the behavior is the same as with the pure Venice turpentine. (*Ph. Centralh.*, Nov. 26, 1903, 825 to 828.)

Uses.—The physiological activities of turpentines depend upon their volatile oils. They are so inconvenient of administration, and so variable in their activity that at present they are very rarely, if ever, used internally by regular practitioners of medicine. For an account of their physiological and therapeutic properties, see *Oleum Terebinthinæ*, p. 792. If given at all they should be administered in emulsion. Chian turpentine has been recommended as a specific in *cancer*, given in emulsion in doses of five grains (0.32 Gm.), increased *pro re nata*, and also applied locally. It is probably without value. Turpentine vapor baths have been found useful in the treatment of *chronic rheumatism;* they may be given by simply evaporating oil of turpentine in the ordinary cabinet or other vapor bath, or by driving the vapor through the fine branches and leaves of a terebinthinate plant. They probably differ in their action from the simple hot vapor bath by the stimulation of the skin due to the local action of the turpentine, and by the copious sweating which they produce. The bath should always be so arranged that the terebinthinate vapor is not inhaled by the patient.

Dose, twenty to thirty grains (1.3–2.0 Gm.).

TERPINI HYDRAS. U. S.

TERPIN HYDRATE Terpin. Hyd.

(tẹr-pī'nī hȳ'drăs)

"The hydrate [$C_{10}H_{18}(OH)_2 + H_2O$ = 190.18] of the dihydric alcohol terpin. Preserve it in well-closed containers, in a cool place." *U. S.*

Terpine, *Fr. Cod.;* Dihydrate de Térébenthène, Hydrate de Terpilène, *Fr.;* Terpinum hydratum, *P. G.;* Terpinhydrat, *G.;* Terpina, *Sp.*

In making terpin hydrate a mixture of four parts of rectified oil of turpentine, three parts of alcohol (sp. gr. 0.863), and one part of nitric acid is put in large, shallow porcelain dishes and allowed to stand for three or four days. The crystals which have formed are then collected and allowed to drain thoroughly; they are then pressed between sheets of absorbent paper, and crystallized from a cold solution in 95 per cent. of alcohol. The product is about 12 per cent. of the original turpentine oil. E. T. Hahn proposed the use of methyl alcohol (sp. gr. 0.801) in place of alcohol, in making terpin hydrate. (*A. J. P.*, 1897, 73.)

The anhydrous *terpin* $C_{10}H_{18}(OH)_2$, obtained from it by the loss of water has the characters of a glycol. Dipentene dihydrochloride is its hydrochloric acid ether. By the loss of water the terpin then becomes *terpineol*, $C_{10}H_{17}(OH)$, a liquid with an aromatic odor resembling lilac, and finally yields dipentene, terpinene, or terpinolene, according to the conditions of its treatment. Bouchardat and Voiry obtained terpineol in crystals which melt at 35° C. (95° F.) and remain in superfusion for long periods. (*Ann. Ch. Ph.*, 1893, 103.) For Wallach's researches on crystallized terpineol, see *P. J.*, 1893, 2.

L. Krentmann states that good results are obtained by replacing the alcohol in the process with hydrogen dioxide solution and subjecting the mixture poured into shallow dishes to light and air. The temperature should be carefully regulated so that the range will be between 15° and 20° C. (59° and 68° F.).

Terpin hydrate is officially described as in "colorless, lustrous, rhombic prisms, nearly odorless, and having a slightly aromatic and somewhat bitter taste. Efflorescent in dry air. One Gm. of Terpin Hydrate dissolves in about 200 mils of water, 13 mils of alcohol, 135 mils of chloroform and in 140 mils of ether at 25° C. (77° F.); also in about 34 mils of boiling water, 3 mils of boiling alcohol, and in about 1 mil of boiling glacial acetic acid. Heated slowly to about 100° C. (212° F.) it sublimes in fine needles. When quickly heated, it melts between 115° C. and 117° C. (239° and 242.6° F.), with the loss of water. It also loses its water of crystallization slowly over sulphuric acid. Add a few drops of sulphuric acid to a hot aqueous solution of Terpin Hydrate; the liquid becomes turbid and develops a strongly aromatic odor. Incinerate about 2 Gm. of Terpin Hydrate; not more than 0.05 per cent. of ash remains. Terpin Hydrate has no odor of

turpentine, and its saturated, hot, aqueous solution is not acid to litmus." *U. S.*

The pharmacy of terpin hydrate seems to be much misunderstood if one may judge by the liquid preparations on the market purporting to contain amounts of terpin hydrate impossible to be held in solution by the alcoholic strength of the preparation. It requires about 40 per cent. of alcohol in the finished preparation to hold in solution an amount of terpin hydrate corresponding to one grain to each fluidrachm.

Uses.—Terpin was first physiologically investigated by Lépine, in 1855, who found it to act both upon the mucous membranes and upon the nervous system in a manner similar to the oil of turpentine. It has since been used in *chronic bronchitis* and in the advanced stages of *acute bronchitis*, especially when the secretion is unusually free; also in *chronic cystitis* and *gonorrhea*.

Dose, two to five grains (0.13–0.32 Gm.), from four to six times a day, in pill or in emulsion.

TERRA SILICEA PURIFICATA. U. S.

PURIFIED SILICEOUS EARTH Ter. Sil. Purif. [Purified Kieselguhr, Purified Infusorial Earth]

(tĕr'rą sĭ-lĭ'cē-ą pū-rĭ-fī-cā'tą)

"A form of silica (SiO_2 = 60.30) consisting of the frustules and fragments of diatoms, purified by boiling with diluted hydrochloric acid, washing and calcining. It does not contain more than 10 per cent. of moisture. Preserve it in tightly-closed containers." *U. S.*

"Purified Siliceous Earth is a very bulky and very fine powder, white or of a pale light gray or pale buff color, without odor or taste. It readily absorbs moisture and will retain about four times its weight of water without the mixture becoming fluid. It is insoluble in water, acids or dilute alkaline solutions. Boil 10 Gm. of Purified Siliceous Earth with 50 mils of distilled water and filter the mixture; the filtrate is colorless and neutral to litmus. When ignited its color is not darkened (organic impurities) nor does it lose more than 10 per cent. of its weight (*moisture*). Add 1 Gm. of Purified Siliceous Earth to 25 mils of diluted hydrochloric acid; no effervescence occurs (*carbonate*) and, after boiling, and filtering, the filtrate is colorless, and separate portions, when tested, yield no precipitate with barium chloride T.S. (*sulphate*) and no blue color with potassium ferrocyanide T.S. (*iron*). Digest 1 Gm. of Purified Siliceous Earth, for fifteen minutes, with 20 mils of diluted hydrochloric acid and filter. Ten mils of the filtrate, when evaporated to dryness and ignited, does not leave a residue weighing more than 0.005 Gm." *U. S.*

Kieselguhr, infusorial earth or diatomaceous earth, as it is sometimes called, is found as a natural deposit of greater or lesser purity in many parts of the world. It should not be confounded with kaolin whose chemical composition and physical properties are quite distinct. It has wide-spread technical uses on account of its many valuable physical properties. On account of its high absorbent power and inertness, it is used to absorb nitroglycerin in the manufacture of dynamite. It is also used in transporting sulphuric acid without danger, as it forms a pulverulent compound consisting of seventy-five per cent. of sulphuric acid. It is used in fireproofing and insulating work on account of its incombustibility and non-conductivity. Its principal use in pharmacy is as a filtering medium for which it is very well suited in many ways (see *Talcum Purificatum*). It is also used in making dermatologic pastes.

THEOBROMINÆ SODIO-SALICYLAS. U. S. (Br.)

THEOBROMINE SODIO-SALICYLATE Theobrom. Sodio-Sal.

(thē-ō-brō-mĭ'næ sō-dĭ-ō-săl-ĭ-cȳ'lăs)

"Sodium theobromine [$C_7H_7O_2N_4Na$ = 202.10] and sodium salicylate [$NaC_7H_5O_3$ = 160.04], in approximately molecular proportions. It yields, when dried to constant weight in a desiccator over sulphuric acid, not less than 46.5 per cent. of theobromine [$C_7H_8O_2N_4$ = 180.10]. Preserve it in well-closed containers." *U. S.*

"Theobromine and Sodium Salicylate, $Na_2C_{14}H_{12}N_4O_5$, may be obtained by combining sodium hydroxide, theobromine, and sodium salicylate in molecular proportions. Should be preserved in stoppered, amber-colored bottles." *Br.*

Theobrominæ et Sodii Salicylas, Theobromine and Sodium Salicylate, *Br.*; Diuretin.

This compound, known also as *diuretin*, and also as *theonasal*, was the first of the soluble compounds of theobromine introduced into medicine.

Theobromine is a *dimethylxanthin* (dimethyloxypurin) isomeric with theophylline and differing in the location of the methyl groups which in theophylline are in the 1–3 position and in theobromine are in the 3–7 position. It is found in cacao beans in amounts ranging from 0.9 to 3.0 per cent., and in very much smaller amounts in kola nuts. It is also related to caffeine, which is a *tri-methyl xanthin*.

"Theobromine Sodio-Salicylate is a white, odorless powder, of a sweetish, saline, and somewhat alkaline taste. It gradually absorbs carbon dioxide from the air with the liberation of theobromine, becoming partially insoluble in water. One Gm. of Theobromine Sodio-Salicylate dissolves in 1 mil of water at 25° C. (77° F.); slightly soluble in alcohol. An aqueous solution of Theobromine Sodio-Salicylate (1 in 20) is colorless and clear or at most opalescent, and is strongly alkaline to litmus and phenolphthalein T.S. When ignited Theobromine Sodio-Salicylate yields a residue which colors a non-luminous flame intensely yellow and

effervesces with acids. An aqueous solution of Theobromine Sodio-Salicylate (1 in 100), slightly acidulated with acetic acid, becomes violet on the addition of ferric chloride T.S. Dissolve 1 Gm. of Theobromine Sodio-Salicylate in 10 mils of distilled water in a separator, add a few mils of sodium hydroxide T.S. and shake the mixture with 10 mils of chloroform. The residue obtained after the evaporation of the separated chloroform layer, when dried to constant weight at 80° C. (176° F.), does not exceed 0.005 Gm. (*caffeine*). About 0.1 Gm. of Theobromine Sodio-Salicylate dissolves in 2 mils of sulphuric acid without effervescing (*sodium carbonate*) and without producing more than a slight color (*organic impurities*)." *U. S.*

"A white amorphous powder. No odor; taste sweetish and alkaline. Soluble in 1 part of *water;* soluble in *alcohol* (90 per cent.); insoluble in *ether,* and in *chloroform.* Aqueous solution (1 in 4) alkaline to *litmus* and colorless; when acidified with *acetic acid* yields a violet coloration with *T. Sol. of ferric chloride;* when neutralised with *hydrochloric acid* gives a white precipitate of theobromine, and the filtrate from this, on the addition of more of the acid, gives a precipitate of salicylic acid; the precipitated theobromine, washed with a little *water,* yields, when treated with *potassium chlorate* and *hydrochloric acid* as described under 'Caffeina,' a purple color. The aqueous solution also yields precipitates with *T. Sol. of mercuric chloride,* with solutions of alkaloidal salts, and with *N/10 solution of iodine.*" *Br.*

"**Assay.**—Dissolve about 2 Gm. of Theobromine Sodio-Salicylate, previously dried to constant weight in a desiccator over sulphuric acid, and accurately weighed, in 10 mils of warm distilled water, and titrate the solution with normal hydrochloric acid V.S., phenolphthalein T.S. being used as indicator. Not more than 5.5 mils of normal hydrochloric acid V.S. is required to neutralize 2 Gm. of Theobromine Sodio-Salicylate. The solution should now be slightly alkaline to litmus or be made so by the addition of one or two drops of very dilute ammonia water. Allow it to stand at from 20° to 25° C. (68°–77° F.) for three hours, stirring occasionally, then transfer the precipitate of theobromine obtained to a dried and weighed filter of 9 cm. diameter, and wash the precipitate and filter with four successive portions of 5 mils each of ice-cold distilled water, afterwards dry the filter and contents at 100° C. (212° F.) and weigh. To the weight of precipitate thus obtained add for each 2 Gm. of salt, 0.13 Gm. (the approximate quantity of theobromine remaining in the liquid and washings). The sum corresponds to not less than 46.5 per cent. of the weight of dried Theobromine Sodio-Salicylate taken.

"About 0.05 Gm. of the precipitate obtained in the preceding assay, when evaporated to dryness on a water bath with 1 mil of hydrochloric acid and about 0.1 Gm. of potassium chlorate, leaves a reddish-yellow residue, which becomes purple on moistening with a drop of ammonia water. Another portion of about 0.2 Gm. of the precipitate, when slowly heated, volatilizes without melting and without leaving a weighable residue." *U. S.*

"Yields not less than 40 per cent. of theobromine and 35 per cent. of salicylic acid when tested by the following process: Dissolve 2 grammes of the Salicylate of Theobromine and Sodium in 10 millilitres of warm *water,* slightly acidify with *diluted hydrochloric acid,* add *solution of ammonia* until the reaction is faintly alkaline, and set aside for three hours at about 15.5° C. (60° F.), stirring frequently. Collect the precipitated theobromine on a tared filter, wash twice with 10 millilitres of *water,* dry at 100° C. (212° F.), and weigh the precipitate; it weighs not less than 0.8 gramme. Acidify the filtrate and washings with *hydrochloric acid,* shake with two successive quantities, each of 10 millilitres, of *ether,* evaporate the mixed ethereal solutions, dry the residue at 60° C. (140° F.), and weigh; it weighs not less than 0.7 gramme." *Br.*

Uses.—The effects of theobromine upon the system are very similar to those produced by caffeine except that it has relatively little influence upon the central nervous system. Because of this fact it is much less liable to produce wakefulness—although in some sensitive individuals it does act as a cerebral stimulant—and is not useful as a respiratory stimulant. The most important effect of theobromine upon the system is an increase in the secretion of urine. The mechanism of this action is doubtless the same as that of caffeine. Theobromine also is a powerful stimulant to the voluntary muscles, but because of its feeble effect upon the central nervous system is less useful than caffeine for the purpose of overcoming fatigue. It is used in medicine as a diuretic, especially in cases of *dropsy.* It is superior to caffeine in that because of its feeble influence over the central nervous system much larger doses can be administered than are permissible with caffeine.

Dose, from five to ten grains (0.32–0.65 Gm.), repeated at short intervals up to thirty or forty grains (2.0–2.6 Gm.) in 24 hours.

THEOPHYLLINA. U. S.

THEOPHYLLINE Theophyll. [Dimethylxanthine]

(thē-ō-phy̆l-lī'nạ)

"An organic base [$C_7H_8O_2N_4 + H_2O$ or 1 : 3 $C_5H_2(CH_3)_2O_2N_4 + H_2O = 198.12$], isomeric with theobromine. It is found in small amounts in the leaves of *Thea sinensis* Linné (Fam. *Ternstræmiaceæ*) and is also prepared synthetically." *U. S.*

Theophylline belongs to a group of organic compounds related to uric acid and known as diureides or xanthin bases. It is also known as 1–3, dimethyl, 2–6, dioxypurine, and differs from caffeine in having one less methyl group. It forms crystalline salts with hydrochloric and nitric acids and with a number of metallic

chlorides. It forms a soluble compound with sodium hydroxide. Caffeine may be prepared from it by methylation. It is prepared from the mother liquors of caffeine manufacture by precipitating a sparingly soluble silver compound which is later decomposed by hydrogen sulphide. The amount found naturally in tea is so small that most of the commercial product is of synthetic origin. It is made from ethyl cyanoacetate, which is the starting point for the synthesis of a number of the xanthine bases.

Properties.—"Theophylline occurs as a white, crystalline powder; odorless and having a bitter taste. It is permanent in the air. One Gm. of Theophylline dissolves in 100 mils of water and 80 mils of alcohol at 25° C. (77° F.). It is more readily soluble in hot water; sparingly soluble in ether. It is readily soluble in solutions of the alkali hydroxides and in ammonia water. A saturated aqueous solution of Theophylline is neutral to litmus. It melts between 269° and 272° C. (516.2° and 521.6° F.). Dissolve about 0.01 Gm. of Theophylline in 1 mil of hydrochloric acid in a porcelain dish, add 0.1 Gm. of potassium chlorate, evaporate the solution to dryness on a water bath and invert the dish over a vessel containing a few drops of ammonia water; the residue acquires a purple color which is destroyed by fixed alkalies. An aqueous solution of Theophylline yields a precipitate with tannic acid T.S. which is soluble in an excess of the reagent. Dissolve about 0.5 Gm. of Theophylline in 5 mils of potassium hydroxide T.S. and add 15 mils of a solution containing 0.5 Gm. of sulphanilic acid and 5 mils of hydrochloric acid in 100 mils of distilled water and then add 5 mils of an aqueous solution of sodium nitrite (1 in 200). When this mixture is brought nearly to boiling and sodium hydroxide T.S. is added, drop by drop, a blood red color is produced (distinction from *caffeine or theobromine*). A clear solution is produced when about 0.2 Gm. of Theophylline is dissolved in 5 mils of sodium hydroxide T.S. or in 5 mils of ammonia water (distinction from *caffeine, theobromine, or paraxanthine*). Theophylline loses not more than 9.5 per cent. of its weight when dried to constant weight at 100° C. (212° F.). Incinerate about 0.1 Gm. of Theophylline; no weighable ash remains. About 0.2 Gm. of Theophylline dissolves in 5 mils of sulphuric acid without producing more than a faint yellow color (*organic impurities*)." *U. S.*

Uses.—In its effects upon the system, theophylline acts almost the same as its isomer, theobromine (see p. 1123), and is used in medicine for precisely the same purposes. It appears, however, to be somewhat more irritant to mucous membrane, and is therefore more actively diuretic and also more likely to produce gastric disturbances. When used continuously over considerable periods of time the primary diuretic influence of theophylline may disappear, and the quantity of the urine return to its former low level, this despite increased doses of the drug. The explanation of this clinical observation is not yet forthcoming.

This drug is used almost exclusively in the form of one of its soluble compounds (see *Theocine Compounds,* Part II).

Dose, three to five grains (0.2–0.32 Gm.).

THYMOL. U. S., Br.

Thymol

(thȳ′mŏl)

"A phenol [$C_{10}H_{14}O$ or $C_6H_3(CH_3)(OH)(C_3H_7)$ 1:3:4 = 150.11] occurring in the volatile oil of *Thymus vulgaris* Linné (Fam. *Labiatæ*) and in some other volatile oils. Preserve it in well-closed containers." *U. S.* "Thymol, or isopropyl-metacresol, $C_{10}H_{14}O$, is a substance obtained from the volatile oils of Thymus vulgaris, *Linn.,* Monarda punctata, *Linn.,* and Carum copticum, *Benth. and Hook. f.* Purified by recrystallisation from alcohol." *Br.*

Acidum Thymicum; Thymic Acid; Thymol, Acide Thymique, *Fr. Cod.;* Thymolum, *P. G.;* Thymol, Thymiansaure, Thymolkampher, *G.;* Timolo, *It.;* Timol, *Sp.*

This substance has attracted considerable attention from its possession of antiseptic properties analogous to those of phenol, salicylic acid and creosote, with which it is also analogous in composition. It may be obtained by submitting the volatile oils of several plants to a prolonged refrigeration, under the influence of which it crystallizes. Thus, it has been obtained from *Monarda didyma* Linn., *M. punctata* and *Carum copticum* Benth. et Hook. *Ocimum viride* Willd., a plant which is used in Liberia as an antiperiodic, and is said to be especially valuable owing to the fact that when growing in a room it will drive mosquitoes out of the apartment, as well as the medicinally active *O. gratissimum* of India, probably depend for their activities upon thymol. (*Proc. A. Ph. A.,* xxvi, 168.) Thymol is obtained from any of the oils in which it occurs by distilling off from these the larger part of the hydrocarbons and adding warm sodium hydroxide solution to the residue, which combines with the thymol. The mixture is diluted after a time with hot water, which causes the unattacked oil to rise to the top. From the sodium hydroxide solution hydrochloric acid sets the thymol free. This collects as an oily layer, which on cooling will crystallize if a crystal of thymol is added.

Properties.—Thymol boils at 220° to 230° C. (428°–446° F.). It is very slightly soluble in water, but is very soluble in alcohol, and more freely in proportion to the concentration of the menstruum. It is dissolved by ether and the fixed oils, and has no rotatory power as regards polarized light. The alkalies unite with it to form soluble salts. Like creosote, it has the property of combining with animal tissues and thus protecting them against putrefaction. Its formula is $C_{10}H_{14}O$, or $C_6H_3\begin{cases}OH\\CH_3\\C_3H_7\end{cases}$; while *thymene,* with which it is associated in the oil, is a hydrocarbon, isomeric with the oil of

turpentine, and having the composition $C_{10}H_{16}$. As its formula indicates, it is a *propyl-cresol;* and it has been made synthetically by Widmann from cuminol (isopropyl benzaldehyde). This is first nitrated, then by means of phosphorus pentachloride the oxygen of the aldehyde group replaced by chlorine, the nitro group reduced, the chlorine replaced by hydrogen, and the amide group replaced by hydroxyl. The successive changes are thus indicated:

$$C_6H_4\begin{cases}C_3H_7\\COH\end{cases} \text{ to } C_6H_3\begin{cases}NO_2\\C_3H_7\\COH\end{cases}$$

$$C_6H_3\begin{cases}NO_2\\C_3H_7\\CHCl_2\end{cases} \text{ to } C_6H_3\begin{cases}NH_2\\C_3H_7\\CHCl_2\end{cases}$$

$$C_6H_3\begin{cases}NH_2\\C_3H_7\\CH_3\end{cases} \text{ to } C_6H_3\begin{cases}OH\\C_3H_7\\CH_3\end{cases}$$

A process has been patented by M. Dinesman for making *synthetic thymol* from *p* cymol (see *Ph. Centralh.,* Oct., 1901, 650).

Thymol is described in the U. S. P. "as in large, colorless, translucent, rhombic prisms, having an aromatic, thyme-like odor, and a pungent, aromatic taste, with a very slight caustic effect upon the lips. One Gm. of Thymol dissolves in 1010 mils of water, about 1 mil of alcohol, 0.7 mil of chloroform, 1.5 mils of ether, and in 1.7 mils of olive oil at 25° C. (77° F.); soluble in glacial acetic acid or in fixed or volatile oils. Its alcoholic solution (1 in 20) is neutral to litmus and is optically inactive. As a solid it is heavier than water, but when liquefied by fusion it is lighter than water. It melts between 48° and 51° C. (118.4° and 123.8° F.), remaining liquid at a considerably lower temperature. When it is triturated with about an equal weight of camphor or menthol, the mixture liquefies. When a very small crystal of Thymol is dissolved in 1 mil of glacial acetic acid, and then 6 drops of sulphuric acid and 1 drop of nitric acid are added, the liquid assumes a deep bluish-green color by reflected light. Heat about 1 Gm. of Thymol in a test tube in a water bath with 5 mils of a 10 per cent. solution of sodium hydroxide; a clear, colorless, or pale red solution is formed, which becomes darker on standing, without the separation of oily drops. Upon the addition of a few drops of chloroform to this solution and agitating the mixture, a violet color is produced. Volatilize about 2 Gm. of Thymol on a water bath; not more than 0.05 per cent. of residue remains. An alcoholic solution of Thymol (1 in 20) is not colored violet by ferric chloride T.S. (*phenol*)." *U. S.*

"Large, oblique prismatic crystals, sinking in water at 15.5° C. (60° F.). Melting point from 50° to 51° C. (122°–123.8° F.). Completely volatilised on a water-bath. Odor recalling that of thyme; taste pungent, aromatic. Almost insoluble in *water;* freely soluble in *alcohol* (90 per cent.), in *ether,* and in *solution of sodium hydroxide.* A solution of Thymol in half its volume of *glacial acetic acid,* warmed with an equal volume of *sulphuric acid,* assumes a reddish-violet color." *Br.*

Uses.—Thymol was originally introduced as a disinfectant for the same range of purposes for which phenol is employed. The advantage claimed for it was a more agreeable odor. Its drawbacks are its strong local irritant effect and its sparing solubility in water. Concerning its antibacterial powers the findings of different investigators have been contradictory, thus Cooper (*B. M. J.,* 1912, i, p. 1235) finds that in the presence of organic matter it is eight times as powerful as phenol and in the absence of organic matter twenty-five times as strong. On the other hand Schmidt (*Z. P. C.,* 1910, lxvi, p. 412) asserts that it has no germicidal value against vigorous bacteria. It is probably superior to phenol in antibacterial power. It is to-day rarely employed as a surgical disinfectant, but is an ingredient in many of the antiseptic mixtures intended for use upon mucous cavities, such as the National Formulary *Antiseptic Solution.* Its value for these purposes, however, is greatly reduced because of its powerful local irritant action; it is scarcely possible to apply it in stronger solution than one part in a thousand without considerable discomfort. Thymol is also used as a gastro-intestinal disinfectant in *fermentative gastritis, enteritis,* and similar conditions. For this purpose it may be given in doses of two to five grains (0.13–0.32 Gm.) several times a day. Perhaps the most important modern use of thymol is as a vermifuge. It is efficient against the *tape-worm* and probably all forms of intestinal parasites, but is especially employed against the *hook-worm.* For this purpose it is necessary to use it in such large doses that there is danger of poisoning unless absorption be guarded against. The method employed by the Porto Rican Commission as reported by Schultz (*J. A. M. A.,* 1911, lvii, p. 1102) was as follows: If the patient be fairly robust, from fifteen to thirty grains (1–2 Gm.) were given mixed with an equal quantity of sugar of milk, and administered on an empty stomach; this dose is repeated in two hours, and two hours later followed by a vigorous purge, either magnesium sulphate or compound cathartic pills. It is essential that the intestines be as empty as possible as the presence of various foodstuffs encourages absorption. Castor oil should be avoided as the cathartic for a similar reason. The symptoms of thymol poisoning are nausea, vomiting, headache, ringing in the ears, dizziness, muscular weakness, thready pulse, and fall of bodily temperature.

Dose, two to fifteen grains (0.13–1.0 Gm.).

THYMOLIS IODIDUM. U. S.

THYMOL IODIDE Thymol. Iod.

(thȳ-mō'lĭs ī-ŏd'ĭ-dŭm)

"Chiefly dithymol-diiodide [$C_{20}H_{24}O_2I_2$ or $(C_6H_2.CH_3.C_3H_7.OI)_2 = 550.03$]. It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 43 per cent. of iodine (I = 126.92). Preserve it in well-closed containers, protected from light." *U. S.*

Dithymoldiiodide; Aristol; Aristolum; Diiododithymol, *Fr. Cod.*; Dithymol Biiodé, *Fr.*; Dithymoljodid, Aristol, Annidalin, Thymotol, *G.*; Aristol, *Sp.*

Preparation.—*Thymol Iodide* contains about 45 per cent. of iodine; it is the product of the condensation of two molecules of thymol and the substitution of the hydrogen in the hydroxyl group in each by iodine. It may be prepared by decomposing a solution of iodine in potassium iodide by an alcoholic solution of thymol. For process, see *A. J. P.*, 1891, 175; *Proc. A. Ph. A.*, 1891, 572; *Bull. Pharm.*, 1891, 260. The Cincinnati Academy of Pharmacy published the following formula for thymol iodide: Thymol, 50 Gm.; potassium iodide, 58 Gm.; sodium hydroxide, 50 Gm.; water, to make 500 mils; solution of chlorinated soda, to make 3000 mils. Dissolve the thymol, potassium iodide, and sodium hydroxide in sufficient water, add the solution of chlorinated soda, collect the precipitate on a filter and wash it with water until it is free from chlorides. Remove the precipitate and dry it carefully at a temperature not exceeding 20° C. (68° F.). Reduce it to powder and keep it in a well-stoppered dark bottle. (*Am. Drug.*, 1898, 130.) The French Codex directs that two solutions be made, one by dissolving 16 Gm. of sodium hydroxide and 15 Gm. of thymol in sufficient water to make the solution measure 300 mils. The other solution is made by dissolving 60 Gm. of iodine and 80 Gm. of potassium iodide in enough water to make the solution measure 300 mils, the latter solution is added gradually to the alkaline solution of thymol with constant stirring; the resulting brown precipitate is washed with water and the product dried between 40° and 50° C. (104° and 122° F.).

Properties.—Thymol Iodide occurs as "a reddish-brown or reddish-yellow bulky powder with a very slight, aromatic odor. Thymol Iodide is insoluble in water or glycerin; slightly soluble in alcohol at 25° C. (77° F.); readily soluble in chloroform, ether, collodion or in fixed or volatile oils, leaving a slight residue. It is not soluble in solution of sodium hydroxide, either cold or warm. When heated with concentrated sulphuric acid, it is decomposed with the separation of iodine. Dried to constant weight in a desiccator over sulphuric acid, it loses not more than 5 per cent. of its weight. Incinerate about 0.5 Gm. of Thymol Iodide in a porcelain crucible at a temperature not exceeding a low red heat; not more than 1.5 per cent. of ash remains. Shake about 0.1 Gm. of Thymol Iodide for one minute with 20 mils of distilled water and filter. The filtrate does not become more than opalescent on the addition of a few drops of nitric acid and silver nitrate T.S. (*halogen salts*). Shake about 0.5 Gm. of Thymol Iodide with 10 mils of distilled water and filter the mixture; the filtrate is not alkaline to litmus (*alkalies*), nor is it colored blue upon the addition of a few drops of starch T.S. (*free iodine*).

Assay.—Mix thoroughly about 0.25 Gm. of Thymol Iodide, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, with about 3 Gm. of anhydrous sodium carbonate. Cover the mixture with about 1 Gm. more of anhydrous sodium carbonate and heat it moderately, in a crucible, gradually increasing the heat, but not exceeding a dull redness, until the mass is completely carbonized. When sufficiently cooled, extract the residue with boiling distilled water and wash it on a filter with boiling distilled water until the washings cease to produce an opalescence with silver nitrate T.S. Heat the combined washings, which measure about 150 mils, on a water bath and add an aqueous solution of potassium permanganate (1 in 20) in small portions, until the hot liquid remains permanently pink. Then add just enough alcohol to remove the pink tint, cool the liquid to room temperature, and dilute it to 200 mils. Mix it well and then filter through a dry filter, rejecting the first 50 mils of filtrate. To 100 mils of the subsequently clear filtrate add about 1 Gm. of potassium iodide (free from iodate) and an excess of diluted sulphuric acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate V.S., adding starch T.S. near the end of the titration. It shows, in the dried Thymol Iodide, not less than 43 per cent. of I.

"Each mil of the tenth-normal sodium thiosulphate V.S. used corresponds to 0.002115 Gm. of I. Each gramme of Thymol Iodide corresponds to not less than 203.3 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

Osseward (*Proc. A. Ph. A.*, 1901, 176) obviates the difficulty of obtaining smooth ointments of thymol iodide (which most dispensers have experienced when proceeding in the usual way) by adding sufficient ether to 1 oz. of thymol iodide placed in a dry mortar, to form a paste, then stirring in 1 oz. of olive oil until a smooth paste is obtained; the ether can be dissipated during the stirring, and this 50 per cent. mixture used in making ointments by incorporating with fatty substances.

Uses.—Thymol iodide is used as a non-toxic and non-irritant dusting powder for *wounds*. It has the same range of usefulness for this purpose as iodoform over which it has the great advantage of being comparatively odorless. According to Shamberg and Kolmer (*J. A. M. A.*, 1914, lxii, p. 1950), it restrains the growth of *Staphylococcus aureus* when present in the proportion of 0.5 per cent. Despite, however, its superiority in direct antiseptic action to iodoform, it is not held in as high esteem by most surgeons. It is also used as a dusting

powder in various moist *skin diseases,* such as weeping eczemas, and Daxenberger (*Heilkunde,* 1908) recommends a 10 per cent. solution in olive oil as a local application in *atrophic rhinitis* and *fissure in ano* as well as various *skin diseases.*

Dose, from two to three grains (0.13–0.2 Gm.).

THYROIDEUM SICCUM. U. S., Br.

DRIED THYROIDS Thyroid. Sicc. [Glandulæ Thyroideæ Siccæ, U. S. VIII Desiccated Thyroid Glands]

(thȳ-roi-dē'ŭm sĭc'cŭm)

"The thyroid glands of animals which are used for food by man, freed from connective tissue and fat, dried and powdered, and containing not less than 0.17 per cent. nor more than 0.23 per cent. of iodine (I = 126.92) in thyroid combination. One part of Dried Thyroids corresponds to approximately 5 parts of the fresh glands." *U. S.* "Dry Thyroid is a powder prepared from the fresh and healthy thyroid glands of the sheep. Remove the external fat and connective tissue from the thyroid glands taken from the sheep immediately after killing. Cut the glands across, and reject any which contain cysts, are hypertrophied, or are otherwise abnormal. Mince finely the healthy glands, and dry at a temperature of 30° to 40° C. (86°–104° F.); powder the dried product; remove all fat by washing with *petroleum spirit;* again dry the residue." *Br.*

Dry Thyroid; Getrocknete Schilddrüsen, *G.*

Desiccated thyroid glands were introduced into the U. S. P. VIII for the first time; the British Pharmacopœia introduced this preparation in the 1898 and 1914 editions. The process for dry thyroid is given above; the objection to its use is that the powder may contain bacteria, or even ptomaines, if great care is not used in its preparation; it is also stated that glycerin does not dissolve all of the thyroiodin which is the principal active constituent, and "Thyroid Solution" cannot be thoroughly representative.

See *Liquor Thyroidei,* Br., 1898, *U. S. Disp.,* 19th edition, page 740.

Properties.—Dry thyroid is officially described as "a yellowish, amorphous powder, having a slight, characteristic odor. Dried Thyroids must be free from iodine in inorganic or any other form of combination than that peculiar to the thyroid. Dried Thyroids contain not more than 6 per cent. of moisture and the yield of ash does not exceed 5 per cent.

"Assay.—Mix 1 Gm. of Dried Thyroids in a nickel crucible of about 125 mils capacity, with 15 Gm. of a mixture composed of 138 parts by weight of anhydrous potassium carbonate, 106 parts of anhydrous sodium carbonate and 75 parts of potassium nitrate. Spread an additional 5 Gm. of this fusion mixture evenly over the surface. Heat the crucible over a free Bunsen flame until no further carbonization is observed, cool it and dissolve the residue in about 150 mils of distilled water, warming to hasten solution. Transfer this solution to an Erlenmeyer flask, of about 500 mils capacity and add approximately 50 mils, or its equivalent, of a fresh solution of chlorinated soda (containing 2.4 per cent. of chlorine by weight). Now treat the mixture with enough phosphoric acid, diluted with an equal volume of distilled water, to produce an appreciable yellow tint of free chlorine, then add 10 mils more of the phosphoric acid diluted with an equal volume of distilled water, and boil the contents of the flask for one-half hour or until the volume has been reduced to about 150 mils. Cool the liquid, add 10 mils of an aqueous solution of potassium iodide (1 in 100) and titrate the liberated iodine with freshly prepared two-hundredth-normal sodium thiosulphate V.S., starch T.S. being used as indicator just before the end of the reaction. It shows not less than 0.17 per cent. nor more than 0.23 per cent. of I.

"Each mil of two-hundredth-normal sodium thiosulphate V.S. used corresponds to 0.1058 milligramme of I derived from the Thyroid Glands used. Each gramme of Dried Thyroids corresponds to not less than 16.07 mils nor more than 21.74 mils of two-hundredth-normal sodium thiosulphate V.S." *U. S.*

"A light, dull-brown powder, with a very faint meat-like odor and taste; free from any flavor of putrescence. Liable to become damp on exposure to the air, and to deteriorate." *Br.*

Many preparations of the thyroid glands are upon the market, most of which are powders or so-called standardized extracts. The active principles have not been isolated in such a state of purity as to admit of accurate description.

The chemical nature of the active principle of thyroid gland is unknown. The substance isolated by Baumann (*Z. P. T.,* 1895, xxi) and called by him *thyro-iodine* (*iodothyrin*), is by many believed to represent the activities of the gland. But while it undoubtedly possesses many of the properties of thyroid gland there is strong evidence that it will not set aside all of the symptoms of thyroidectomy. Moreover it does not appear to be, strictly speaking, a chemical individual since it may contain varying proportions of iodine. Pick and Pilenes (*Z. E. P. T.,* 1909, vii, p. 518), prepare a *thyroglobulin* by macerating the thyroid gland in normal salt solution and precipitating after some weeks the globulins with ammonium sulphate which they assert will set aside fully developed myxedema. *Iodoglobulin* is apparently simply an aqueous extract of the thyroid gland. E. C. Stanford (*Y. B. P.,* 1898, p. 354) gives the following process for preparation of *thyroglandin* which is practically the same thing as iodoglobulin.

"The thyroid glands, freed from fat and minced, are first macerated in four to five times their weight of cold water, using ice if necessary in summer to keep down the temperature to 10° C. (50° F.), for twenty-four hours, and this maceration is repeated. The solutions are filtered off and evaporated to dryness at a tem-

perature not exceeding 100° C. (212° F.). The extract is powdered, and represents the iodo-globulin and a small proportion of saline matter. The residue from the cold water maceration is boiled for one hour with a 1 per cent. solution of sodium hydroxide (in the proportion of 1 per cent. of sodium hydroxide to the original weight of the glands). The solution is allowed to cool to deposit the fat, and filtered off. This solution is then carefully neutralized with hydrochloric acid and evaporated to dryness at 100° C. (212° F.); the residue, which contains all the thyroiodin, is then powdered and mixed with the iodo-globulin obtained in the first process. The resulting powder is thyroglandin."

Beebe finds in thyroglobulin a substance which he calls *thyroprotein*, and believes to be the active principle. Whatever be the precise nature of this active principle, it is apparent that it is an iodine-containing body, and although the quantity of iodine does not furnish an altogether trustworthy guide to the quality of thyroid body, a sample of the drug with a low content of organic iodine may be rejected as of inferior quality.

Kendall (*J. Bi. Chem.*, 1915, xx, 501) claims to have separated the iodine-containing principle of the thyroid in a crystalline form. He believes it to be a diiodo-dihydroxy-indol. Its melting point is 220° C. (428° F.), and it contains 60 per cent. of iodine. It produces tachycardia, loss of weight, and nervous irritability. The effective dose is very small; in a cretin weighing forty pounds a dose of 11 Mgm. distributed over a period of fourteen days caused an increase in the pulse rate from 90 to 140.

Uses.—It has been proved upon the human being by Kocher, of Berne, and upon monkeys by Horsley, of London, that the removal of the thyroid body is followed by the production of increasing weakness, associated with swelling of the body, enlargement and thickening of the skin, mucoid exudation into the subcellular tissue, and a very extraordinary slowing of all functions—a condition which progresses until the subject sinks into a state of complete apathy, with subnormal temperature and failure of all vital functions. This congeries of symptoms is the same as that previously described under the name of *myxœdema* by Ord.

It is probable that when the secretion of the thyroid gland is diminished to a slight extent, not sufficient to give rise to myxedematous symptoms, there is more or less modification in various functions of the body. On the other hand, the administration of thyroid gland to normal animals or men causes well marked symptoms which we may speak of as the physiological action of thyroid. There is strong reason to believe that the symptoms of Graves's disease are due to an excessive secretion of the thyroid gland.

The single dose of thyroid produces no very obvious changes in the bodily functions, although Asher and Flack (*Z. B.*, 1911, lv, p. 83) have shown that there is an increased irritability of the vasomotor center; that is, that the response both to pressor and depressor influences is greater than normal. The most marked result following the continued use of the thyroid gland is a diminution in the bodily weight. Simultaneously with the loss of weight there is an increase in the output of nitrogenous and phosphatic elements of the urine indicating an augmented protein catabolism. The increase in the nitrogenous elimination is not, however, sufficient to account for the loss in bodily weight; it has been estimated that from one-sixth to one-third of the loss of weight can be attributed to the increased destruction of protein tissue. The natural conclusion is that there is an even greater oxidation of the adipose tissue of the body. This view is confirmed by the experiments of Magnus-Levy (*D. M. W.*, 1896), who has demonstrated a great increase in the amount of carbonic acid expired. There are also more or less marked changes in the blood, the most being an increase in the mononuclear leukocytes either with or without an increase in the total number of white corpuscles. Hunt and Seidell (*J. P. Ex. T.*, 1910, ii, p. 15) have shown that thyroid feeding alters the resistance of mice to certain poisons, diminishing the susceptibility to acetonitril, but increasing that to morphine. They have suggested this reaction as a test of the activity of samples of the drug.

Among the conditions for which thyroid gland has been found clinically useful stand pre-eminent those states which are due to an absence of its secretion. These symptoms when occurring in adult life, either as the result of degenerative changes in the gland or of unwise surgical procedures, are known as *myxedema*, but when due to a congenital absence are called *cretinism*. In these cases, especially the congenital group, most striking improvement follows the continued use of thyroid feeding. As the thyroid failure is usually permanent it is necessary to continue the use of the drug throughout the patient's life. Our knowledge of the effects of thyroid feeding would seem to strongly indicate the use of the drug in the treatment of *obesity*. Unfortunately, however, although there is in the majority of cases a rapid loss of weight under the thyroid treatment for a short period of time, the system soon becomes inured to the action of the drug, and despite its continued use even in ascending doses the patient may regain the lost weight. It is, however, often of service in conjunction with the dietetic and hygienic measures suitable for this class of cases, but much harm has been done by the proprietary anti-fat remedies containing thyroid as the active ingredient. It is by far too powerful a drug to be used except under medical supervision. As pointed out above, the thyroid gland also has apparently some relation with the sexual organs, and it has been found clinically useful in certain uterine disorders, notably *metrorrhagia*. There are few diseases, either chronic or acute, in which the thyroid gland has not been recommended. Among those conditions in which its value is more or less substantiated may be mentioned diseases of the bones,

as *ununited fractures, osteomalacia,* and *rheumatoid arthritis,* certain skin diseases especially *psoriasis, hay fever, asthma, cancer, hemophilia,* etc.

In view of the uncertainty concerning the nature of the active principle of this drug we believe that it is much better to use the official dried gland than any of the many proprietary preparations. In myxedema it is generally well to begin with relatively large doses, about five grains (0.32 Gm.) until the accumulated symptoms due to the prolonged lack of thyroid secretion have abated, and afterwards continue the use of the drug in smaller quantities. For other conditions it is generally well to begin with smaller doses, two or three grains (0.13–0.2 Gm.), three times a day, gradually increasing if necessary, until palpitation of the heart or excessive nervousness indicates that the physiological limit or the therapeutic purpose is obtained. In any case, during the administration of the drug the occurrence of any of the symptoms of hyper-thyroidism should be the immediate signal for the withdrawal of the drug.

Among the various preparations of thyroid upon the market may be mentioned *iodothyrin* (*thyro-iodine*). As this appears commercially it is diluted with milk sugar to a strength equal to that of the fresh gland. The dose is ten to thirty grains (0.65–2.0 Gm.). *Thyroprotein,* standardized to contain 0.33 per cent. of iodine. *Thyraden,* dose two to eight grains (0.13–0.5 Gm.). *Thyrein,* said to be identical with iodothyrin. *Thyroidin,* a commercial preparation corresponding to the official dried gland. *Thyreoidin* Notkin, dose, one-sixth grain (0.01 Gm.). It is said also to be useful for hypodermic administration in the form of a one-half per cent. solution. *Thyron* or *tyron,* prepared by treating thyroid gland with tannic acid.

Dose, of dried thyroids, from two to five grains (0.13–0.32 Gm.).

TINCTURA ACONITI. U. S., Br.

TINCTURE OF ACONITE Tr. Aconit. [Aconiti tinctura P. I.]

(tĭnc-tū'rą ăc-o-nī'tī)

"*One hundred mils* of Tincture of Aconite yields not less than 0.045 Gm. nor more than 0.055 Gm. of the ether-soluble alkaloids of aconite. If assayed biologically the minimum lethal dose should not be greater than 0.0004 mil for each gramme of body weight of guinea-pig." *U. S.* "Tincture of Aconite contains in 100 millilitres 0.04 gramme of the ether-soluble alkaloids of Aconite Root." *Br.*

Tinctura Aconiti Radicis, *U. S.* 1870; Tincture of Aconite Root; Teinture de racine d'Aconit, *Fr. Cod.*; Tinctura Aconiti, *P. G.*; Akonittinktur, Eisenhuttinktur, *G.*; Tinctura di aconito, *It.*; Tintura alcoholica de aconito, *Sp.*

* "Aconite, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using a mixture of *seven volumes* of alcohol and *three volumes* of water as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.05 Gm. of the ether-soluble alkaloids of aconite." *U. S.*

"Aconite Root, in No. 40 powder, 150 *grammes;* Alcohol (70 per cent.), *a sufficient quantity.* Moisten the powder with seventy-five millilitres of the Alcohol, and produce, by the *percolation process,* one thousand millilitres of a strong tincture. Determine the proportion of ether-soluble alkaloids present in this strong tincture, by evaporating one hundred millilitres to dryness in a shallow porcelain evaporating basin, and proceeding as directed under 'Aconiti Radix.' Dilute the remainder of the strong tincture with sufficient of the Alcohol to produce a Tincture of Aconite containing 0.04 gramme of ether-soluble alkaloids in 100 millilitres of the Tincture. Examined by the foregoing process Tincture of Aconite is found to contain in 100 millilitres 0.04 gramme of the ether-soluble alkaloids of Aconite Root. *Limit of error* 0.002 gramme in excess or defect. This Tincture is of approximately the same strength as the Tinctura Aconiti of the International Agreement, and about twice as strong as the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

Assay. U. S. P. IX.—"Evaporate 150 mils of Tincture of Aconite at a temperature not exceeding 75° C. (167° F.), until it measures about 20 mils. Add 10 Gm. of purified sawdust (see Reagents, Part III) to this liquid, incorporate it thoroughly and then continue the evaporation until the sawdust is dry. Transfer the impregnated sawdust to a 250 mil flask, add 150 mils of ether and proceed as directed in the assay under *Belladonnæ Radix,* page 222, fourth line of the Assay, modifying the process there given by using the ammonia water with a small quantity of distilled water to rinse out the dish in which the mixture was evaporated, and use ether only in the final extraction of the alkaloids. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 64.539 milligrammes of the ether-soluble alkaloids of aconite. For an alternative method of assaying Tincture of Aconite, see Biological Assays (Part III)." *U. S.*

Robinson (*A. I. M.,* 1915, xv, p. 645) has found that the substance separated by the U. S. P. method of assaying aconite and giving the chemical test for aconitine, had a minimal lethal dose at least forty-five times as much as that of crystalline aconitine. This fact emphasizes the necessity of physiological standardization of aconite. For description of biological assay, see *Aconitum.*

The old tincture of the U. S. Pharmacopœia, 1890, had seven times the strength of the British, and the title was changed from *Tinctura Aconiti Radicis* to *Tinctura Aconiti* in the U. S., 1880, revision. It was much stronger than the Tincture of Aconite Leaves, which is still used occasionally, and made of the strength of two troyounces of powdered aconite leaves in a pint of diluted alcohol, and too much caution cannot

be observed to avoid mistaking one tincture for the other. A very important change was made in the strength of Tincture of Aconite in the U. S. P. VIII. The former 35 per cent. tincture was replaced by a tincture of 10 per cent., which is now the strength of the official tincture, 1914. A chemical assay process was also appended and the U. S. P. IX further recommends a biological standard and assay. The latter is desirable because faulty manipulation or storage changes the aconitine to inert bodies, and this would not be detected by the chemical assay. In preparing it, each step of the process must be carefully attended to. The root should be thoroughly comminuted, and very carefully packed in the percolator, and the displacing menstruum very gradually added. Tartaric acid which was formerly used in accordance with the researches of Duquesnel in the U. S., 1880, tincture has been abandoned, as it was found to be unnecessary. For a paper on Tincture of Aconite, by M. I. Wilbert, see *Proc. A. Ph. A.*, 1902, 348. The external use of the tincture requires care, as serious symptoms have followed its too free employment. (Case, *B. M. S. J.*, Feb., 1872, 74.)

Fleming's Tincture of Aconite.—This should always be expressly designated when prescribed. It is considerably stronger than the official; and several deaths have occurred from the use of it. The following is Fleming's formula: Take of the root, carefully dried and finely powdered, *sixteen (troy) ounces;* Alcohol, *sixteen fluidounces.* Macerate for four days, put into a percolator, and add alcohol until twenty-four fluidounces are obtained. Not more than two drops of this should be given as a commencing dose, to be increased till its peculiar effects are experienced.

Dose, U. S. tincture, 3–10 min. (0.2–0.6 mil); Br. tincture, 5–15 min. (0.3–0.9 mil); if frequently repeated, 2–5 min. (0.12–0.3 mil).

TINCTURA ALOES. U. S.

TINCTURE OF ALOES Tr. Aloes

(tĭnc-tū'rą ăl'ō-ēs)

Teinture (alcoolé) d'Aloés, *Fr. Cod.;* **Tinctura Aloës,** *P. G.;* **Aloetinktur,** *G.;* **Tinctura alcoholica de acibar,** *Sp.*

* "Aloes, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Glycyrrhiza, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains] to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using diluted alcohol as the solvent." *U. S.*

Tincture of aloes was deleted from the Br. Pharm., 1914. The process of the previous British Pharmacopœia is appended.

"Extract of Barbados Aloes, *½ ounce* (Imperial) or 25 grammes; Liquid Extract of Liquorice, 3 *fl. ounces* (Imp. meas.) or 150 cubic centimetres; Alcohol (45 per cent.), *a sufficient quantity.* Place the Extract of Barbados Aloes in a closed vessel with *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol; set aside for forty-eight hours, occasionally shaking until dissolved; add the Liquid Extract of Liquorice; filter; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*, 1898.

The strength of the British tincture, 1898, was only one-fourth that of the U. S. tincture. The formula of the U. S. (8th Rev.) directed glycyrrhiza instead of extract of licorice, but has returned to the process of maceration for its preparation. Ménière says of the tincture of aloes that it deposits crystals of aloin, which adhere to the sides of the bottle, and in the upper part of it a yellow resinous matter is seen.

Dose, as a purgative, from two to four fluidrachms (7.5–15.0 mils); as a laxative, from one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA ALSTONIÆ. Br.

TINCTURE OF ALSTONIA

(tĭnc-tū'rą ăl-stōn'i-æ)

"Alstonia, in No. 20 powder, 125 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture represents whatever therapeutic properties alstonia bark may possess. It is used in *malaria.*

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA ARNICÆ. U. S. (Br.)

TINCTURE OF ARNICA Tr. Arnic. [Tinctura Arnicæ Florum, U. S. 1890]

(tĭnc-tū'rą är'nĭ-çæ)

Tinctura Arnicæ Florum, *Br.*, Tincture of Arnica Flowers; Teinture (alcoolé) de Fleur d'Arnica, Teinture d'Arnica, *Fr. Cod.;* Tinctura Arnicae, *P. G.;* Arnikatinktur, *G.;* Tintura di Arnica, *It.;* Tintura alcoholica de arnica, *Sp.*

* "Arnica, in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Moisten the drug with *five hundred mils* [or 16 fluidounces, 435 minims] of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand well covered for twenty-four hours, then pack it with moderate pressure and allow the percolation to proceed slowly, pouring on additional diluted alcohol as needed. When the percolate measures *two hundred and fifty mils* [or 8 fluidounces, 218 minims] stop the flow, macerate the drug for an additional twenty-four hours, and then continue the percolation until the total percolate measures *five hundred mils* [or 16 fluidounces, 435 minims]. Again interrupt the percolation, macerate the drug for another twelve hours and afterwards collect an additional *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of percolate. Again macerate the drug for twelve hours and then allow the percolation to proceed slowly, pouring on sufficient diluted alcohol to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Arnica Flowers, in No. 20 powder, 100

grammes; Alcohol (45 per cent.), sufficient to produce 1000 *millilitres*. Moisten the powder with two hundred *millilitres* of the Alcohol, and complete the *percolation process.*" *Br.*

The U. S. IX and Br. Pharm., 1914, have dropped arnica root and tincture of arnica flowers alone represents arnica in both Pharmacopœias. *Tincture* of *Arnica Root,* Br., 1898, was made by percolating 50 grammes powdered arnica rhizome with 70 per cent. alcohol, until one thousand mils were obtained. Tincture of arnica root was solely intended for internal administration and confusion arose from the similarity in names.

The U. S. P. tincture of arnica differs from that official in 1870 in the menstruum selected, which is now diluted alcohol in place of alcohol. The change was advocated by numerous pharmaceutical writers, and there is no question of the ability of the menstruum to exhaust the arnica flowers, if they are tightly packed in the percolator. The principal objection to the change is the greater difficulty that will be experienced in mixing the tincture with liniments containing oily and alcoholic liquids.

Either alone, or diluted with water, soap liniment, etc., tincture of arnica is often applied popularly to *bruises, sprains, tumors* and local *rheumatic pains,* under the impression that it has extraordinary healing powers. It probably acts merely as a counter-irritant. On some skins it produces a violent eczematous inflammation. If given internally, the *dose* would be from ten to thirty minims (0.6–1.8 mils), increased until some effect was produced.

Dose, of the British tincture of the root, twenty minims to half a fluidrachm (1.3–1.8 mils).

TINCTURA ASAFŒTIDÆ. U. S. (Br.)

TINCTURE OF ASAFETIDA Tr. Asafœt.

(tĭnc-tū'rą ăs-ą-fœt'ĭ-dæ)

Tinctura Asafetidæ, *Br.;* Teinture (alcoolé) d'Asafœtida, *Fr. Cod.;* Asanttinktur, Stinkasanttinktur, *G.;* Tinctura alcoholica de asafetida, *Sp.*

* "Asafetida, bruised, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using alcohol as the solvent." *U. S.*

"Asafetida, bruised, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Macerate the Asafetida in a closed vessel with *seven hundred and fifty millilitres* of the Alcohol for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

This tincture becomes milky on the addition of water, in consequence of the separation of the resin.

Dose, thirty minims to a fluidrachm (1.8–3.75 mils).

Off. Prep.—Mistura Magnesii, Asafœtidæ et Opii, *N. F.*

TINCTURA AURANTII AMARI. U. S. (Br.)

TINCTURE OF BITTER ORANGE PEEL Tr. Aurant. Amar.

(tĭnc-tū'rą âu-răn'tĭ-ī ą-mā'rī)

Tinctura Aurantii, *Br.;* Tincture of Orange; Teinture (alcoolé) d'Ecorce d'Orange amère, *Fr.;* Tinctura Aurantii, *P. G.;* Pomeranzentinktur, Pomeranzenschalentinktur, *G.*

* "Bitter Orange Peel, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *three volumes* of alcohol and *two volumes* of water as the menstruum." *U. S.*

"Fresh Bitter-Orange Peel, cut small, 250 *grammes;* Alcohol (90 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

It is the peel of the Seville orange that is directed in this process, and the outer part only is active. The substitution of fresh for dried orange peel was proposed in England, and its propriety considerably discussed. (See *P. J.,* Nov. 9, 1872, also April 4, 1874.) Indeed, it met with so much favor as to be introduced in the 1885 revision of the British Pharmacopœia, and was used in the *Tinctura Aurantii Recentis,* Br.; but in the Br. Pharm., 1898, the name was changed to *Tinctura Aurantii.* The two tinctures differ also because of the fact that the Br. "orange peel" is only of the outer layer, while the U. S. includes also the inner, white, portion of the rind. The U. S. tincture has a greenish-brown color and a bitterish taste, the latter due to the presence of hesperidin from the inner layer of the rind. The Br. tincture of orange more closely resembles the U. S. *Tinctura Aurantii Dulcis* in sensible properties. The tincture of bitter orange peel is employed as a grateful addition to infusions, decoctions, and mixtures.

Dose, from one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Syrupus Aromaticus, *Br.;* Syrupus Aurantii, *Br.;* Elixir Aurantii Amari, *N. F.*

TINCTURA AURANTII DULCIS. U. S.

TINCTURE OF SWEET ORANGE PEEL Tr. Aurant. Dulc.

(tĭnc-tū'rą âu-răn'tĭ-ī dŭl'cĭs)

Teinture de Zeste d'Orange douce, *Fr.;* Apfelsinenschalentinktur, *G.*

* "Sweet Orange Peel, grated from the fresh fruit, *five hundred grammes* [or 17 ounces av., 279 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), macerating the drug in *one thousand mils* of alcohol and completing the preparation with alcohol. Use purified cotton as the filtering medium." *U. S.*

This tincture was designed to furnish a highly

flavored alcoholic preparation of orange and has no medicinal properties. It is used as a pleasant adjuvant and flavoring agent.

Off. Prep.—Syrupus Aurantii, *U. S.*

TINCTURA BELLADONNÆ FOLIORUM. U. S. (Br.)

TINCTURE OF BELLADONNA LEAVES Tr. Bellad. Fol. [Belladonnæ tinctura P. I.]

(tĭnc-tū'rą bĕl'lą-dŏn'næ fō-lī-ō'rŭm)

"*One hundred mils* of Tincture of Belladonna Leaves yields not less than 0.027 Gm. nor more than 0.033 Gm. of the total alkaloids of belladonna leaves." *U. S.* "Tincture of Belladonna contains in 100 millilitres 0.035 *gramme* of the alkaloids of Belladonna Leaves." *Br.*

Tinctura Belladonnæ, *Br., U. S. P.* 1880; Tincture of Belladonna; Teinture de feuille de Belladone, *Fr. Cod.;* Belladonnatinktur, *G.;* Tintura alcoholica de belladonna, *Sp.*

* "Belladonna Leaves, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using diluted alcohol as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.03 Gm. of the total alkaloids of belladonna leaves." *U. S.*

"Belladonna Leaves, dried and in No. 20 powder, 100 *grammes;* Alcohol (70 per cent.) sufficient to produce 1000 *millilitres.*

"Moisten the Belladonna Leaves with one hundred millilitres of the Alcohol, and complete the *percolation process.* Determine the proportion of alkaloids contained in the tincture so prepared by the Br. process below." *Br.*

"**Assay.**—Evaporate 100 mils of Tinctura of Belladonna Leaves on a water bath until it measures about 10 mils, transfer the evaporated liquid to a separator, and proceed as directed in the assay under *Fluidextractum Belladonnæ Radicis,* page 486, second line of the Assay, beginning with the words 'add 10 mils,' modifying the process there given by increasing the ammonia water to 5 mils which, with about 5 mils of distilled water, is to be used in divided portions to rinse out the dish in which the mixture was evaporated; before titrating treat the residue twice with 5 mils of ether, evaporating to dryness each time." *U. S.*

"Evaporate 100 millilitres in an evaporating basin on a water-bath until it measures about 10 millilitres, add, if necessary, sufficient *alcohol* (90 per cent.) to dissolve any separated substance and transfer to a separator, rinsing the dish with a little *water.* Add 10 millilitres of *water,* 20 millilitres of *chloroform,* and 2 millilitres of *solution of ammonia.* Shake well and separate the chloroformic layer. Repeat the extraction with two successive portions of 10 millilitres of *chloroform.* Mix the chloroformic solutions, and shake them with 10 millilitres of *N/1 solution of sulphuric acid* diluted with twice its volume of *water.* Separate the chloroformic solution. Repeat the shaking with a further 10 millilitres of the acidified water. Mix the acid solutions, add 20 millilitres of *chloroform* and 4 millilitres of *solution of ammonia.* Shake well, draw off the chloroformic solution into a beaker, and repeat the extraction with two further portions, each of 10 millilitres, of *chloroform.* Allow the mixed chloroformic solutions to evaporate, dry the residue on a water-bath for thirty minutes, dissolve it in 10 millilitres of *N/20 solution of sulphuric acid* and titrate with *N/20 solution of sodium hydroxide,* using *tincture of cochineal* as indicator. Deduct the number of millilitres of alkaline solution required from 10, and multiply the difference by 0.01446; the product will be the weight in grammes of the alkaloids contained in 100 millilitres of the tincture. This quantity should be not less than 0.035 gramme. Should the tincture contain more than this proportion it must be diluted with the necessary quantity of Alcohol (70 per cent.).

"Examined by the foregoing process, Tincture of Belladonna is found to contain in 100 millilitres 0.035 gramme of the alkaloids of Belladonna Leaves. *Limit of error* 0.002 gramme in excess or defect. This Tincture contains seven-tenths of the proportion of alkaloids contained in the Tincture of Belladonna of the British Pharmacopœia, 1898. It may be used when the Tinctura Belladonnæ of the International Agreement is required." *Br.*

In the U. S. P., 1890, the name of this tincture was changed to *Tinctura Belladonnæ Foliorum,* for the sake of greater precision. In the U. S. P. VIII its strength was reduced to 10 per cent. to conform to the International Protocol standard.

The tincture is an efficient preparation when made from the recently dried leaves and assayed by the official process.

Dose, from five to fifteen minims (0.3–0.9 mil).

TINCTURA BENZOINI. U. S.

TINCTURE OF BENZOIN Tr. Benz.

(tĭnc-tū'rą bĕn-zo-ī'nī)

Teinture (alcoolé) de Benjoin, *Fr. Cod.;* Tinctura Benzoës, *P. G.;* Benzoëtinktur, *G.;* Tintura di benzoino, *It.;* Tintura alcoholica de benjui, *Sp.*

* "Benzoin, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using alcohol as the solvent." *U. S.*

This tincture was introduced into the Pharmacopœia chiefly for the purpose of adding to ointments to prevent rancidity. This, however, is bad pharmaceutical practice and is hardly ever followed.

Dose, fifteen to thirty minims (0.9–1.8 mils).

TINCTURA BENZOINI COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF BENZOIN Tr. Benz. Co.

(tĭnc-tū'rą bĕn-zo-ĭ'nī cŏm-pŏs'ĭ-tą)

Tinctura Balsamica, Balsamum Commendatoris, Elixir Traumaticum; Friars' Balsam; Teinture (alcoolé) balsamique, *Fr. Cod.;* Baume du Commandeur de Permes, *Fr.;* Persischer Wundbalsam, *G.*

* "Benzoin, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Aloes, in No. 40 powder, *twenty grammes* [or 308.6 grains]; Storax, *eighty grammes* [or 2 ounces av., 360 grains]; Balsam of Tolu, *forty grammes* [or 1 ounce av., 180 grains]; to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using alcohol as the solvent." *U. S.*

"Benzoin, in powder, 100 *grammes;* Prepared Storax, 75 *grammes;* Balsam of Tolu, 25 *grammes;* Aloes, 20 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.*

"Macerate the Benzoin, Storax, Balsam of Tolu, and Aloes with eight hundred millilitres of the Alcohol in a closed vessel for two days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

Compound tincture of benzoin now contains 10 Gm. of benzoin to each 100 mils instead of 12 as in the U. S. P., 1890.

Uses.—Compound tincture of benzoin is chiefly employed both for its antiseptic and protective effect as a local application to minor *wounds, chapped hands* or *nipples, indolent ulcers,* etc. It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume du commandeur, Wade's balsam, Balsam de Maltha, Friar's balsam, Jesuit's drops, Turlington's balsam,* etc., which were formerly in great repute, and are still esteemed by the people, as pectorals and vulneraries. The compound tincture of benzoin is precipitated by water. A variety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin.

It is occasionally employed internally as a stimulating expectorant in *chronic bronchitis.* More frequently it is used as an inhalant by adding a teaspoonful of the tincture to a pint of hot water and breathing the vapors; this mode of treatment is especially useful in the early stages of *acute bronchitis.* It has also been recommended in *chronic dysentery* with the idea that it would exercise its local action upon the ulcerated surface of the colon, but is of doubtful utility.

Dose, fifteen to sixty minims (0,9–3.75 mils).

TINCTURA BERBERIDIS. Br.

TINCTURE OF BERBERIS

(tĭnc-tū'rą bęr-bĕr'ĭ-dĭs)

"Berberis, in No. 60 powder, 100 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.*

"Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.* This tincture is used as a bitter tonic.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA BUCHU. Br.

TINCTURE OF BUCHU

(tĭnc-tū'rą bū'ċhū)

Teinture (alcoolé) de Buchu, *Fr. Cod.;* Teinture de Bucco, *Fr.;* Buchutinktur, *G.*

"Buchu Leaves, in No. 20 powder, 200 *grammes;* Alcohol (60 per cent.) sufficient to produce, 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has the virtues of buchu leaves.

Dose, from one to two fluidrachms (3.75–7.5 mils), either simply diluted with water or as an addition to the infusion of the leaves.

TINCTURA CALUMBÆ. U. S., Br.

TINCTURE OF CALUMBA Tr. Calumb.

(tĭnc-tū'rą cą-lŭm'bæ)

Tinctura Colombo; Teinture (alcoolé) de Colombo, *Fr. Cod.;* Kolombotinktur, *G.;* Tintura alcoholica de colombo, *Sp.*

* "Calumba, in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), packing the moistened drug moderately, and using a mixture of *three volumes* of alcohol and *two volumes* of water as the menstruum." *U. S.*

"Calumba Root, in No. 20 powder, 100 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture was doubled in strength at the U. S. P. (VIII) in order to bring it into the class of 20 per cent. non-potent tinctures. The British tincture 1914 retains the strength of 10 Gm. of drug in each 100 mils.

Joseph Ince recommends that the tincture be prepared from the root as found in commerce, without further slicing or powdering it. Made as he proposes, the tincture is clear and bright; while if the powdered root is used it will be very turbid, even after filtration. (*P. J.,* xiv, 491.) No. 20 powder is now directed instead of the No. 50 powder used in older Pharmacopœias. Tincture of calumba may be added to tonic infusions or decoctions, to increase their stimulant power, but, like all the other bitter tinctures, should be used with caution.

Dose, of the U. S. tincture one-half to one fluidrachm (1.8–3.75 mils), of the Br. tincture one to two fluidrachms (3.75–7.5 mils).

TINCTURA CANNABIS. U. S. (Br.)

TINCTURE OF CANNABIS Tr. Cannab. [Tinctura Cannabis Indicæ, U.S.P. VIII]

(tĭnc-tū'rą căn'ną-bĭs)

"When assayed biologically Tincture of Cannabis produces incoördination when administered to dogs in a dose of not more than 0.3 mil per kilogramme of body weight." *U. S.*

Tinctura Cannabis Indicæ, *Br.*; Tincture of Indian Hemp; Tincture of Hemp; Teinture (alcoolé) de Chanvre de l'Inde, *Fr. Cod.*; Indischhanftinktur, *G.*

* "Cannabis, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using alcohol as the menstruum, and adjusting the volume of the finished Tincture to conform with the above biological standard." *U. S.*

"Extract of Indian Hemp, 50 *grammes;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve." *Br.*

"Assay.—Proceed as directed under Biological Assays (Part III)." *U. S.* (Also see *Cannabis*, p. 279).

Tincture of cannabis is assayed by tests upon dogs and it is generally advisable, for this purpose, to concentrate the tincture to about one-fourth its bulk. Care should be observed in the process of evaporation that the temperature does not rise above 60° C. (140° F.).

The American reader must take care not to confound the Indian Hemp here referred to with *Apocynum cannabinum*, known by the same name in this country. The term "Indian Hemp" should be dropped entirely, as its continued use has been the cause of at least one fatal mistake. The strength of the present tincture is about 33 per cent. less than that of the 1890 tincture.

Dose, ten to thirty minims (0.6–1.8 mils), to be gradually increased until some effects are experienced.

Off. Prep.—Tinctura Chloroformi et Morphinæ Composita, *Br.* Mistura Chloroformi et Morphinæ Composita. *N. F.*

TINCTURA CANTHARIDIS. U. S. (Br.)

TINCTURE OF CANTHARIDES Tr. Canthar. [Cantharidis tinctura P.I.]

(tĭnc-tū'rą cąn'thăr'ĭ-dĭs)

Tinctura Cantharidini, *Br*; Tincture of Cantharidin; Tincture of Spanish Flies; Teinture (alcoolé) de Cantharide, *Fr. Cod.*; Tinctura Cantharidum, *P. G.*; Spanischfliegentinktur, *G.*; Tinctura di cantaridi, *It.*; Tinctura alcoholica de cantaridas, *Sp.*

* "Cantharides, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Place the cantharides in a strong tin container, which has a capacity of not less than *two thousand mils* [or 67 fluidounces, 301 minims]. Add *one thousand mils* of alcohol, agitate the mixture thoroughly, and insert in the opening of the can a tightly fitting cork through which passes a glass tube, not less than 6.4 mm. in diameter and 75 cm. in length. Place the can in a water bath and maintain a temperature of from 50° to 55° C. (122°–131° F.) for twenty-four hours with frequent agitation. Then remove it from the water bath, pour the contents into a cylindrical percolator, in the neck of which has been placed a pledget of purified cotton, allow the percolation to proceed, and, after the liquid has disappeared from the surface and ceased to drop from the percolator, gradually pour on sufficient alcohol to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Cantharidin, 0.1 *gramme;* Chloroform, 10.0 *millilitres;* Alcohol (90 per cent.) sufficient to produce, 1000.0 *millilitres.* Dissolve the Cantharidin in the Chloroform, and add sufficient of the Alcohol to produce the required volume. This tincture contains approximately one-seventh of the proportion of Cantharidin contained in the Tinctura Cantharidis of the International Agreement; it contains approximately the same proportion of Cantharidin as the Tinctura Cantharidis of the British Pharmacopœia, 1898." *Br.*

An improvement was made in this tincture in the 1880 revision by substituting alcohol for diluted alcohol. It is frequently used in mixtures of castor oil and alcohol in the so-called hair tonics, and when made with diluted alcohol turbidity results. The official tincture is double the strength of that of the U. S. P. 1890 and is now in conformity with the provisions of the International Protocol. It is the most convenient form for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis.*) If made with diluted alcohol, when long kept it deposits fatty matter, cantharidin in rhomboidal tables, and other crystals of a quite different form. It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration. The British tincture, 1914, is made by dissolving the blistering principle, cantharidin, in chloroform and alcohol. It is about the strength of the tincture of the Br. Pharm., 1898.

Dose, of the U. S. tincture, one to three minims (0.06–0.2 mil); of the Br., two to five minims (0.12–0.3 mil).

TINCTURA CAPSICI. U. S., Br.

TINCTURE OF CAPSICUM Tr. Capsic.

(tĭnc-tū'rą căp'sĭ-cī)

Tincture of Cayenne Pepper; Teinture (alcoolé) de Piment des Jardins, *Fr.*; Tinctura capsici, *P. G.*; Spanischpfeffertinktur, *G.*

* "Capsicum, in No. 50 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *ninety-five volumes* of alcohol and *five volumes* of water as the menstruum." *U. S.* "Capsicum, in No. 20 powder, 50 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

The U. S. P. tincture is double the strength of the British. The alcoholic strength of the menstruum is of unusual proportions, 19 volumes of alcohol to 1 volume of water, the reason for this is that, on account of oleoresinous constituents of capsicum, alcohol is required and on account of a small quantity of a constituent

soluble in water and insoluble in alcohol a little water must be added to the menstruum to prevent cloudiness. It is used in atonic conditions of the stomach, especially in *alcoholic gastritis.* It may also be used locally in various sluggish conditions of the throat and for the various purposes for which red pepper is applicable. (See *Capsicum.*) Applied by means of camel's-hair pencil to the *relaxed uvula,* it sometimes produces contraction and relieves prolapsus of that part.

Dose, of the U. S. tincture, five to ten minims (0.3–0.6 mil); of the Br. preparation, ten to twenty minims (0.6–1.3 mils).

Off. Prep.—Tinctura Chloroformi et Morphinæ Composita, *Br.;* Mistura Chloroformi et Morphinæ Composita, *N. F.;* Mistura Opii et Chloroformi Composita, *N. F.;* Mistura Opii et Rhei Composita, *N. F.*

TINCTURA CARDAMOMI. U. S.

TINCTURE OF CARDAMOM Tr. Cardam.

(tĭnc-tū'rą cär-dą-mō'mī)

Teinture (alcoolé) de Cardamome, *Fr.;* Kardamomentinktur, *G.*

* "Cardamom Seed, in No. 40 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains], to make *onè thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using diluted alcohol as the menstruum." *U. S.*

The strength of this tincture was doubled in the U. S. P. (VIII) in order to bring it into the 20 per cent. class; it is an agreeable but strong aromatic, and may be advantageously added to tonic and purgative infusions.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA CARDAMOMI COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF CARDAMOM Tr. Cardam. Co.

(tĭnc-tū'rą cär-dą-mō'mī cǫm-pŏş'ĭ-tą)

Teinture de Cardamome composée, *Fr.;* Zusammengesetzte Kardamomentinktur, *G.*

* "Cardamom Seed, in No. 40 powder, *twenty grammes* [or 308.6 grains]; Saigon Cinnamon, in No. 60 powder, *twenty-five grammes* [or 386 grains]; Caraway, in No. 40 powder, *twelve grammes* [or 185 grains]; Cochineal, in No. 60 powder, *five grammes* [or 77 grains]. To make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), macerating the mixed powders in *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] of a mixture of *fifty mils* [or 1 fluidounce, 331 minims] of glycerin and *nine hundred and fifty mils* [or 32 fluidounces, 59 minims] of diluted alcohol and completing the preparation by using first the remainder of the mixture prepared as directed above and then diluted alcohol." *U. S.* "Cardamom Seeds, in No. 20 powder, 14 *grammes;* Caraway Fruit, in No. 20 powder, 14 *grammes;* Cinnamon Bark, in No. 20 powder, 28 *grammes;* Cochineal, in No. 20 powder, 7 *grammes;* Glycerin, 100 *millilitres;* Alcohol (45 per cent.) sufficient to produce 1000 *millilitres.* Moisten the mixed powders with fifty millilitres of the Alcohol, and prepare, by the *percolation process,* eight hundred and fifty *millilitres* of tincture. Add the Glycerin and sufficient of the Alcohol to produce the required volume." *Br.*

In this tincture and the one immediately preceding, the proportion of cardamom seems to be reduced, but official cardamom seed now means the seed recently removed from the capsules.

This is a very agreeable aromatic tincture, occasionally used as a carminative, but more frequently as an addition to mixtures, infusions, etc., which it renders pleasant to the taste and acceptable to the stomach. It is one of the most highly prized vehicles, not merely because of its pleasant flavor, but also on account of its beautiful color. The substitution of glycerin in the U. S. formula of 1880 for the honey formerly used was an improvement, as it increases the stability of the preparation.

Dose, one to two fluidrachms (3.75–7.5 mils).

TINCTURA CASCARILLÆ. Br.

TINCTURE OF CASCARILLA

(tĭnc-tū'rą căs-cą-rĭl'læ)

Teinture (alcoolé) de Cascarille, *Fr. Cod.;* Kaskarilltinktur, *G.*

"Cascarilla, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.) sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred and fifty *millilitres* of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has the properties of cascarilla, but is seldom, if ever, used in this country.

Dose, from thirty minims to two fluidrachms (1.8–7.5 mils).

TINCTURA CHIRATÆ. Br.

TINCTURE OF CHIRETTA

(tĭnc-tū'rą ċhĭ-rā'tæ)

Tincture of Chirata; Teinture (alcoolé) de Chirette, *Fr.;* Chirettatinktur, *G.*

"Chiretta, in No. 40 powder, 100 *grammes;* Alcohol (60 per cent.) sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is used as a bitter tonic. Although no longer recognized by the U. S. P., it is still prescribed in this country. The tincture of the U. S. 1890 was of twenty per cent. strength.

Dose, from one to two fluidrachms (3.75–7.5 mils), three or four times a day.

TINCTURA CHLOROFORMI ET MORPHINÆ COMPOSITA. Br.

COMPOUND TINCTURE OF CHLOROFORM AND MORPHINE

(tĭnc-tū'rą ¢hlō-rǫ-fōr'mī ĕt mör-phī'næ cǫm-pŏs'ĭ-tą)

"Chloroform, 75 *millilitres;* Morphine Hydrochloride, 10 *grammes;* Diluted Hydrocyanic Acid, 50 *millilitres;* Tincture of Capsicum, 25 *millilitres;* Tincture of Indian Hemp, 100 *millilitres;* Oil of Peppermint, 2 *millilitres;* Glycerin, 250 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Mix the Chloroform, Tincture of Capsicum, Tincture of Indian Hemp, Oil of Peppermint, and Glycerin, with four hundred and fifty *millilitres* of the Alcohol, and dissolve the Morphine Hydrochloride in the mixture; add the Diluted Hydrocyanic Acid, and sufficient of the Alcohol to produce the required volume. This Compound Tincture contains in 1 millilitre 7.5 centimils of Chloroform, 1 centigram of Morphine Hyrochloride, and 5 centimils of Diluted Hydrocyanic Acid; it contains in 10 minims ¾ minim of Chloroform, ⅓ grain of Morphine Hydrochloride, and ½ minim of Diluted Hydrocyanic Acid." *Br.*

This is the official substitute for *chlorodyne,* the well-known British nostrum. It does not differ from the process of the Br. Pharm. 1898, except that the oil of peppermint was increased from 1.5 mils to 2 mils. It is much stronger than the *Mistura Opii et Chloroformi Composita* of the N. F. IV (see Part III).

Dose, from five to fifteen minims (0.3–0.9 mil).

TINCTURA CINCHONÆ. U. S., Br.

TINCTURE OF CINCHONA Tr. Cinch.

(tĭnc-tū'rą cĭn-¢hō'næ)

"One hundred mils of Tincture of Cinchona yields not less than 0.8 Gm. nor more than 1 Gm. of the alkaloids of cinchona." *U. S.* "Tincture of Cinchona contains in 100 millilitres 1 gramme of the alkaloids of Red Cinchona Bark." *Br.*

Tinctura Cinchonæ Flavæ; Tincture of Yellow Cinchona; Tincture of Peruvian Bark; Teinture (alcoolé) de Quinquina jaune, *Fr. Cod.;* Tinctura Chinæ, *P. G.;* Chinatinktur, *G.;* Tintura di china, *It.*

* "Cinchona, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using as the first menstruum a mixture of *seventy-five mils* [or 2 fluidounces, 257 minims] of glycerin, *six hundred and seventy-five mils* [or 22 fluidounces, 396 minims] of alcohol, and *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of water and completing the percolation with a mixture of *two volumes* of alcohol and *one volume* of water. Then adjust the volume of the finished Tincture so that each *one hundred mils* contains 0.9 Gm. of the alkaloids of cinchona." *U. S.*

"Red Cinchona Bark, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with two hundred *millilitres* of the Alcohol; set aside for seven days in a closed vessel; percolate with more of the Alcohol, until seven hundred *millilitres* of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter.

"Take ten millilitres of the strong tincture so prepared, and determine the proportion of alkaloids contained in it by the process described under 'Extractum Cinchonæ Liquidum.' Add to the bulk of the strong tincture such a quantity of the Alcohol that 100 millilitres of the resulting Tincture contain 1 gramme of the alkaloids of Red Cinchona Bark. Examined by the process described under 'Extractum Cinchonæ Liquidum' Tincture of Cinchona is found to contain in 100 millilitres 1 gramme of the alkaloids of Red Cinchona Bark. *Limit of error* 0.05 gramme in excess or defect." *Br.*

Assay.—"Evaporate 25 mils of Tincture of Cinchona on a water bath until it measures about 15 mils, add 10 Gm. of purified sawdust (see Reagents, Part III), incorporate this thoroughly and then continue the evaporation at a temperature not exceeding 80° C. (176° F.) until it is dry. Transfer the impregnated sawdust to a 500 mil flask, and proceed as directed in the assay under *Cinchona,* page 350, fourth line of the Assay, modifying the process there given by increasing the ammonia water to 10 mils and using this in divided portions to rinse the dish in which the mixture was evaporated; then add the rinsings to the flask." *U. S.*

This tincture is very properly made with a large proportion of bark, as in the bitter tinctures it is important that the alcohol should bear as small a proportion to the tonic principle as possible. Even when strongest, however, it cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. The tincture of the Br. Pharm. 1898 and 1914 is now made from 70 per cent. alcohol instead of the old menstruum 50 per cent., and is assayed so that it has a definite strength (100 mils containing 1 Gm. of alkaloids); these are undoubted improvements. A deposit is apt to form in the tincture when kept, consisting chiefly of cinchonic red holding probably a portion of the alkaloids in combination. This was found by J. Adams to be perfectly dissolved by heat, though it uniformly reappeared on the cooling of the tincture. The addition of diluted sulphuric acid did not cause its solution, and, even though it was removed by filtering the tincture, the deposition was afterwards renewed. (*P. J.,* April, 1868, 470.) In reference to a mode of obviating in some measure this tendency to deposition, the reader is referred to the statements of M. Vauflart on the subject of deposition in the tinctures prepared by percolation. A. B. Taylor, in experimenting on this subject, prepared a tincture in which the menstruum consisted of two parts of alcohol, one part of water,

and one part of glycerin, and which was kept three months without undergoing deposition. (*A. J. P.*, Jan. 1865, 50.) This suggested the addition of glycerin to the official formula, and there can be no doubt that the tincture has been thereby improved, experience having demonstrated the utility of glycerin in liquid preparations of cinchona. Tincture of cinchona is rarely employed, but may be used as a tonic.

Dose, from one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Tinctura Cinchonæ Composita, *Br.*

TINCTURA CINCHONÆ COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF CINCHONA Tr. Cinch. Co.

(tĭnc-tū'rą cĭn-ȼhō'næ cǫm-pŏs'ı̣-tą)

"*One hundred mils* of Compound Tincture of Cinchona yields not less than 0.4 Gm. nor more than 0.5 Gm. of the alkaloids of cinchona." *U. S.* "Compound Tincture of Cinchona contains in 100 millilitres 0.5 gramme of the alkaloids of Red Cinchona Bark." *Br.*

Compound Tincture of Peruvian Bark; Huxham's Tincture of Bark; Teinture de Quinquina composée, Elixir fébrifuge d'Huxam, *Fr.*; Tinctura Chinæ Composita, *P. G.*; Zusammengesetzte Chinatinktur, *G.*

* "Red Cinchona, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Bitter Orange Peel, in No. 40 powder, *eighty grammes* [or 2 ounces av., 360 grains]; Serpentaria, in No. 60 powder, *twenty grammes* [or 308.6 grains], to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using as the first menstruum a mixture of *seventy-five mils* [or 2 fluidounces, 257 minims] of glycerin, *six hundred and seventy-five mils* [or 22 fluidounces, 396 minims] of alcohol and *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of water and completing the percolation with a mixture of *two volumes* of alcohol and *one volume* of water. Then adjust the volume of the finished Tincture so that each *one hundred mils* contains 0.45 Gm. of the alkaloids of cinchona." *U. S.*

"**Assay.**—Proceed as directed in the assay under *Tinctura Cinchonæ,* page 1136, modifying the process there given by using 50 mils of the Compound Tincture instead of 25 mils of the tincture there directed." *U. S.*

"Dried Bitter-Orange Peel, bruised, 50 *grammes;* Serpentary Rhizome, in No. 40 powder, 25 *grammes;* Cochineal, in powder, 3 *grammes;* Tincture of Cinchona, 500 *millilitres;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Mix the solid ingredients with five hundred millilitres of the Alcohol; set aside in a closed vessel for seven days, shaking frequently; strain, and then press; mix the two liquids thus obtained; add the Tincture of Cinchona, and sufficient of the Alcohol to produce the required volume; set aside for twenty-four hours; filter. Examined by the process described under 'Extractum Cinchonæ Liquidum' Compound Tincture of Cinchona is found to contain in 100 millilitres 0.5 gramme of the alkaloids of Red Cinchona Bark. *Limit of error* 0.05 gramme in excess or defect." *Br.*

This is the preparation commonly known by the name of *Huxham's tincture of bark.* It differs from that official in the U. S. P., 1890, only in the alcoholic strength of the menstruum, which is now about in the proportion of 2.7 volumes of alcohol to 1 volume of water; it was formerly 3 volumes of alcohol to 1 volume of water. The use of glycerin is an improvement, precipitation being thus largely prevented. In the U. S. P. VIII the drugs are not directed in the powdered state, the intention being to mix the drugs together and then to reduce the mixture to a *uniform* powder; in this way the volatile principles in the Serpentaria and Orange Peel are retained, and thorough exhaustion by percolation is secured. In the U. S. P. IX this principle was omitted probably on account of the difficulty of its execution. The process for the British tincture (1898) presents some novel features. Half of the quantity of the tincture is first made from four of the ingredients; this is then mixed with an equal bulk of tincture of cinchona. The reason for this was probably to avoid assaying a mixed product during the process; but the final test has to deal with the finished tincture, and the utility of the whole method is doubtful. Compound tincture of cinchona is an excellent bitter tonic, useful for its local effect on the stomach but too feeble in the principles of cinchona to serve when the systemic action of the drug is required.

Dose, one to two fluidrachms (3.75–7.5 mils).

Off Prep.—Gargarisma Guaiaci Composita, *N. F.*

TINCTURA CINNAMOMI. U. S., Br.

TINCTURE OF CINNAMON Tr. Cinnam.

(tĭnc-tū'rą cĭn-ną-mō'mī)

Teinture (alcoolé) de Cannelle, *Fr. Cod.*; Tinctura Cinnamomi, *P. G.*; Zimmttinktur, *G.*; Tinctura alcoholica de canela, *Sp.*

* "Saigon Cinnamon, in No. 50 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *seventy-five volumes* of glycerin, *six hundred and seventy-five volumes* of alcohol, and *two hundred and fifty volumes* of water as the menstruum." *U. S.*

"Cinnamon Bark, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The British and the U. S. tinctures are now of the same strength. This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures and astringent infusions or decoctions.

By long keeping it is prone to gelatinize and become unfit for use. According to Greenish, this can be prevented by using a menstruum composed of six parts of alcohol and two parts of water. (*P. J.*, Feb. 1872, 641). Glycerin is now used in the menstruum for this purpose. It is an agreeable flavoring to other tinctures and because of its astringent powers is especially used in *diarrhea* mixtures.

Dose, one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Elixir Taraxaci Compositum, *N. F.;* Mistura Rhei Alkalina, *N. F.*

TINCTURA COCCI. Br.

TINCTURE OF COCHINEAL

(tĭnc-tū'rą cŏc'cī)

Teinture (alcoolé) de Cochenille, *Fr. Cod.;* Cochenilletinktur, *G.*

"Cochineal, in powder, 100 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This is valued chiefly for imparting color to liquid preparations; four or five per cent. of this tincture will give a deep red color. (See *Coccus.*)

Dose, from twenty minims to a fluidrachm (1.3–3.75 mils).

TINCTURA COLCHICI SEMINIS. U. S. (Br.)

TINCTURE OF COLCHICUM SEED Tr. Colch. Sem.

[Colchici tinctura P. I.]

(tĭnc-tū'rą cŏl'çhį-cī sĕm'į-nīs)

"*One hundred mils* of Tincture of Colchicum Seed yields not less than 0.036 Gm. nor more than 0.044 Gm. of colchicine." *U. S.*

Tinctura Colchici, *Br.;* Tincture of Colchicum; Tinctura Colchici, *U. S.* 1890; Teinture (alcoolé) de semence de Colchique, *Fr. Cod.;* Tinctura Colchici, *P. G.;* Zeitlosentinktur, *G.;* Tintura alcoholica de colquico, *Sp.*

* "Colchicum Seed, in No. 50 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using a mixture of *three volumes* of alcohol and *two volumes* of water as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.04 Gm. of colchicine." *U. S.*

"Colchicum Seeds, in No. 30 powder, 100 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.* This Tincture is of approximately the same strength as the Tinctura Colchici of the International Agreement, and is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

Assay.—"Evaporate 150 mils of Tincture of Colchicum Seed on a water bath to about 20 mils, transfer it to a 50 mil graduated flask and rinse the evaporating dish with about 10 mils of distilled water, in divided portions. Then add 10 mils of solution of lead subacetate, shake the mixture thoroughly, add enough distilled water to make 50 mils and pour this into a 500 mil flask. Now add 250 mils of recently boiled distilled water, using part of the water to rinse the 50 mil flask, and proceed as directed in the assay under *Colchici Semen,* page 371, twelfth line of the Assay, beginning with the words 'filter off 200 mils.'" *U. S.*

The strength of this tincture was lowered to 10 Gm. per 100 mils in the U. S. P. VIII and IX to comply with the rule adopted for potent tinctures. An assay process was also appended.

It was at one time supposed that the tincture was quite as effective made from the unbruised as from the bruised seeds, but the opinion has been shown to be erroneous. (*A. J. P.*, xxvi, 120.) See also a paper by N. Rosenwasser, *Ibid.*, 1877, 436. Subsequently L. I. Morris showed that if the whole seeds were *digested* with hot diluted alcohol they could be perfectly exhausted. (*A. J. P.*, 1881, p. 6.) Maisch recommended, as a convenient method of comminuting the seeds, to macerate them for two or three days in a portion of the menstruum, then to remove them and bruise them in a clean iron mortar, taking care that none of the menstruum or of the seeds should be wasted. (*A. J. P.*, xxviii, 514.)

This tincture possesses the properties of colchicum, and may be given whenever that medicine is indicated, but the fluidextract, containing less alcohol, is generally preferred.

Dose, from fifteen to thirty minims (0.9–1.8 mils), to be repeated with caution.

TINCTURA CUBEBÆ. Br.

TINCTURE OF CUBEBS

(tĭnc-tū'rą cū-bĕ'bæ)

Teinture (alcoolé) de Cubèbe, *Fr. Cod.;* Kubebentinktur, *G.*

"Cubebs, in No. 20 powder, 200 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The U. S. P. has not recognized this tincture for many years, but it is official in the N. F. (see Part III). While this tincture represents the therapeutic virtue of cubeb, it is an inelegant form of administering that drug.

Dose, one to two fluidrachms (3.75–7.5 mils).

TINCTURA DATURÆ SEMINUM. Br.

TINCTURE OF DATURA SEEDS

(tĭnc-tū'rą dă-tū'ræ sē'mĭ-nŭm)

"Datura Seeds, in No. 20 powder, 250 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the bruised Datura Seeds with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture well represents the activities of *datura*.

Dose, five to fifteen minims (0.3–0.9 mil).

TINCTURA DIGITALIS. U. S., Br.

TINCTURE OF DIGITALIS Tr. Digit.
[Digitalis tinctura P. I.]

(tĭnc-tū'rą dĭg-ĭ-tā'lĭs)

"If assayed biologically the minimum lethal dose should not be greater than 0.006 mil of the Tincture, or the equivalent in Tincture of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog." *U. S.*

Tincture of Foxglove; Teinture (alcoolé) de Digitale, *Fr. Cod.*; Tinctura Digitalis, *P. G.*; Fingerhuttinktur, *G.*; Tintura di digitale, *It.*; Tintura alcoholica de digital, *Sp.*

* "Digitalis, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

"**Assay.**—For a method of assaying Tincture of Digitalis, see Biological Assays (Part III)." *U. S.*

"Digitalis Leaves, in No. 20 powder, 100 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres*. Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process*. This Tincture is of approximately the same strength as the Tinctura Digitalis of the International Agreement, and is of four-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

For method of biological assay of this tincture, see *Digitalis*.

It seems well established that the tincture of digitalis deteriorates more rapidly than well-kept leaves. The rate of deterioration of the tincture is probably from 10 to 20 per cent. a year, although it may be higher under unfavorable conditions. There is much evidence that a tincture of digitalis made with 60 or 70 per cent. of alcohol retains its activity better than that made with more dilute spirit; hence the wisdom of increasing the strength of alcohol. According to Focke, light accelerates the change. For literature upon this subject, see Eberhardt and Eldred. (*J. A. Ph. A.*, 1914, iii, p. 38.)

Tincture of digitalis probably represents the crude drug better than any other official preparation. The beginning dose is ordinarily from five to fifteen minims (0.3–0.9 mil) three or four times a day, increased cautiously as circumstances demand. Very much larger single doses may be employed, thus as high as a fluidrachm may occasionally be given at a dose if not repeated.

It should be remembered that, as with most of the tinctures, one minim is equivalent to about two drops.

Dose, from five to thirty minims (0.3–1.8 mils).

TINCTURA ERGOTÆ AMMONIATA. Br.

AMMONIATED TINCTURE OF ERGOT

(tĭnc-tū'rą ęr'gŏ-tæ ąm-mō-nĭ-ā'tą)

Tinctura Secalis Cornuti Ammoniata; Teinture Ammoniacale de Seigle Ergoté, *Fr.*; Ammoniakalische Mutterkorntinktur, *G.*

"Ergot, in No. 20 powder, 250 *grammes;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres*. Mix the Solution of Ammonia with nine hundred millilitres of the Alcohol; moisten the powder with one hundred millilitres of this mixture, and percolate with the remainder; press the marc; mix the expressed liquid with the percolate; add sufficient of the Alcohol to produce the required volume; set aside for twenty-four hours; filter." *Br.*

This is a new official tincture of the Br. Ph., 1898; it differs from the tincture recommended by the British Pharmaceutical Conference in the use of solution of ammonia in place of aromatic spirit of ammonia.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA FERRI CHLORIDI. U. S. (Br.)

TINCTURE OF FERRIC CHLORIDE Tr. Ferr. Chlor.

(tĭnc-tū'rą fĕr'rī ęhlō'rĭ-dī)

"A hydro-alcoholic solution containing ferric chloride [$FeCl_3 = 162.22$] (about 13 per cent.), corresponding to not less than 4.48 per cent. of Fe. Protect Tincture of Ferric Chloride from light." *U. S.*

Tinctura Ferri Perchloridi, *Br.*; Tincture of Chloride of Iron; Tincture Ferri Muriatis; Tincture of Perchloride of Iron; Tincture of Muriate of Iron; Tinctura Ferri Sesquichloridi; Teinture de Perchlorure de fer, *Fr.*; Eisenchloridtinktur, *G.*

* "Solution of Ferric Chloride, *three hundred and fifty mils* [or 11 fluidounces, 401 minims]; Alcohol, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the solution with enough Alcohol to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], then transfer the Tincture to an amber-colored, glass-stoppered bottle and keep it for at least three months before dispensing." *U. S.*

"Strong Solution of Ferric Chloride, 250 *millilitres;* Alcohol (90 per cent.), 250 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres*. Mix." *Br.*

This tincture does not differ materially from that official in 1880, the change due to making one by weight and the other by volume, and the rounding of the figures, causing a difference in specific gravity—the U. S. P., 1880, tincture having the sp. gr. 0.980 and the U. S. P., 1890, tincture that of 0.960, the latter thus being slightly lighter. In the U. S. P. VIII the quantity of Solution of Ferric Chloride used in making 1000 mils of the tincture was increased from 250 mils to 350 mils on account of the reduction in strength of the solution from

13 per cent. of metallic iron to 10 per cent. This increases the specific gravity to about 1.00. The strength of the new tincture, in ferric chloride, remains practically the same as the 1890 preparation.

The U. S. formula of 1870 appeared, in respect to the precise method of proceeding, to be copied from that of E. R. Squibb, published in *A. J. P.* (1857, p. 290). Iron wire was chosen as the form of iron to be used, because it is generally the purest. This, which was in very slight excess, was first treated with a portion of the hydrochloric acid, which formed with it ferrous chloride, with the escape of hydrogen, producing effervescence. The action was allowed to go on spontaneously until effervescence ceased, and was then aided by heat, which caused the saturation of the acid used. The solution being filtered, the remainder of the hydrochloric acid was added, and afterwards the nitric acid gradually, the liquid having been heated to the boiling point before the latter addition. The nitric acid was decomposed, with the escape of nitrous fumes producing effervescence, while, through the influence of a portion of its oxygen and the additional portion of hydrochloric acid, the ferrous chloride was converted into ferric chloride, the conversion being completed when the effervescence ceased and the previous green color had been changed to a reddish-brown. The precise reactions by which these changes are effected have been explained elsewhere. (See *Ferri Chloridum*, page 464, and *Liquor Ferri Chloridi*, page 634.) In the revision of 1870 the process was divided into two parts, and a new preparation, *Liquor Ferri Chloridi*, introduced. When this is added to the alcohol, the latter reacts gradually with the acid, producing a small proportion of an ester which gives a peculiar flavor to the tincture and probably modifies in some degree its influence on the system. For this reason it is preferable to keep the tincture a year before dispensing, and the official direction is to keep it at least three months.

Properties.—Tincture of ferric chloride is officially described as "a bright, amber-colored liquid, having a slightly ethereal odor, a very astringent, styptic taste, and an acid reaction. Specific gravity: about 1.00 at 25° C. (77° F.). The Tincture yields a brownish-red precipitate with ammonia water, a blue precipitate with potassium ferrocyanide T.S., and a white precipitate, insoluble in nitric acid, with silver nitrate T.S. After the Tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferricyanide T.S. (presence of some *ferrous salt*, due to reduction). Add a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Tincture (1 in 10); the crystal does not become brown, nor is a brownish-black zone developed around it (*nitric acid*).

"**Assay.**—Evaporate to dryness in a porcelain dish on a water bath about 5 mils of Tincture of Ferric Chloride, accurately weighed in a tared weighing-bottle. Add 2 mils of hydrochloric acid and 5 mils of solution of hydrogen dioxide to the residue and again evaporate the mixture to dryness. Dissolve this residue in 25 mils of distilled water, transfer the solution to a 250 mil glass-stoppered flask, mix it with 3 mils of hydrochloric acid and about 1 Gm. of potassium iodide, and allow the mixture to stand for thirty minutes at a temperature of 40° C. (104° F.). Cool the solution, add 100 mils of distilled water and titrate the liberated iodine with tenth-normal sodium thiosulphate V.S. It shows not less than 4.48 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Tincture of Ferric Chloride corresponds to not less than 8 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

The tincture is decomposed by the alkalies, alkaline earths and their carbonates, astringent vegetable infusions, and mucilage of acacia, which produces with it a brown semi-transparent jelly. All these substances are, therefore, incompatible with it in prescriptions.

Bestucheff's tincture, which is much used in Europe, is simply a solution of ferric chloride in a mixture of one measure of ether and three measures of alcohol. (See *Tinctura Ferri Chloridi Etherea*, N. F. IV.)

Uses.—Tincture of chloride of iron has in the past been attributed with curative properties verging on the mystical. Thus it has been supposed to exercise a specific action in *erysipelas*, *diphtheria*, and other infectious diseases. Its value in these states, however, is, to say the least, questionable. In *Bright's disease* it has been used not only for its chalybeate effect but with the idea that its astringent action would lessen the quantity of albumin in the urine. As it is an active coagulant of albumin, however, it cannot exist in the blood and therefore can never reach the kidney unchanged; any beneficial effect which may follow its employment in diseases of the kidney is of the same nature as that which is produced by other preparations of iron, namely, an enrichment of the hemoglobin content of the blood. In *anemias* it acts as a chalybeate, but is inferior to many other salts of iron. In the first place a dose of fifteen minims represents only approximately 0.7 grain of iron. In the second place, because of its high astringency and local irritant effect it cannot be administered in large quantities without producing disturbances in the stomach. Locally it is valuable as an astringent in *hemorrhages* and passive congestions of the mucous membrane. Mixed with equal parts of glycerin and water it may be applied by means of a swab with benefit in various types of *pharyngitis*. Its use as a gargle is not to be recommended as its acidity makes it injurious to the teeth.

Dose, five to thirty minims (0.3–1.8 mils), which may be gradually increased.

Off. Prep.—Liquor Ferri et Ammonii Acetatis, *U. S.*

TINCTURA GAMBIR COMPOSITA. U. S. (Br.)

COMPOUND TINCTURE OF GAMBIR Tr. Gambir Co. [Compound Tincture of Pale Catechu To replace Tincture Catechu Composita, U. S. 1890, Compound Tincture of Catechu]

(tĭnc-tū′rą găm′bĭr cọm-pŏș′ĭ-tą)

Tinctura Catechu, *Br.;* Tincture of Catechu; Teinture (alcoolé) de Cachou, *Fr. Cod.;* Tinctura Catechu, *P. G.;* Katechutinktur, *G.*

* "Gambir, in No. 50 powder, *fifty grammes* [or 1 ounce av., 334 grains]; Saigon Cinnamon, in No. 50 powder, *twenty-five grammes* [or 386 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using diluted alcohol as the solvent." *U. S.*

"Catechu, in powder, 200 *grammes;* Cinnamon Bark, bruised, 50 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

The name of this tincture was changed at the 1880 revision, so that it more accurately indicated its composition than did its former name. In the U. S. P. (8th Rev.) the name was again changed to Tinctura Gambir Composita. This was due to the introduction of gambir in place of catechu (see *Gambir*). The present tincture is one-half the strength of the U. S. P., 1890, compound tincture of catechu. Cinnamon has been present in the tincture of catechu of former Pharmacopœias in the same relatively large proportion—2 parts of cinnamon to 3 parts of catechu—and this disproportion has been usually overlooked. The present tincture contains 2 parts of gambir to 1 part of cinnamon. The British tincture (1898) was increased to 20 per cent. in the proportion of catechu, and is now four times the strength of the U. S. tincture. This is a grateful astringent tincture, useful in all cases to which catechu is applicable and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in *diarrhea.* It may be given with sweetened water or some mucilaginous liquid, or in port wine when this is not contra-indicated. It sometimes gelatinizes when kept, and becomes unfit for use.

Dose, of the U. S. tincture of gambir, two to four fluidrachms (7.5–15.0 mils); of the British tincture of catechu, one-half to two fluidrachms (1.8–7.5 mils).

Off. Prep.—Tinctura Pectoralis, *N. F.*

TINCTURA GELSEMII. U. S., Br.

TINCTURE OF GELSEMIUM Tr. Gelsem.

(tĭnc-tū′rą ǧęl-sĕm′ĭ-ī)

Teinture (alcoolé) de Gelsemium, *F.;* Gelsemiumtinktur, *G.*

* "Gelsemium, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *sixty-five volumes* of alcohol and *thirty-five volumes* of water as the menstruum." *U. S.*

"Gelsemium Root, in No. 40 powder, 100 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has proven a valuable addition, and will be preferred to the fluidextract for internal administration, as it is safer, and can be used more satisfactorily in extemporaneous combination. The menstruum of the U. S. P., 1890, and VIII and IX processes is weaker than that formerly official, alcohol having been replaced by alcohol diluted with water in the proportion of 65 to 35. For Farr and Wright's method of estimating this tincture, see *C. D.,* 1892, 263.

Dose, from five to twenty minims (0.3–1.3 mils).

TINCTURA GENTIANÆ COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF GENTIAN Tr. Gentian. Co.

(tĭnc-tū′rą ǧĕn-tĭ-ā′næ cọm-pŏș′ĭ-tą)

Teinture (alcoolé) de Gentiane Composée, *Fr.;* Zusammengesetzte Enziantinktur, *G.*

* "Gentian, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Bitter Orange Peel, in No. 40 powder, *forty grammes* [or 1 ounce av., 180 grains]; Cardamom Seed, in No. 40 powder, *ten grammes* [or 154 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), packing it moderately and using as the first menstruum a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol and *four hundred mils* [or 13 fluidounces, 252 minims] of water and completing the percolation with diluted alcohol." *U. S.*

"Gentian Root, cut small and bruised, 100.0 *grammes;* Dried Bitter-Orange Peel, bruised, 37.5 *grammes;* Cardamom Seeds, in powder, 12.5 *grammes;* Alcohol (45 per cent.), 1000.0 *millilitres.* Prepare by the *maceration process.*" *Br.*

There has always been difficulty from precipitation in this tincture; glycerin has been added to the menstruum to overcome this annoyance, but it is only partially successful. This is an elegant bitter, much used in *dyspepsia,* and as an addition to tonic mixtures in debilitated states of the digestive organs. There is, however, much danger of its abuse by alcoholics, especially in chronic cases.

Dose, one to two fluidrachms (3.75–7.5 mils).

TINCTURA GUAIACI. U. S.

TINCTURE OF GUAIAC Tr. Guaiac.

(tĭnc-tū′rą guaĭ′ą-cī)

Tinctura Guajaci; Teinture (alcoolé) de Résine de Gayac, *Fr.;* Guajaktinktur, *G.*

* "Guaiac, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make

one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using alcohol as the solvent." *U. S.*

Although this tincture can be prepared by percolation if care and skill are used, maceration is doubtless preferable.

This tincture is given in *chronic rheumatism* and *gout,* in the dose of from one to three fluidrachms three or four times a day. As it is precipitated by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension, although it is almost impossible, without actual emulsification, to prevent the resinous material from separating and forming a coating on the inner surface of the bottle. Schär recommends tincture of guaiac as a reagent to detect the presence of ozonizing bodies. (*Ph. Rund.,* 1894, 254.)

Dose, one fluidrachm (3.75 mils) three times a day.

Off. Prep.—Mistura Guaiaci, *N. F.*

TINCTURA GUAIACI AMMONIATA. U. S., Br.

AMMONIATED TINCTURE OF GUAIAC Tr. Guaiac. Ammon.

(tĭnc-tū'rą guaĭ'ą-cī ąm-mō-nī-ā'tą)

Ammoniated Tincture of Guaiacum; Tinctura Guaiaci Composita; Teinture (alcoolé) de Gayac ammoniacale, *Fr.*; Ammoniakalische Guajaktinktur, *G.*

* "Guaiac, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using aromatic spirit of ammonia as the solvent." *U. S.*

"Guaiacum Resin, in powder, 200 *grammes;* Oil of Nutmeg, 3 *millilitres;* Oil of Lemon, 2 *millilitres;* Strong Solution of Ammonia, 75 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Mix the Strong Solution of Ammonia with seven hundred millilitres of the Alcohol; add the Guaiacum Resin; set aside in a closed vessel for forty-eight hours, shaking frequently; filter; dissolve the Oil of Lemon and Oil of Nutmeg in the filtrate, and pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The British Pharmacopœia, 1898, improved the process for this tincture by abandoning the distilled aromatic spirit of ammonia used as a menstruum by the former British authority and substituting alcohol containing solution of ammonia and volatile oils, the proportion of oil of lemon having been reduced 60 per cent.

This tincture is celebrated in the treatment of *chronic rheumatism,* and is frequently also used in *amenorrhea.* It is more stimulating, and is probably more effectual, than the preceding on account of the presence of the alkali. It is precipitated by water, and should be administered emulsified with gum, so that the guaiac may be held in suspension.

Dose, from one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Gargarisma Guaiaci Composita, *N. F.*

TINCTURA HAMAMELIDIS. Br.

TINCTURE OF HAMAMELIS

(tĭnc-tū'rą hăm-ą-mĕl'ĭ-dĭs)

Teinture (alcoolé) de Hamamélis, *Fr.*; Hamamelistinktur, *G.*; Tinctura alcoholica de hamamelis, *Sp.*

"Hamamelis Bark, in No. 20 powder, 100 *grammes;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

Dose, from thirty to sixty minims (1.8–3.75 mils).

TINCTURA HYDRASTIS. U. S., Br.

TINCTURE OF HYDRASTIS Tr. Hydrast. [Tincture of Golden Seal]

(tĭnc-tū'rą hȳ-drăs'tĭs)

"*One hundred mils* of Tincture of Hydrastis yields not less than 0.36 Gm. nor more than 0.44 Gm. of the ether-soluble alkaloids of hydrastis." *U. S.*

Teinture (alcoolé) de Hydrastis, *Fr.*; Hydrastistinktur, *G.*; Tintura alcoholica de hidrastis, *Sp.*

* "Hydrastis, in No. 60 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using a mixture of *two volumes* of alcohol and *one volume* of water as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.4 Gm. of the ether-soluble alkaloids of hydrastis." *U. S.*

"Assay.—Evaporate 50 mils of Tincture of Hydrastis on a water bath until it measures about 10 mils, transfer the evaporated liquid to a separator, and proceed as directed in the assay under *Fluidextractum Belladonnæ Radicis,* page 486, second line of the Assay, beginning with the words "add 10 mils," modifying the process there given by using the ammonia water with about 5 mils of distilled water, in divided portions, to rinse out the dish in which the Tincture was evaporated. Use only ether as the immiscible solvent throughout the assay and dry the residue at 100° C. (212° F.) to constant weight, instead of titrating it. The weight of the residue represents the amount of ether-soluble alkaloids in 50 mils of Tincture of Hydrastis." *U. S.*

"Liquid Extract of Hydrastis, 100 *millilitres;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Mix." *Br.*

The British tincture is half the strength of that of the U. S. P. IX.

This tincture is useful in combination with other tinctures, or as an addition to extem-

poraneous mixtures where the fluidextract would not be so eligible.

Dose, from one to two fluidrachms (3.75–7.5 mils).

TINCTURA HYOSCYAMI. U. S., Br.

TINCTURE OF HYOSCYAMUS Tr. Hyosc. [Tincture of Henbane Hyoscyami tinctura P. I.]

(tĭnc-tū'rą hȳ-ǫs-cȳ'ą-mī)

"*One hundred mils* of Tincture of Hyoscyamus yields not less than 0.0055 Gm. nor more than 0.0075 Gm. of the alkaloids of hyoscyamus." *U. S.*

Teinture (alcoolé) de Jusquiame, *Fr.*; Bilsenkrauttinktur, *G.*; Tintura alcoholica de beleno, *Sp.*

* "Hyoscyamus, in No. 60 powder *one hundred grammes* [or 3 ounces av., 231 grains], to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using diluted alcohol as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.0065 Gm. of the alkaloids of hyoscyamus." *U. S.*

"Assay.—Evaporate 250 mils of Tincture of Hyoscyamus on a water bath to about 10 mils, transfer the evaporated liquid to a separator, and proceed as directed in the assay under *Fluidextractum Belladonnæ Radicis,* page 486, second line of the Assay, beginning with the words "add 10 mils," modifying the process there given by increasing the ammonia water to 5 mils which, with 5 mils of distilled water, is to be used, in divided portions, to rinse the dish in which the Tincture was evaporated; before titrating treat the residue twice with 5 mils of ether, evaporating to dryness each time." *U. S.*

"Hyoscyamus Leaves, in No. 20 powder, 100 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The strength of the British tincture (1898) was slightly reduced (20 per cent.) in order to bring it into the class of tinctures having the maximum dose of a fluidrachm. The strength was also reduced in the U. S. P. VIII and IX from 15 to 10 Gm. per 100 mils, and an assay process appended. The Br. and U. S. tinctures are now of the same strength.

This tincture possesses the activities of hyoscyamus. When it purges, as it sometimes does, it may be united with a very small proportion of tincture of opium.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA IODI. U. S. (Br.)

TINCTURE OF IODINE Tr. Iodi.

(tĭnc-tū'rą ī-ō'dī)

"An alcoholic solution of iodine and potassium iodide. *One hundred mils* contains not less than 6.5 Gm. nor more than 7.5 Gm. of I (126.92) and not less than 4.5 Gm. nor more than 5.5 Gm. of KI (166.02)." *U. S.*

Tinctura Iodi Mitis, *Br.*; Weak Tincture of Iodine; Tinctura Iodi Fortis, *Br.*; Strong Tincture of Iodine; Tinctura Iodinii, *U. S.*, 1870; Teinture (alcoolé) d'iode, *Fr. Cod.*; Tinctura Jodi, *P. G.*; Jodtinktur, *G.*; Solucion alcoholica de yodo, *Sp.*

* "Iodine, *seventy grammes* [or 2 ounces av., 205 grains]; Potassium Iodide, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *fifty mils* [or 1 fluidounce, 331 minims]; Alcohol, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the potassium iodide in the distilled water contained in a bottle graduated to *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]; add the iodine and agitate the mixture until solution is effected. Then add sufficient alcohol to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Tincture, and mix thoroughly." *U. S.*

"Assay for Potassium Iodide.—Evaporate 10 mils of Tincture of Iodine in a tared porcelain dish on a water bath and gently heat the residue over a Bunsen flame to volatilize the iodine; it leaves a residue weighing not less than 0.45 Gm. nor more than 0.55 Gm., which corresponds to the identity tests under *Potassii Iodidum.*

"Assay for Iodine.—Mix 5 mils of the Tincture with 25 mils of distilled water and titrate the solution with tenth-normal sodium thiosulphate V.S.; it requires not less than 25.6 mils nor more than 29.6 mils of tenth-normal sodium thiosulphate V.S. for complete decoloration.

"Each mil of tenth-normal sodium thiosulphate V.S. corresponds to 0.012692 Gm. of I." *U. S.*

In the British Pharmacopœia 1914 an important change was made in the names of the liquid preparations of iodine. The name has been changed from Tinctura Iodi to Tinctura Iodi Mitis, but the strength remains the same. Liquor Iodi Fortis now becomes Tinctura Iodi Fortis. The strength has been slightly increased.

Weak Tincture of Iodine (*Br.*).

"Iodine, 25 *grammes;* Potassium Iodide, 25 *grammes;* Distilled Water, 25 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve the Potassium Iodide and Iodine in the Distilled Water; add sufficient of the Alcohol to produce the required volume." *Br.*

"10 millilitres of the Tincture, diluted with 20 millilitres of *water,* require for decolorisation not less than 19.2 or more than 19.8 millilitres of *N/10 solution of sodium thiosulphate.* This Weak Tincture contains 0.025 gramme of Iodine in each millilitre; 1 minim contains about 1/44 grain. It is not of the same strength as the Tinctura Iodi of the International Agreement. It contains the same proportion of Iodine as the Tinctura Iodi of the British Pharmacopœia, 1898." *Br.*

Strong Tincture of Iodine (*Br.*).

"Iodine, 100 *grammes;* Potassium Iodide, 60

grammes; Distilled Water, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve the Potassium Iodide and the Iodine in the Distilled Water; add sufficient of the Alcohol to produce the required volume." *Br.*

"Five millilitres of the Tincture, diluted with 20 millilitres of *water,* require for decolorisation not less than 38.4 or more than 39.6 millilitres of *N/10 solution of sodium thiosulphate.* This Strong Tincture contains 0.1 gramme of Iodine in each millilitre; 1 minim contains about 1/11 grain. It is of approximately the same strength as the Tinctura Iodi of the International Agreement. It contains approximately the same proportion of Iodine as the Liquor Iodi Fortis of the British Pharmacopœia, 1898. *Br.*

An important change was made in the formula of tincture of iodine in the U. S. P. VIII by the addition of about 5 per cent. of potassium iodide; this improvement not only permits the dilution of the tincture with water without precipitating the iodine, so that the tincture can now be administered internally, but it also particularly increases the stability of the tincture.

When tincture of iodine made as in previous pharmacopœias by solution of iodine (alone) in alcohol was allowed to stand subjected to varying conditions for two months, the loss in iodine was as high as 7 per cent.; on the other hand the loss in iodine with tincture containing 5 per cent. of potassium iodide was not appreciable in the same length of time under similar treatment. The addition of potassium iodide also causes the iodine to dissolve rapidly in the alcohol, and in the U. S. P. IX formula, a small amount of water aids solution. The compound solution of iodine made with water is retained, and is most suitable for internal administration. (See *Liquor Iodi Compositus.*) The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well-stoppered bottles, in order to prevent the evaporation of the alcohol. It should never be dispensed in cork-stoppered vials, because of the destructive action of the iodine on the cork; rubber or glass stoppers should be used.

L. F. Kebler (*J. Ind. & E. C.,* 1913, p. 484) reports the results of analyses of a number of samples collected in pharmacies in the District of Columbia in which the iodine content ranged from 1.97 Gm. to 9.26 Gm. in 100 mils and the potassium iodide content from 0.0 to 6.82 Gm. in 100 mils.

J. W. Mardin (*J. A. P. A.,* 1913, p. 1464) gives a method of determining the alcohol in this preparation by a series of factors based upon the alternations in sp. gr. produced respectively by potassium iodide and iodine and gives tables which may be consulted for the determination by this method.

Properties.—The tincture has a deep brown color. One grain of iodine is contained in about fifteen minims, or thirty drops. It is at present less used internally than it formerly was, in consequence of an impression that it is apt to irritate the stomach. Water decomposes the tincture when it contains no potassium iodide and it is supposed that when this is swallowed the iodine is precipitated upon the mucous membrane. Besides, the tincture undergoes a gradual change when long kept, owing, according to Guibourt, to a reaction between the alcohol and the iodine. A portion of the latter is supposed to take hydrogen from the former, producing hydriodic acid, which dissolves another portion of the iodine to form iodized hydriodic acid, while the place of the hydrogen in the alcohol is supplied by iodine, giving rise to ethyl iodide and similar products. The new products have an agreeable odor and are soluble in water; and consequently the tincture gradually loses by time the property of being precipitated on dilution. A. Göpel found the change to be so slow, when the tincture is kept in the dark and at a low temperature, that in three months a specimen thus treated had lost but one per cent. of iodine. Commaille confirmed the labors of the last-mentioned investigator. Subsequent experiments have, however, given results somewhat at variance with those of Guibourt. Carles found that after exposure in a transparent glass flask to diffuse daylight for ten months, the tincture contained only one-twelfth per cent. of hydriodic acid. He was also unable to find any of the ethyl iodide which, according to Guibourt, is formed simultaneously with the acid. (*P. J.,* 3d ser., v. 88.)

Uses.—Tincture of iodine is now employed almost exclusively for its local effects. It is a powerful local irritant acting somewhat slowly but with great persistence. If applied too freely it will produce an acute dermatitis with desquamation of the cuticle. It is a favorite remedy as a counter-irritant in inflammations of the joint, especially when of a more or less chronic type, thus it is widely employed in *sprains* after the stage of acute inflammation has subsided, in *chronic rheumatism, arthritis deformans, gout, chilblains, myalgias,* and the like. In *scrofulous glands* and chronic rheumatic conditions it is often applied with the idea of obtaining the local counter-irritant effect as well as the constitutional action of the iodine from absorption through the skin. While it is true that if evaporation is guarded against perceptible amounts of iodine may be absorbed, after the application of the tincture to the skin as ordinarily employed, the quantity taken up by the system is insignificant. The irritant action of tincture of iodine is also made use of for the obliteration of serous cavities, as in the radical cure of *hydrocele* or *ovarian dropsies.*

As pointed out on page 592, iodine is a powerful germicide and within the last few years the tincture of iodine has become a valuable addition to the surgeon's armamentarium against infections. It is used for the purpose of sterilizing the skin, before operation or for hypodermic injections, for disinfecting *wounds* and in infections of accessible mucous membranes as of the nose and throat. It is also employed as a local remedy in the treatment

of *erysipelas,* but its application requires some caution and it is better to surround the inflamed surface with a border of the tincture, embracing a portion of both the sound and diseased skin with the idea of preventing the progress of the inflammation, than to attempt a complete cure by covering the whole surface affected.

Under the title of *colorless tincture of iodine* (*Tinctura Iodi Decolorata*) various combinations manufactured from tincture of iodine have been prepared. These preparations are calculated to mislead practitioners, for they contain no free iodine and therefore have not the therapeutic virtues of the official tincture, but are variable mixtures consisting principally of ammonium iodide and various other compounds of iodine. (See *Tinctura Iodi Decolorata,* N. F. IV, Part III.)

The former German tincture contains in addition some ethyl iodide, triethyl-ammonium iodide, and traces of sodium iodide and sulphate. Luc has found the inhalation of the fumes from slightly warmed tinctures very useful in *coryza.*

Lugol's solution (*Liquor Iodi Compositus,* page 646) is a much preferable preparation for the internal administration of iodine. Debauque, an apothecary of Mons, has ascertained that tannic acid has the property of rendering iodine soluble in water, and states that an ounce of syrup of orange-peel in four or six ounces of water will form a clear solution with a quantity of tincture of iodine containing five or six grains of the medicine. (*J. P. C.,* 3e sér., xx, 34.)

Dose, one to five minims (0.06–0.3 mil).

TINCTURA JALAPÆ. Br.

TINCTURE OF JALAP

(tĭnc-tū′rą ją-lā′pæ)

Teinture (alcoolé) de Jalap, *Fr. Cod.;* Jalapentinktur, *G.*

"Jalap, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), *a sufficient quantity.* Moisten the powder with one hundred millilitres of the Alcohol; pack in a percolator; gradually add more of the Alcohol until six hundred millilitres of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter. Determine the amount of Jalap Resin present in ten millilitres of the strong tincture so prepared by the process described under 'Jalapæ Resina,' and dilute the remainder of the strong tincture with sufficient of the Alcohol to produce a Tincture of Jalap containing 1.5 grammes of the Resin in 100 millilitres. When 10 millilitres of the Tincture, concentrated by evaporation, are mixed with eight times their volume of *water,* the resin thus separated, washed with *water* and dried at a gentle heat, weighs not less than 0.145 or more than 0.155 gramme." *Br.*

This tincture is no longer official in the U. S. Pharmacopœia, but is in the N. F. IV (see Part III). The tincture of jalap of the U. S. P. 1870 was made by percolating six troy-ounces of powdered jalap with a mixture of two measures of alcohol and one of water, until two pints of tincture were obtained.

This tincture is now prepared on the basis of proportion of resin, not of crude drug, as formerly. It possesses the medicinal virtues of jalap, and is sometimes added to cathartic mixtures.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA JALAPÆ COMPOSITA. Br.

COMPOUND TINCTURE OF JALAP

(tĭnc-tū′rą ją-lā′pæ cŏm-pŏs′ĭ-tą)

"Jalap, in No. 40 powder, 80 *grammes;* Scammony Resin, in powder, 15 *grammes;* Turpeth, in No. 40 powder, 10 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the mixed powders with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is also official in the N. F. IV (see Part III). It is a harsh but active purgative, capable of producing serious effects if given in over-dose.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA KALADANÆ. Br.

TINCTURE OF KALADANA

(tĭnc-tū′rą kă-lą-dā′næ)

"Kaladana, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This is a new tincture of the British Pharmacopœia 1914. It is used as a cathartic in doses of one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA KINO. U. S., Br.

TINCTURE OF KINO Tr. Kino

(tĭnc-tū′rą kī-nō)

Teinture (alcoolé) de Kino, *Fr. Cod.;* Kinotinktur, *G.*

* "Kino, *one hundred grammes* [or 3 ounces av., 231 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Place the kino in a capacious flask and pour on it *five hundred mils* [or 16 fluidounces, 435 minims] of boiling water. Agitate the mixture thoroughly, then heat it on a water bath, containing boiling water, for one hour, shaking it frequently. Allow the liquid to cool, add enough recently boiled water to make the product measure *five hundred mils* [or 16 fluidounces, 435 minims] and then add *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol. Stopper the flask, set it aside in a cool place for twenty-four hours and then decant the mixture through cheese cloth. Preserve it in a cool and dark place, in small bottles, tightly corked." *U. S.*

"Kino, in powder, 100 *grammes;* Glycerin, 150 *millilitres;* Distilled Water, 250 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Mix the Glycerin and the Distilled Water; rub the Kino in a mortar with a sufficient quantity of the mixture to form a smooth paste, gradually adding the remainder of the mixture; transfer to a closed vessel; add five hundred millilitres of the Alcohol; set aside for twelve hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

Much inconvenience is caused by the tendency of this tincture to gelatinize and gradually lose its astringency. The present official formula is believed to furnish a tincture free from this objection. It is probable that different specimens of kino vary in their tendency to gelatinize. Groves states that fresh kino will not gelatinize, and Martindale that the Australian kino is much more prone to do so than the East India drug. The air has some effect, for if this be entirely excluded the tincture will keep for a long time without undergoing the change. It should be introduced, when prepared, into very small bottles, which should be kept well corked and be opened only when wanted for use. J. D. Wood obtains a handsome preparation, which he believes to keep well and not gelatinize, by using a menstruum of 2 parts of alcohol sp. gr. 0.835, and 1 part each of water and glycerin.

L. Meyers Connor gets rid of the gelatinizing property by using magnesium carbonate in making the tincture, but it is very probable that a large part of the kino-tannic acid is removed at the same time. (*A. J. P.,* xlv, 260.) P. F. Smith of Louisville, furnished the following formula: "Take of Kino *one ounce and a half;* Ground Logwood *half an ounce;* Diluted Alcohol *a sufficient quantity.* Moisten the Logwood with a portion of the Diluted Alcohol, and introduce it into a displacement apparatus. Dissolve the Kino by triturating with successive portions of Diluted Alcohol, and percolate the solution through the Logwood until a pint of tincture is obtained." We have used this process and have not noticed gelatinization to take place in any instance. Sugar added in equal proportions with the kino employed has been recommended as a preventive of gelatinization, and R. Rother claims permanence for the following formula: Powder one and a half troyounces of kino and half a troyounce of catechu, mix them, add ten fluidounces of water, heat for ten or fifteen minutes with constant stirring, and let the mixture cool. Add water to make the mixture twelve fluidounces, and then add four fluidounces of alcohol. Pour the mixture into a bottle containing sixty grains of filter-paper, shake the whole well at intervals, and strain the tincture after twenty-four hours. (*A. J. P.,* 1886, 333.)

An important change in the process of the U. S. Pharmacopœia VIII was the employment of heat. This was due to the researches of Edmund White (*P. J.,* 1903, May, 644, and Nov., 702), who with David Hooper believes that the gelatinization of tincture of kino is due to an enzyme or oxydase present in the kino; the activity of this is destroyed by heat. Tincture of kino is one of the most frequently prescribed astringents, especially in the treatment of *diarrhea.*

Dose, one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Tinctura Kino et Opii Composita, *N. F.*

TINCTURA KRAMERIÆ. Br.

TINCTURE OF KRAMERIA

(tĭnc-tū'rą krą-mē'rī-æ)

Tincture of Rhatany; Teinture (alcoolé) de Ratanhia, *Fr. Cod.;* Tinctura Ratanhiæ, *P. G.;* Ratanhiatinktur, *G.*

Tincture of krameria was deleted from the U. S. P. IX, but retained in the Br. Pharm. 1914 and added to the N. F. IV (see Part III). The British tincture closely resembles the former U. S. P. preparation.

"Krameria Root, in No. 40 powder, 200 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

It is stated that the tincture made from Pará rhatany furnishes a clear solution on the addition of water, while that from Peruvian root yields a turbid mixture.

The same precaution should be observed in keeping this tincture as is recommended for tincture of kino. It is a good preparation in cases which admit of the use of small quantities of alcohol.

Dose, one or two fluidrachms (3.75 or 7.5 mils).

TINCTURA LACTUCARII. U. S.

TINCTURE OF LACTUCARIUM Tr. Lactucar.

(tĭnc-tū'rą lăc-tū-cā'rĭ-ī)

Teinture (alcoolé) de Lactucarium, *Fr.;* Lactucariumtinktur, *G.*

* "Lactucarium, *five hundred grammes* [or 17 ounces av., 279 grains]; Glycerin, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]; Alcohol, Purified Petroleum Benzin, Diluted Alcohol, Water, each, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Beat the lactucarium with clean sand, in an iron mortar, to a coarse powder, and then transfer it to a bottle; add *two thousand mils* [or 67 fluidounces, 301 minims] of purified petroleum benzin, cork the bottle tightly, and set it aside for forty-eight hours, frequently agitating the mixture. Pour the mixture on a double filter, cover the funnel, and, when the liquid has passed through the filter, wash the residue gradually with *fifteen hundred mils* [or 50 fluidounces, 345 minims] of purified petroleum benzin, and allow the lactucarium to dry by exposing it to a current of air. When it is dry and free from the odor of benzin, reduce it to a powder, using more sand, if necessary, and pack it moderately in a conical percolator. Mix the

glycerin with *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of water, and *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol, and gradually pour this mixture on the powder. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding first the remainder of the menstruum, and then diluted alcohol until the drug is exhausted. Reserve the first *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] of the percolate, evaporate the remainder on a water bath, at a temperature not exceeding 70° C. (158° F.), until it measures *two hundred and fifty mils* [or 8 fluidounces, 218 minims], and mix this with the reserved portion. Filter the mixed liquids and wash the filter with sufficient diluted alcohol to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

This tincture was first official in the U. S. 1890. It is based on the formula of J. L. Lemberger, who recommended the extraction of the resinous inert lactucerin by treatment with petroleum benzin. Great care must be observed to use *purified* petroleum benzin, as it is almost impossible to get rid of the odor and taste of petroleum in the finished preparation if the ordinary benzin be used. It is as useless as the other preparations of lactucarium.

Dose, half to one fluidrachm (1.8–3.75 mils).

Off. Prep.—Syrupus Lactucarii, *U. S.*

TINCTURA LAVANDULÆ COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF LAVENDER Tr. Lavand. Co. [Compound Spirit of Lavender]

(tĭnc-tū'rą lą-văn'dŭ-læ cŏm-pŏs'ĭ-tą)

Spiritus Lavandulæ Compositus, *U. S.* 1870; Lavender Drops; Teinture (alcoolé) de Lavande composée, *Fr.*; Zusammengesetzte Lavendeltinktur, *G.*

* "Oil of Lavender, *eight mils* [or 130 minims]; Oil of Rosemary, *two mils* [or 32 minims]; Saigon Cinnamon, in No. 50 powder, *twenty grammes* [or 308.6 grains]; Clove, in No. 50 powder, *five grammes* [or 77 grains]; Myristica, in No. 50 powder, *ten grammes* [or 154 grains]; Red Saunders, in No. 50 powder, *ten grammes* [or 154 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), macerating the powders in a mixture of *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] of alcohol, in which the oils have been dissolved, and *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of water. Complete the preparation with a mixture of *three volumes* of alcohol and *one volume* of water." *U. S.*

"Oil of Lavender, 5.0 *millilitres;* Oil of Rosemary, 0.5 *millilitre;* Cinnamon Bark, bruised, 10.0 *grammes;* Nutmeg, bruised, 10.0 *grammes;* Red Saunders Wood, rasped, 20.0 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000.0 *millilitres.* Macerate the solid ingredients and the Oils with nine hundred millilitres of the Alcohol for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The compound tincture of lavender of the U. S. Pharmacopœia is nearly twice the strength of the British preparation, although it is made with a menstruum weaker in alcohol. When properly prepared it is an excellent preparation to be used for *gastric uneasiness, nausea,* and *flatulence.*

Dose, from thirty minims to a fluidrachm (1.8–3.75 mils).

TINCTURA LIMONIS CORTICIS. U. S. (Br.)

TINCTURE OF LEMON PEEL Tr. Limon. Cort.

(tĭnc-tū'rą lĭ-mō'nĭs cŏr'tĭ-cĭs)

Tinctura Limonis, *Br.;* Tincture of Lemon; Teinture (alcoolé) de Zeste de Citron, *Fr.;* Citronenschalentinktur, *G.*

* "Lemon Peel, grated from the fresh fruit, *five hundred grammes* [or 17 ounces av., 279 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), macerating the drug in *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of alcohol and completing the preparation with alcohol. Use purified cotton as the filtering medium." *U. S.*

"Lemon Peel, cut small, 250 *grammes;* Alcohol (90 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

Tincture of lemon peel was a new official preparation of the U. S. P. VIII. Spirit of lemon made from oil of lemon was abandoned, because the poor quality of the oil with which it was likely to be made caused it to have a terebinthinate flavor. The 50 per cent. tincture made by macerating fresh lemon peel in alcohol was proposed by Scoville and the present formula produces a very satisfactory preparation.

This tincture was doubled in strength at the 1898 revision of the Br. Pharm., but is now only about one-half the strength of the U. S. tincture. It is made with strong alcohol instead of proof spirit formerly used. It forms a grateful aromatic addition to tonic infusions, etc.

Dose, from one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Syrupus Acidi Citrici, *U. S.*

TINCTURA LOBELIÆ. U. S.

TINCTURE OF LOBELIA Tr. Lobel. [Lobeliæ tinctura P. I.]

(tĭnc-tū'rą lo-bē'lĭ-æ)

Teinture (alcoolé) de Lobélie enflée, *Fr. Cod.;* Tinctura Lobeliae, *P. G.;* Lobelientinktur, *G.;* Tintura di lobelia, *It.;* Tintura alcoholica de lobelia, *Sp.*

* "Lobelia, in No. 50 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process

P (see page 1160), using diluted alcohol as the menstruum." *U. S.*

The strength of this tincture is the same as that of the U. S. P. VIII, which is one-half that of the U. S. 1890. For method of assay, see *C. D.*, 1893, 454; also *P. J.*, 1895, 141. It possesses the emetic and narcotic properties of lobelia, and is much used in *asthma.* A saturated tincture is strongly recommended by A. Livezey as a local application in *erysipelas,* and in the *eczematous eruption* of *Rhus poisoning.* (*B. M. S. J.*, lv, 262.)

Dose, as an expectorant, fifteen to thirty minims (0.9–1.8 mils).

TINCTURA LOBELIÆ ÆTHEREA. Br.

ETHEREAL TINCTURE OF LOBELIA

(tĭnc-tū'rą lo-bē'lĭ-æ æ-thē'rę-ą)

Teinture éthérée de Lobélie enflée, *Fr.*; Ätherische Lobelientinktur, *G.*

"Lobelia, in No. 40 powder, 200 *grammes;* Spirit of Ether, sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred *millilitres* of the Spirit of Ether, and complete the *percolation process.*" *Br.*

It should be noted that this tincture is twice the strength of the U. S. tincture and the International Protocol.

Dose, from five to fifteen minims (0.3–0.9 mils).

TINCTURA MOSCHI. U. S.

TINCTURE OF MUSK Tr. Mosch.

(tĭnc-tū'rą mŏs'ḳhī)

Teinture (alcoolé) de Musc, *Fr. Cod.*; Moschustinktur, *G.*; Tintura di muschio, *It.*; Tintura alcoholica de almizcle, *Sp.*

* "Musk, *five grammes* [or 77 grains]; Alcohol, *forty-five mils* [or 1 fluidounce, 250 minims]; Water, *forty-five mils* [or 1 fluidounce, 250 minims]; Diluted Alcohol, *a sufficient quantity,* to make *one hundred mils* [or 3 fluidounces, 183 minims]. Triturate the musk with the water gradually added until a smooth mixture is obtained; transfer this to a bottle and allow the mixture to macerate for twenty-four hours; then add the alcohol and macerate the mixture for six days, with occasional agitation. Transfer this mixture to a plain paper filter, and, when the liquid has drained off completely, wash the residue on the filter with sufficient diluted alcohol to make *one hundred mils* [or 3 fluidounces, 183 minims] of Tincture." *U. S.*

This tincture was reduced in strength about one-half in the U. S. P. 1890, on account of the greatly increased cost of musk. This change, in our opinion, was ill-advised, and does not secure the main object, as the patient will have to take double the dose, even if the alcohol be therapeutically contraindicated. The process has been arranged so as to make the end-product 100 mils, as very few pharmacists will require 1000 mils of tincture of musk. Musk will yield its virtues to the above menstruum if the process be followed; if wanted for its odor it will be economy to add a minim of solution of sodium hydroxide to the water used to rub the musk into a smooth paste. Care should be especially taken to use pure grain musk in this preparation.

Dose, from thirty minims to two fluidrachms (1.8–7.5 mils).

TINCTURA MYRRHÆ. U. S., Br.

TINCTURE OF MYRRH Tr. Myrrh.

(tĭnc-tū'rą mŷr'rhæ)

Teinture (alcoolé) de Myrrhe, *Fr. Cod.*; Tinctura Myrrhae, *P. G.*; Myrrhentinktur, *G.*; Tintura di mirra, *It.*; Tintura alcoholica de mirra, *Sp.*

* "Myrrh, in moderately coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), using alcohol as the solvent." *U. S.*

"Myrrh, in coarse powder, 200 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Macerate the Myrrh with eight hundred millilitres of the Alcohol in a closed vessel for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The strength of this tincture was increased 60 per cent. at the revision of the British Pharmacopœia (1898) and is now equivalent to the U. S. preparation.

Official alcohol is preferable to diluted alcohol as a solvent of myrrh, because it forms a perfectly clear tincture, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. According to E. B. Shuttleworth (*A. J. P.*, xliii, 369), the gum which is left behind in making the tincture may be utilized for making mucilage. The tincture of myrrh is used solely as a local application to stimulate *indolent and foul ulcers, spongy gums, aphthous sore mouth,* and *ulcerations of the throat.*

Dose, from fifteen to thirty minims (0.9–1.8 mils).

TINCTURA NUCIS VOMICÆ. U. S., Br.

TINCTURE OF NUX VOMICA Tr. Nuc. Vom. [Strychni tinctura P. I.]

(tĭnc-tū'rą nū'cĭs vŏm'ḭ-çæ)

"*One hundred mils* of Tincture of Nux Vomica yields not less than 0.237 Gm. nor more than 0.263 Gm. of the alkaloids of nux vomica." *U. S.* "Tincture of Nux Vomica contains in 100 millilitres 0.125 gramme of strychnine." *Br.*

Teinture (alcoolé) de Noix vomique, *Fr. Cod.*; Tinctura Strychni, *P. G.*; Brechnusstinktur, Krähenaugentinktur, *G.*; Tintura di noce vomica, *It.*; Tintura alcoholica de nuez vomica, *Sp.*

* "Nux Vomica, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make about *one thousand millilitres* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed

tinctures (see page 1160), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.25 Gm. of the alkaloids of nux vomica. The rate of flow for the percolate should not exceed ten drops per minute." *U. S.*

"Liquid Extract of Nux Vomica, 50 *millilitres;* Distilled Water, 150 *millilitres;* Alcohol (90 per cent.), sufficient to produce 600 *millilitres.* Mix; filter if necessary. Examined by the process described under 'Extractum Nucis Vomicæ Liquidum,' Tincture of Nux Vomica is found to contain in 100 millilitres 0.125 gramme of strychnine. *Limit of error* 0.005 gramme in excess or defect. This Tincture contains in each millilitre 1.25 milligrams of strychnine; each fluidrachm contains about 1/16 grain. It contains approximately the same proportion of strychnine as the Tinctura Nucis Vomica of the International Agreement, and one-half of that contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

Assay.—"Evaporate 100 mils of Tincture of Nux Vomica on a water bath until it measures about 10 mils, transfer the evaporated liquid to a separator, and proceed as directed in the assay under *Fluidextractum Belladonnæ Radicis,* page 486, second line of the Assay, beginning with the words 'add 10 mils,' modifying the process there given by using 5 mils of ammonia water with a little distilled water, in divided portions, to rinse the dish in which the Tincture was evaporated and by dissolving the residue in 10 mils of tenth-normal sulphuric acid V.S. instead of 5 mils.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 36.4 milligrammes of the alkaloids of nux vomica." *U. S.*

In the U. S. VIII this tincture was made from the extract, the object being to secure a more reliable and definite tincture than was possible under the process official prior to 1890; for this reason 2 per cent. of the standardized extract was directed to be dissolved in a mixture of 3 volumes of alcohol and 1 volume of water. On account of the very tough structure of nux vomica, percolation was accomplished usually with varying results. The amount of extract present in the percolate was to some extent a measure of its activity; hence, if a weighed portion of the percolate was evaporated to dryness, and the percentage of dry extract noted, it was easy to calculate the amount present in the whole quantity. The standard for Tincture of Nux Vomica was changed in the U. S. P. IX from 0.1 Gm. of strychnine in 100 mils to 0.25 Gm. in 100 mils of the alkaloids of nux vomica and instead of making the tincture from a definite quantity of extract of nux vomica percolation of the powdered drug is used. It is true that the tincture must be assayed, and the pharmacist, for this reason, must depend on the manufacturer for his supply, as it is unprofitable to assay small quantities of the tincture. We believe that more uniform results were obtained for the U. S. P. VIII tincture than will be for that of the U. S. P. IX, although the U. S. P. IX process is supposed to give a product of a more uniform color, which was the principal defect in the U. S. P. VIII product.

The British Pharmacopœia standardizes the liquid extract (see page 496), and makes its tincture from it of such strength that 100 mils shall contain 0.125 Gm. of strychnine. R. Rother (*A. J. P.,* Jan., 1883), after experimenting with various substances, found that sodium chloride aided greatly in softening the bassorin-like substance in which the alkaloidal principles of nux vomica are embedded, and he proposes its use by adding it to the menstruum of diluted alcohol in the proportion of 120 grains to the pint (see *U. S. D.,* 16th ed., p. 1527).

The amount of strychnine in this tincture is so small that it is not to be recommended for producing the systemic effects of that alkaloid. Its most important use is as a bitter tonic in *gastric atony.*

Dose, of the tincture, ten to thirty minims (0.6–1.8 mils), to be increased if necessary.

Off. Prep.—Elixir Phosphori et Nucis Vomicæ, *N. F.*

TINCTURA OLIVERI CORTICIS. Br.

TINCTURE OF OLIVER'S BARK

(tĭnc-tū'rą ŏl-ĭ-vē'rī cŏr'tĭ-cīs)

"Oliver's Bark, in No. 40 powder, 100 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture has been used in Australia for a number of years and is now official in the Br. Pharm. 1914. It possesses the properties of an aromatic like cinnamon.

The *dose* is from one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA OPII. U. S., Br.

TINCTURE OF OPIUM Tr. Opii [Laudanum Opii tinctura P. I.]

(tĭnc-tū'rą ō'pĭ-ī)

"*One hundred mils* of Tincture of Opium yields not less than 0.95 Gm. nor more than 1.05 Gm. of anhydrous morphine." *U. S.* "Tincture of Opium contains in 100 millilitres 1 gramme of morphine, calculated as anhydrous." *Br.*

Tinctura Thebaica, Tinctura Meconii, Tinctura Extracti Opii; Teinture d'Extrait d'Opium, *Fr. Cod.;* Teinture (alcoolé) d'Opium, Teinture thébaïque, *Fr.;* Tinctura Opii Simplex, *P. G.;* Einfache Opiumtinktur, *G.;* Tintura di oppio, *It.;* Tintura alcoholica de opio, *Sp.*

* "Granulated Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, Diluted Alcohol, each, *a sufficient quantity,* to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]; Heat *four hundred mils* [or 13 fluidounces, 252 minims] of water to

boiling, and pour it on the granulated opium contained in a tared vessel, and weigh; then stir the mixture occasionally during twelve hours, restore the original weight by the addition of water, add *four hundred mils* [or 13 fluidounces, 252 minims] of alcohol, pour the mixture into a bottle, and continue the maceration for forty-eight hours, occasionally shaking the mixture. Then transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the original menstruum has ceased to drop, continue the percolation slowly, gradually adding sufficient diluted alcohol to make the percolate measure *nine hundred and fifty mils* [or 32 fluidounces, 59 minims]. Assay a portion of this percolate, as directed below, and, from the morphine content thus determined, ascertain by calculation the amount of anhydrous morphine in the remainder of the liquid and adjust the volume of the finished Tincture so that each *one hundred mils* contains 1 Gm. of anhydrous morphine." *U. S.*

U. S. Assay.—"Evaporate 80 mils of Tincture of Opium on a water bath until the alcohol is all removed. Then proceed as directed in the assay under *Opium,* page 817, twenty-third line of the Assay, beginning with the word 'Transfer.' The result of the assay indicates the amount of morphine obtained from 40 mils of the Tincture of Opium." *U. S.*

"Opium, 200 *grammes;* Alcohol (90 per cent.), Distilled Water, of each, *a sufficient quantity.* Rub the Opium to a paste with five hundred *millilitres* of Distilled Water, previously heated to at least 90° C. (194° F.); set aside for six hours; add five hundred *millilitres* of the Alcohol; mix thoroughly; set aside in a covered vessel for twenty-four hours; strain, and then press; mix the two liquids thus obtained; set aside for twenty-four hours; filter. Determine the proportion of morphine, calculated as anhydrous, in the strong tincture so prepared by the following process:

Br. Assay.—"Pour 40 millilitres of the liquid into a porcelain dish; evaporate on a water-bath until the volume is reduced to about 10 millilitres; mix the residual liquid in a mortar with 1 gramme of freshly slaked *lime;* dilute the mixture with *water* to 41 millilitres; set aside for half an hour, stirring from time to time. Filter off 25 millilitres of the liquid (representing 25 millilitres of the strong tincture) through a plaited filter, having a diameter of about one decimetre, into a convenient vessel; add 2.5 millilitres of *alcohol* (90 per cent.) and 15 millilitres of *ether;* shake the mixture; add 1 gramme of *ammonium chloride;* shake well and frequently during half an hour; set aside for twelve hours for the morphine to separate. Counterbalance two small filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with *ether;* remove the ethereal layer of the liquid in the vessel as completely as possible by means of a small pipette, and transfer it to the filter; rinse the vessel with 8 millilitres of *ether,* again transferring the ethereal layer, by means of the pipette, to the filter; wash the filter with a total amount of 5 millilitres of *ether* added slowly, and in portions; let the filter dry in the air; pour upon it the liquid in the bottle, in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the vessel with *morphinated water.* Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain and dry it, first at 60° C. (140° F.), and finally at 115° C. (239° F.) for two hours. Weigh the crystals in the inner filter, counterbalancing by the outer filter. Take 0.2 gramme of the crystals, and titrate, with *N/10 solution of sulphuric acid,* as directed under 'Opium.' Add to the weight of anhydrous morphine obtained, as indicated by the titration, 0.025 gramme, a proportion representing the average loss of morphine during the process. Having thus ascertained the proportion of morphine, calculated as anhydrous, present in 25 millilitres of the strong tincture, dilute the remainder of the latter with sufficient of a mixture of Alcohol (90 per cent.) and Distilled Water, in equal volumes, to produce Tincture of Opium containing 1 gramme of morphine, calculated as anhydrous, in 100 millilitres. Examined by the foregoing process, Tincture of Opium is found to contain in 100 millilitres 1 gramme of morphine, calculated as anhydrous. *Limit of error* 0.05 gramme in excess or defect. This Tincture contains in 100 millilitres 1 gramme of morphine, calculated as anhydrous; 110 minims contain 1 grain of the same. It is of approximately the same strength as the Tinctura Opii of the International Agreement, and is about one-third stronger than the corresponding preparation of the British Pharmacopœia, 1898. Tincture of Opium may be prepared with any variety of opium containing a known percentage of morphine, calculated as anhydrous, provided that the percentage is not less than seven and a half, and provided that the resulting Tincture of Opium responds to the foregoing test." *Br.*

The proportion of opium in these formulas is the same, the finished tincture in both U. S. and Br. Pharmacopœias containing 1 Gm. of anhydrous morphine in 100 mils. The Br. Pharm., 1914, does not direct opium *in powder,* but relies upon an assay to bring the product to a uniform strength. The drying and granulating of the opium are clearly useful provisions, as they insure greater uniformity in the strength of the tincture. Crude opium contains variable proportions of water, and laudanum prepared from a moist specimen will be weaker than that prepared from an equal weight of the dried. The granulation insures the previous drying of the drug, and is thus useful independently of the greater facility which it gives to the action of the menstruum; it is, however, often neglected. Deviation from the official strength

in so important a preparation is certainly a great evil. There can be little doubt, we think, that the present U. S. formula insures a more complete exhaustion of the opium than did the former simple procedure of maceration for six days, while the saving in time is apparent. Granulated opium is preferred to powdered opium because of the greater facility of extraction. Opium in fine powder cannot be readily percolated with diluted alcohol, but if it be mixed with an equal weight of an insoluble powder like purified talc there will be no difficulty; percolation will necessarily be slow, but this is just what is required to secure thorough exhaustion.

In the United States and Great Britain this tincture is universally known by the name of *laudanum*. As this term was formerly applied to other preparations of opium, and still continues to be so applied on the continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum*, which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which the preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter, but containing traces of morphine. According to the requirements of the Pharmacopœia, 10 minims of this tincture will contain about one-tenth of a grain of morphine. Because of the other narcotic principles of opium, however, the clinical effects are somewhat stronger; the narcotic action of ten minims of the tincture of opium (0.6 mil) is nearly equivalent to one-sixth of a grain (0.01 Gm.) of morphine. Its action differs slightly from that of pure morphine, it being more constipating and more nauseating. As pointed out under opium the other alkaloids present seem to lessen the depressant effect of morphine upon the respiratory center so that the crude drug is a somewhat safer form of narcotic than pure opium.

The tincture of opium is probably the best of the official preparations where the effects of the whole drug are desired. It should be recollected that a fluidrachm of laudanum will yield on an average about one-hundred and twenty drops. When long kept with occasional exposure to the air, it becomes thick from the evaporation of a portion of the alcohol and the deposition of solid matter. If given in this state, it often acts with unexpected energy, and death has resulted in infants from doses which would have been entirely safe if the tincture had not been concentrated in this way.

Dose, five to ten minims (0.3–0.6 mil).

Off. Prep.—Linimentum Opii, *Br.;* Tinctura Camphoræ Composita, *Br.;* Tinctura Opii Ammoniata, *Br.;* Linimentum Opii Compositum, *N. F.;* Lotio Plumbi et Opii, *N. F.;* Mistura Camphoræ Acida, *N. TINCTURA OPII AMMONIATA. Br.

AMMONIATED TINCTURE OF OPIUM

(tĭnc-tū'rą ō'pĭ-ī ąm-mō-nĭ-ā'tą)

Scotch Paregoric; Teinture d'Opium ammoniacale, *Fr.;* Ammoniakalische Opiumtinktur, *G.*

"Tincture of Opium, 100 *millilitres;* Benzoic Acid, 20 *grammes;* Oil of Anise, 5 *millilitres;* Solution of Ammonia, 200 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres*. Dissolve the Oil of Anise and the Benzoic Acid in six hundred millilitres of the Alcohol; add the Tincture of Opium and the Solution of Ammonia; mix; filter; add sufficient of the Alcohol to produce the required volume. This Tincture contains in 100 millilitres 0.1 gramme of morphine, calculated as anhydrous; 110 minims contain about 1/10 grain of the same. It contains approximately one-tenth less morphine than that contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This is an old preparation of the Edinburgh Pharmacopœia, formerly used in Scotland under the name of *Paregoric Elixir*. It differs, however, both in composition and in strength, from the very popular preparation known as Paregoric in the United States.

Dose, from thirty minims to a fluidrachm (1.8–3.75 mils).

TINCTURA OPII CAMPHORATA. U. S. (Br.)

CAMPHORATED TINCTURE OF OPIUM Tr. Opii Camph. [Paregoric, Opii tinctura benzoici P. I.]

(tĭnc-tū'rą ō'pĭ-ī cămp-phọ-rā'tą)

Tinctura Camphoræ Composita, *Br.;* Compound Tincture of Camphor; Paregoric Elixir; Elixir parégorique; *Fr. Cod.;* Teinture (alcoolé) d'Opium Camphrée, *Fr.;* Tinctura Extracti Opii Camphorata, Elixir Paregoricum, Tinctura Opii benzoïca, *P. G.;* Benzoësaurehaltige Opiumtinktur, *G.*

* "Powdered Opium, *four grammes* [or 62 grains]; Benzoic Acid, *four grammes* [or 62 grains]; Camphor, *four grammes* [or 62 grains]; Oil of Anise, *four mils* [or 65 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M (see page 1160), macerating the above ingredients in a mixture of *forty mils* [or 1 fluidounce, 169 minims] of glycerin and *nine hundred and fifty mils* [or 32 fluidounces, 59 minims] of diluted alcohol. Complete the preparation with diluted alcohol." *U. S.*

"Tincture of Opium, 50 *millilitres;* Benzoic Acid, 5 *grammes;* Camphor, 3 *grammes;* Oil of Anise, 3 *millilitres;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres*. Dissolve the Benzoic Acid, Camphor, and Oil of Anise in nine hundred *millilitres* of the Alcohol; add the Tincture of Opium and sufficient of the Alcohol to produce the required volume; filter if necessary. This Compound Tincture contains

in 10 millilitres 5 milligrammes (0.005 gramme) of morphine, calculated as anhydrous; and in each fluid drachm about one thirty-seventh of a grain of the same. It contains approximately one-tenth more morphine than the Tinctura Opii Benzoica of the International Agreement, and one-tenth more than was contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This is the well-known *paregoric.* It is widely employed with the idea that it is a mild anodyne for the relief of *cough, nausea,* and abdominal *pains.* As its narcotic effects depend, however, entirely upon the opium which it contains its mildness is due solely to the fact that it is usually given in relatively small doses. In *diarrheas* the effect of the opium is somewhat enhanced by the camphor. The superstition that it is especially suited for children is senseless; if morphine be indicated for infants the alkaloid itself is just as useful if given in equivalent dose. One-half a fluidounce (15 mils) of either the United States or British tincture contains about nine-tenths of a grain of powdered opium.

Dose, for an infant, from five to twenty minims (0.3–1.3 mils); for an adult, from one to four fluidrachms (3.75–15.0 mils).

For a description of *Bateman's drops* and *Godfrey's cordial,* see *Tinctura Pectoralis* (Part III) and *Mistura Opii et Sassafras* (Part III), respectively.

Off. Prep.—Mistura Glycyrrhizæ Composita, *U. S.;* Mistura Pectoralis, Stokes, *N. F.*

TINCTURA OPII DEODORATI. U. S.

TINCTURE OF DEODORIZED OPIUM Tr. Opii Deod.

(tĭnc-tū'ra ō'pī-ī dę-ō-dǫ-rā'tī)

"*One hundred mils* of Tincture of Deodorized Opium yields not less than 0.95 Gm. nor more than 1.05 Gm. of anhydrous morphine." *U. S.*

Deodorized tincture of opium, *U. S.* 1880; Teinture (alcoolé) d'Opium sans odeur, *Fr.;* Desodorirte Opiumtinktur, *G.*

* "Granulated Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Purified Petroleum Benzin, *seventy-five mils* [or 2 fluidounces, 257 minims]; Alcohol, *two hundred mils* [or 6 fluidounces, 366 minims]; Water, *a sufficient quantity,* to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Heat *five hundred mils* [or 16 fluidounces, 435 minims] of water to boiling, and pour it on the granulated opium contained in a suitable vessel, stirring the mixture frequently during twenty-four hours. Then transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the original menstruum has ceased to drop, continue the percolation slowly, gradually adding water until the opium is practically exhausted. Concentrate the percolate, by evaporation on a water bath, until it measures *one hundred and fifty mils* [or 5 fluidounces, 35 minims]; cool, transfer it to a bottle, add *sixty-five mils* [or 2 fluidounces, 95 minims] of purified petroleum benzin, stopper, and shake the mixture frequently during ten minutes. Separate the benzin layer and repeat the shaking out with the remainder of the purified petroleum benzin, carefully and completely separating the benzin layer each time. Allow the aqueous liquid to evaporate spontaneously in a warm place until the odor of benzin has almost disappeared, remove the last traces by cautiously heating on a water bath and then add *six hundred mils* [or 20 fluidounces, 138 minims] of water. Filter the liquid, add the alcohol and wash the residue on the filter with sufficient water to make the product measure *nine hundred and fifty mils* [or 32 fluidounces, 59 minims]. Assay a portion of this filtrate as directed below, and, from the morphine content thus determined, ascertain by calculation the amount of anhydrous morphine in the remainder of the liquid and adjust the volume of the finished tincture so that each *one hundred mils* contains 1 Gm. of anhydrous morphine.

"**Assay.**—Proceed as directed in the assay under *Tinctura Opii.*" *U. S.*

A liquid extract is first made from granulated opium in which are left behind all the ingredients of opium insoluble in water; and this, being well shaken with purified benzin, is further deprived of all the principles soluble in this fluid, including narcotine and the noxious odorous matter. The purified benzin is then entirely separated, and, the residue having been dissolved in water, the solution is filtered, and mixed with enough alcohol to preserve it. It had been repeatedly recommended by several pharmacists to replace the ether used in the U. S. P., 1890, process with petroleum benzin, which removes the narcotine just as well as does the ether, and has the merit of being much cheaper. The objection, however, was that benzin almost invariably leaves a trace of a taste and an odor like those of petroleum, and hence it is not fitted for use in a remedy used almost exclusively internally, but the employment of purified petroleum benzin in the U. S. P. IX should obviate this objection. Patch found that acetone, which had been suggested as a substitute for ether, was open to the same objection as petroleum benzin.

Frederick T. Gordon (*A. J. P.,* 1900, 576) recommends an improved process for preparing tincture of deodorized opium in which he proposes paraffin in place of ether for deodorizing the aqueous extract of opium. The opium, in a granulated condition, is extracted with water practically as directed by the Pharmacopœia. The first 300 mils of percolate from 100 Gm. of drug are received, the subsequent portions are evaporated to 200 mils, and the two portions, being mixed, are heated to 82° C. (180° F.). Then 150 Gm. of paraffin U. S. P. are added, and when this has melted the mixture is shaken thoroughly for five or ten minutes and set aside to cool. When the paraffin has hardened, the crust is broken and the aqueous opium solution poured out, the under side of the paraffin

crusts being washed with a little water and the washings added to the decanted liquid, which is brought to 800 mils. To this, 200 mils of alcohol are added and finally enough water to make 1000 mils of finished product. The paraffin removes the narcotine and odorous matter, but none of the morphine (the latter existing in the opium, as is well known, as meconate, and this is insoluble in the melted paraffin). Wm. S. White also proposes the use of melted paraffin in preparing the tincture of deodorized opium instead of the inflammable benzin authorized by the U. S. P. He states that 70 Gm. of paraffin to each liter of the preparation is sufficient, and all that is necessary is to warm the evaporated extract, add the melted paraffin, agitate well and allow to stand over night, when the paraffin may readily be removed as a solid cake. He states also that the morphine obtained in assaying the tincture made by this method is remarkably white and pure. (*J. A. Ph. A.*, 1913, p. 939.) A. E. Ebert (*A. J. P.*, 1902, 157) prefers gasoline to benzin and objects to the use of paraffin, or paraffin oils because of their liability to dissolve some of the morphine; he recommends a *concentrated liquid opium* to be used in making the various galenical opium preparations. This tincture is practically equivalent in therapeutic effect to the simple tincture of opium and is by many preferred because of its less offensive odor. The experiments of Macht, however (see *Opium*), indicate that the presence of narcotine is advantageous as it tends to neutralize the depressant action of the opium upon the respiratory center.

Dose, five to ten minims (0.3–0.6 mil).

Off. Prep.—Tinctura Ipecacuanhæ et Opii, *N. F.*

TINCTURA PHYSOSTIGMATIS. U. S.

TINCTURE OF PHYSOSTIGMA Tr. Physostig. [Tincture of Calabar Bean]

(tĭnc-tū′rą phȳ-sǫ-stĭg′mą-tĭs)

"*One hundred mils* of Tincture of Physostigma yields not less than 0.013 Gm. nor more than 0.017 Gm. of the alkaloids of physostigma." *U. S.*

Teinture (alcoolé) de fève du Calabar, *Fr.;* Kalabarbohnentinktur, *G.*

• "Physostigma, in No. 50 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a tincture by Type Process P, as modified for assayed tinctures (see page 1160), using alcohol as the menstruum and adjusting the volume of the finished tincture so that each *one hundred mils* contains 0.015 Gm. of the alkaloids of physostigma.

"**Assay.**—Evaporate 150 mils of Tincture of Physostigma on a water bath until it measures about 20 mils, add 10 Gm. of sawdust purified (see Reagents, Part III), to the liquid and incorporate it thoroughly. Continue the evaporation on a water bath until the mixture is dry, then transfer the impregnated sawdust to a 250 mil flask, and proceed as directed in the assay under *Physostigma,* page 850, third line of the Assay, beginning with the words 'and add 150 mils of ether,' modifying the process there given by using the solution of sodium bicarbonate, in divided portions, to rinse the evaporating dish." *U. S.*

This tincture was reduced from 15 Gm. (U. S. P., 1890) to 10 Gm. of drug per 100 mils in the U. S. P. VIII and an assay process appended; the U. S. P. IX has retained this strength. This *tincture of Calabar Bean* is much weaker than that proposed by Fraser, which was nearly as strong as a fluidextract—five minims representing three grains of the drug.

Dose, of the official tincture, from ten to thirty minims (0.6–1.8 mils).

TINCTURA PICRORHIZÆ. Br.

TINCTURE OF PICRORHIZA

(tĭnc-tū′rą pĭc-rō-rhī′zæ)

"Picrorhiza, cut small and bruised, 250 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

Although "this Tincture is of twice the strength of the corresponding preparation of the Indian and Colonial Addendum, 1900," *Br.,* the proportion of alcohol in this tincture is too large for it to be available as an antiperiodic; it is used as a bitter tonic.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA PODOPHYLLI. Br.

TINCTURE OF PODOPHYLLUM

(tĭnc-tū′rą pŏd-ǫ-phȳl′lī)

Teinture (alcoolé) de Résine de Podophyllum, *Fr.;* Podophyllintinktur, *G.*

"Podophyllum Resin, 36.5 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Add the Podophyllum Resin to nine hundred *millilitres* of the Alcohol, and set aside for twenty-four hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

The introduction of this tincture is of doubtful utility.

Dose, five to fifteen minims (0.3–0.9 mil).

TINCTURA PODOPHYLLI INDICI. Br.

TINCTURE OF INDIAN PODOPHYLLUM

(tĭnc-tū′rą pō-dō -phȳl′lī ĭn′dĭ-cī)

"Indian Podophyllum Resin, 36.5 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Add the Indian Podophyllum Resin to nine hundred millilitres of the Alcohol, and set aside for twenty-four hours, shaking occasionally; filter; pass sufficient of the Alcohol

through the filter to produce the required volume." *Br.*

This has been introduced to afford a substitute in the Asiatic provinces for the tincture of podophyllum.

Dose, five to fifteen minims (0.3–0.9 mil).

TINCTURA PRUNI VIRGINIANÆ. Br.

TINCTURE OF WILD CHERRY

(tĭnc-tū'rą prū'nī vĭr-ĝĭn-ĭ-ā'næ)

Tincture of Virginian Prune; Teinture (alcoolé) d'Ecorce de Cerisier, *Fr.*; Wildkirschenrindentinktur, *G.*

"Wild Cherry Bark, in No. 20 powder, 200 *grammes;* Alcohol (90 per cent.), 565 *millilitres;* Distilled Water, 365 *millilitres;* Glycerin, 100 *millilitres.* Mix the powder with the Distilled Water; set aside in a closed vessel for twenty-four hours; add the Alcohol, and complete the *maceration process;* add the Glycerin to the product." *Br.*

This was a new official tincture of the Br. Pharm., 1898; its utility is doubtful. The English name has been changed from Virginian Prune to Wild Cherry in the Br. Pharm., 1914. The use of the glycerin serves to retard precipitation.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA PYRETHRI. U. S., Br.

TINCTURE OF PYRETHRUM Tr. Pyreth. [Tincture of Pellitory]

(tĭnc-tū'rą pȳ-rē'thrī)

Teinture (alcoolé) de Pyrèthre (racine), *Fr. Cod.*; Bertramwurzeltinktur, *G.*

* "Pyrethrum, in No. 50 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using alcohol as the menstruum." *U. S.*

"Pyrethrum Root, in No. 40 powder, 200 *grammes;* Alcohol (70 per cent.), sufficient to produce, 1000 *millilitres.* Moisten the powder with one hundred and fifty millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is a powerful local irritant, and is an ingredient in several well-known mouth and tooth washes. For its uses, which are purely external, see *Pyrethrum.*

TINCTURA QUASSIÆ. U. S. Br.

TINCTURE OF QUASSIA Tr. Quass.

(tĭnc-tū'rą quas'sĭ-æ)

Teinture (alcoolé) de Quassie Amère, *Fr.*; Quassiatinktur, *G.*

* "Quassia, in No. 50 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *one volume* of alcohol and *two volumes* of water as the menstruum." *U. S.*

"Quassia Wood, rasped, 100 *grammes;* Alcohol (45 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

The strength of this tincture was doubled in the U. S. P. VIII and is twice that of the present British tincture. It may be employed as an addition to tonic infusions or mixtures. It has the advantage that, being free from tannin, it may be given in conjunction with salts of iron.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA QUILLAIÆ. Br.

TINCTURE OF QUILLAIA

(tĭnc-tū'rą quĭl-lā'iæ)

Teinture (alcoolé) d'Ecorce de Quillaya, *Fr.*; Seifenrindentinktur, *G.*

Tincture of quillaja was deleted from the U. S. P. IX, but is now official in the N. F. IV. (see Part III).

"Quillaia Bark, in No. 20 powder, 50 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with twenty-five millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is almost exclusively used as an emulsifying agent. Its medicinal activity, however, limits its use. (See *Quillaja,* p. 928.) The British tincture is only one-fourth the strength of the preparation.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

TINCTURA QUININÆ. Br.

TINCTURE OF QUININE

(tĭnc-tū'rą quĭ-nī'næ)

Teinture (alcoolé) de Quinine, *Fr.*; Chinintinktur, *G.*

"Quinine Hydrochloride, 20 *grammes;* Tincture of Orange, 1000 *millilitres.* Dissolve." *Br.*

Quinine sulphate was replaced in this preparation by the hydrochloride in the 1885 Br. Pharmacopœia, because, as pointed out by Wright (*Y. B. P.*, 1884, 537), the sulphate was not always soluble in the proportion of tincture of orange peel ordered.

Dose, a fluidrachm (3.75 mils) (about equal to one and one-tenth grains of quinine hydrochloride).

TINCTURA QUININÆ AMMONIATA. Br.

AMMONIATED TINCTURE OF QUININE

(tĭnc-tū'rą quĭ-nī'næ ąm-mō-nĭ-ā'tą)

Teinture Ammoniacale de Quinine, *Fr.*; Ammoniakhaltige Chinintinktur, *G.*

"Quinine Sulphate, 20 *grammes;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), 900 *millilitres.* Mix the Solution of Ammonia with the Alcohol; add the Quinine Sulphate; shake until a clear solution is produced; set aside for three days; filter." *Br.*

Dose, one fluidrachm (3.75 mils), representing about one and one-tenth grains of quinine sulphate.

TINCTURA RHEI. U. S. (Br.)

TINCTURE OF RHUBARB Tr. Rhei

(tĭnc-tū'ra rhē'ī)

Tinctura Rhei Composita, *Br.*, Compound Tincture of Rhubarb; Teinture (alcoolé) de Rhubarbe, *Fr. Cod.*; Rhabarbertinktur, *G.*; Tintura di rabarbaro, *It.*

* "Rhubarb, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Cardamom Seed, in No. 40 powder, *thirty grammes* [or 1 ounce av., 25.5 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol and *four hundred mils* [or 13 fluidounces, 252 minims] of water as the first menstruum and completing the percolation with diluted alcohol." *U. S.*

"Rhubarb, in No. 20 powder, 100.0 *grammes;* Cardamom Seeds, in No. 20 powder, 12.5 *grammes;* Coriander Fruit, in No. 20 powder, 12.5 *grammes;* Glycerin, 100.0 *millilitres;* Alcohol (45 per cent.) sufficient to produce 1000.0 *millilitres.* Moisten the solid ingredients with one hundred millilitres of the Alcohol, and prepare, by the *percolation process,* eight hundred and fifty millilitres of tincture. Add the Glycerin, and sufficient of the Alcohol to produce the required volume." *Br.*

This tincture was doubled in rhubarb and cardamom strength in the U. S. P. (8th Rev.). The tincture of rhubarb on standing deposits a yellow precipitate. This has been shown by James T. King (*A. J. P.,* xlii) to be in most cases largely composed of chrysophanic acid. He proposed to remedy this by the use of a stronger alcohol, or, as recommended by J. B. Moore (*A. J. P.,* xlv, 306), by the substitution of glycerin for a portion of the alcohol. We have not found that either of these plans entirely prevents precipitation, although glycerin is an aid in this direction.

Dose, from one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Mistura Opii et Rhei Composita, *N. F.*

TINCTURA RHEI AROMATICA. U. S.

AROMATIC TINCTURE OF RHUBARB Tr. Rhei Arom.

(tĭnc-tū'ra rhē'ī ăr-o-măt'ĭ-ca)

Teinture (alcoolé) de Rhubarbe aromatique, *Fr.*; Aromatische Rhabarbertinktur, *G.*

* "Rhubarb, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Saigon Cinnamon, in No. 40 powder, *forty grammes* [or 1 ounce av., 180 grains]; Clove, in No. 40 powder, *forty grammes* [or 1 ounce av., 180 grains]; Myristica, in No. 40 powder, *twenty grammes* [or 308.6 grains], to make *one thousand mils* [or 33 fluidounces. 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol and *four hundred mils* [or 13 fluidounces, 252 minims] of water as the first menstruum and completing the percolation with diluted alcohol." *U. S.*

This is the tincture which is used in making the aromatic syrup of rhubarb. It is preferable to separate the preparations, as it is occasionally desirable to prescribe the tincture without the admixture with syrup, while the pharmacist will always prefer to make the tincture in quantity and keep it on hand, since it is permanent, and add to it syrup to make the aromatic syrup when needed.

Dose, for an adult, from one-half to one fluidrachm (1.8–3.75 mils).

Off. Prep.—Syrupus Rhei Aromaticus, *U. S.*

TINCTURA SANGUINARIÆ. U. S.

TINCTURE OF SANGUINARIA Tr. Sanguin. [Tincture of Blood Root]

(tĭnc-tū'ra săn-guĭ-nā-rĭ-æ)

Teinture (alcoolé) de Sanguinaire, *Fr.*; Blutwurzeltinktur, *G.*

* "Sanguinaria, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Hydrochloric Acid, *ten mils* [or 162 minims]; Alcohol, Water, each, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred mils* [or 20 fluidounces, 138 minims] of alcohol with *four hundred mils* [or 13 fluidounces, 252 minims] of water. Moisten the drug with a mixture of the hydrochloric acid and *thirty mils* [or 1 fluidounce, 7 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum made of alcohol and water, in the same proportion as before, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

This tincture was reduced from 15 Gm. (U. S. P, 1890) to 10 Gm. of drug, per 100 mils, in the U. S. P. VIII and IX.

A precipitate will generally be found deposited upon the sides and bottoms of bottles containing this tincture. W. J. McConn (*A. J. P.,* 1884, p. 505) recommended the addition of an alkaline citrate, preferably potassium citrate, as a preventive. He found sanguinarine in the precipitate. See also Homerberg and Beringer (*A. J. P.,* 1913, lxxxv, p. 394). The official menstruum now contains hydrochloric acid, with a view of preventing precipitation. This tincture is emetic in the *dose* of from three to four fluidrachms (11.25–15 mils); but it is rather intended to act as an expectorant or an alterative, for which purpose from fifteen to sixty minims (0.9–3.75 mils) may be given.

TINCTURA SCILLÆ. U. S., Br.

TINCTURE OF SQUILL Tr. Scill.

(tĭnc-tū'rą sçĭl'læ)

"If assayed biologically the minimum lethal dose should not be greater than 0.006 mil of Tincture, or the equivalent in Tincture of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog." *U. S.*

Teinture (alcoolé) de Scille, *Fr. Cod.*; Meerzwiebeltinktur, *G.*; Tintura alcoholica de escila, *Sp.*

* "Squill, in No. 20 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Moisten the drug with sufficient menstruum, prepared by mixing *three volumes* of alcohol and *one volume* of water, and macerate it in a closed vessel in a moderately warm place for twenty-four hours, stirring occasionally. Then transfer it to a percolator, shake it down evenly without packing and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding sufficient of the same menstruum to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Tincture.

"**Assay.**—For a method of assaying Tincture of Squill, see Biological Assays (Part III)." *U. S.*

"Squill, bruised, 200 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

Tincture of Squill was reduced from the strength of 15 Gm. (U. S. P. 1890) to 10 Gm. of drug, per 100 mils, U. S. P. VIII and IX). This tincture yields a grayish, rose-colored, very bitter and acrid deposit, consisting of silky tufts. (Ménière.) The tincture represents the virtues of squill probably better than any other official preparation.

Dose, from ten to twenty minims (0.6–1.3 mils) (from twenty to forty drops).

TINCTURA SENEGÆ. Br.

TINCTURE OF SENEGA

(tĭnc-tū'rą sĕn'ę-gæ)

Teinture (alcoolé) de Polygala de Virginie, *Fr.*; Senegatinktur, *G.*

"Senega Root, in No. 40 powder, 200 *grammes;* Alcohol (60 per cent.), sufficient to produce, 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The Br. Pharm. 1898 increased the strength of this preparation 60 per cent. The tincture is efficient, but it is hardly needed while recourse can be had to the fluidextract or the syrup.

Dose, from thirty minims to two fluidrachms (1.8–7.5 mils).

TINCTURA SENNÆ COMPOSITA. Br.

COMPOUND TINCTURE OF SENNA

(tĭnc-tū'rą sĕn'næ cǫm-pŏs'ĭ-tą)

Elixir Salutis; Teinture (alcoolé) de Séné composée, Teinture de Séné aromatique, Elixir de Salut, *Fr.*; Zusammengesetzte Sennatinktur, *G.*

"Senna Leaves, in No. 20 powder, 200 *grammes;* Caraway Fruit, in No. 20 powder, 25 *grammes;* Coriander Fruit, in No. 20 powder, 25 *grammes;* Glycerin, 100 *millilitres;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Moisten the solid ingredients with two hundred and fifty millilitres of the Alcohol, and prepare, by the *percolation process,* eight hundred and fifty millilitres of tincture. Add the Glycerin and sufficient of the Alcohol to produce the required volume." *Br.*

The Br. Pharm. 1898 increased the proportion of senna in this preparation 60 per cent.

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in *costiveness* attended with flatulence, and in *atonic gout,* especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. Tincture of senna yields a yellow scaly deposit, containing white crystals of calcareous salts. (Ménière.)

Dose, from two to four fluidrachms (7.5–15 mils).

TINCTURA SERPENTARIÆ. Br.

TINCTURE OF SERPENTARY

(tĭnc-tū'rą sęr-pęn-tā'rĭ-æ)

Teinture (alcoolé) de Serpentaire de Virginie, *Fr.*; Schlangenwurzeltinktur, *G.*

"Serpentary Rhizome, in No. 40 powder, 200 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

Tincture of Serpentaria was doubled in strength in the U. S. P. VIII, but is now transferred to the N. F. (see Part III). This tincture is little other than a feebly aromatic, alcoholic stimulant. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent.

Dose, thirty minims to two fluidrachms (1.8–7.5 mils).

TINCTURA STRAMONII. U. S., Br.

TINCTURE OF STRAMONIUM Tr. Stramon.

(tĭnc-tū'rą strą-mō'nĭ-ī)

"*One hundred mils* of Tincture of Stramonium yields not less than 0.0225 Gm. nor more than 0.0275 Gm. of the total alkaloids of stramonium." *U. S.*

Tincture of Stramonium Leaves; Teinture (alcoolé) de Stramoine (feuille), *Fr. Cod.*; Stechapfelblättertinktur, *G.*

* "Stramonium, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to

make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures (see page 1160), using diluted alcohol as the menstruum and adjusting the volume of the finished Tincture so that each *one hundred mils* contains 0.025 Gm. of the total alkaloids of stramonium.

"**Assay.**—Evaporate 100 mils of Tincture of Stramonium on a water bath until it measures about 10 mils, transfer the evaporated liquid to a separator, and proceed as directed in the assay under *Fluidextractum Belladonnæ Radicis*, page 486, second line of the Assay, beginning with the words 'add 10 mils,' and modifying the process there given by using the ammonia water and about 5 mils of distilled water in addition to rinse the dish in which the Tincture was evaporated; before titrating treat the residue twice with 5 mils of ether, evaporating to dryness each time." *U. S.*

"Stramonium Leaves, in No. 20 powder, 200 *grammes;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with two hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

This tincture is now made from Stramonium leaves instead of the seeds as directed by the U. S. P. 1890, and the strength made 10 Gm. of drug, per 100 mils, instead of 15 Gm., as in the U. S. P. 1890, and an assay has been appended. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent., but changed the form of the drug from seeds to leaves. The British tincture is now double the strength of the U. S. P. tincture.

Dose, from ten to twenty minims (0.6–1.3 mils); of the British tincture, five to ten minims (0.3–0.6 mil).

TINCTURA STROPHANTHI. U. S., Br.

TINCTURE OF STROPHANTHUS Tr. Strophanth. [Strophanthi tinctura P. I.]

(tĭnc-tū'rą strǫ-phăn'thī)

"If assayed biologically the minimum lethal dose should not be greater than 0.00006 mil of Tincture, or the equivalent in Tincture of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog." *U. S.*

Teinture (alcoolé) de Strophantus Kombé, *Fr. Cod.;* Tinctura Strophanthi, *P. G.;* Strophanthustinktur, *G.;* Strophanthussamentinktur, *G.;* Tinctura di strofanto, *It.;* Tintura alcoholica de estrofanto, *Sp.*

* "Strophanthus, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Pack the drug in a cylindrical percolator and slowly percolate it with purified petroleum benzin until a few drops of the percolate, evaporated from filter paper, no longer leaves a greasy stain; then remove the strophanthus from the percolator and expose it to the air until it is dry and the odor of benzin has disappeared. Prepare a Tincture from this dried drug by Type Process P (see page 1160), using alcohol as the menstruum, but allow the moistened drug to macerate for forty-eight hours before starting the percolation, instead of twenty-four hours as directed in Type Process P.

"**Assay.**—For a method of assaying Tincture of Strophanthus, see Biological Assays (Part III)." *U. S.*

"Strophanthus Seeds, in No. 30 powder, dried at 45° C. (113° F.), 100 *grammes;* Ether, *a sufficient quantity;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Pack the powder in a percolator; moisten with the Ether, and macerate for twenty-four hours; then allow percolation to proceed, continuing the addition of the Ether until the liquid passes through colorless. Remove the marc from the percolator, and dry it, gradually heating it to 50° C. (122° F.). Again reduce it to powder, repack in the percolator, and moisten with the Alcohol. Macerate for forty-eight hours, then pour on successive quantities of the Alcohol, percolating slowly, until five hundred millilitres of percolate are obtained; add sufficient of the Alcohol to produce the required volume. This Tincture is made with four times the proportion of Strophanthus Seeds ordered for the corresponding preparation of the British Pharmacopœia, 1898. It is of approximately the same strength as the Tinctura Strophanthi of the International Agreement, but in the case of the latter Tincture, the seeds are not treated with ether for the removal of fat and resins." *Br.*

Strophanthus seeds are reduced to powder with great difficulty. E. R. Squibb bruises them (after drying perfectly) in an iron mortar with broken glass. (*Ephem.,* vol. iii, 1252.) Made by either the U. S. or Br. process, the tincture is usually slightly cloudy when first prepared, but on standing soon becomes clear. The use of petroleum benzin in the U. S. P. IX and ether in the Br. P. for the preliminary exhaustion of the drug is to effect the removal of the fixed oil which interferes with the stability of the preparation unless previously removed.

Uses.—The tincture of strophanthus fully represents the crude drug and may be used for all the purposes for which strophanthus is serviceable. It is apparently a stable preparation and although somewhat subject to variations in potency, according to Hatcher and Bailey (*J. A. M. A.,* 1909, lii, p. 5) is much more uniform in strength than tincture of digitalis.

Dose, three to eight minims (0.2–0.5 mil)

TINCTURA TOLUTANA. U. S., Br.

TINCTURE OF TOLU Tr. Tolu. [Tolu Tincture]

(tĭnc-tū'rą tō-lū-tā'ną)

Tincture of Balsam of Tolu; Teinture (alcoolé) de Baume de Tolu, *Fr. Cod.;* Tolubalsamtinktur, *G.*

* "Balsam of Tolu, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process

M (see page 1160), using alcohol as the solvent." *U. S.*

"Balsam of Tolu, 100 *grammes;* Alcohol (90 per cent.), sufficient to produce, 1000 *millilitres.* Dissolve the Balsam of Tolu in eight hundred *millilitres* of the Alcohol; filter; pass sufficient of the Alcohol through the filter to produce the required volume." *Br.*

This tincture was doubled in strength in the U. S. P. VIII. The British tincture (1914) is half the strength of the U. S. P. tincture.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in *chronic bronchitis,* but the proportion of alcohol is too large to allow of its advantageous use in some cases. It is used in preparing the syrup of tolu. In smaller quantities it is often employed to flavor cough mixtures. It is precipitated by aqueous liquids.

Dose, one-half to two fluidrachms (1.8–7.5 mils).

Off. Prep.—Syrupus Tolutanus, *U. S.*

TINCTURA URGINEÆ. Br.

TINCTURE OF URGINEA

(tĭnc-tū'rą ür-gĭ'nē-æ)

"Urginea, bruised, 200 *grammes;* Alcohol (60 per cent.), 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

This tincture was introduced into India and is intended to be used in place of squill.

The *dose* is five to fifteen minims (0.3–0.9 mil).

TINCTURA VALERIANÆ. U. S.

TINCTURE OF VALERIAN Tr. Valer.

(tĭnc-tū'rą vą-lē-rĭ-ā'næ)

Teinture (alcoolé) de Valériane, *Fr. Cod.;* Tinctura Valerianæ, *P. G.;* Baldriantinktur, *G.;* Tinturo di valeriana, *It.*

* "Valerian, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

The proportion of alcohol was increased in the U. S. 1890 tincture, to prevent precipitation, and this strength has been retained in the present revision. It is now three parts of alcohol to one part of water. The tincture possesses the properties of valerian, but cannot be given in some cases, so as to produce the full effects of the root, without stimulating too highly, in consequence of the large proportion of spirit. It deposits on standing a black, very cohesive precipitate, with starch, and a yellow extractive matter. (Ménière.)

Dose, one to four fluidrachms (3.75–15.0 mils).

TINCTURA VALERIANÆ AMMONIATA. U. S., Br.

AMMONIATED TINCTURE OF VALERIAN Tr. Valer. Ammon.

(tĭnc-tū'rą vą-lē-rĭ-ā'næ ąm-mō-nĭ-ā'tą)

Tinctura Valerianæ Composita; Teinture de Valériane ammoniacale, *Fr.;* Ammoniakalische Baldriantinktur, *G.*

* "Valerian, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using aromatic spirit of ammonia as the menstruum." *U. S.*

"Valerian Rhizome, in No. 40 powder, 200 *grammes;* Oil of Nutmeg, 3 *millilitres;* Oil of Lemon, 2 *millilitres;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), 900 *millilitres.* Mix the liquid ingredients, and, using the mixture as a menstruum, prepare by the *maceration process.*" *Br.*

The proportion of valerian was increased 60 per cent. in the Br. Pharm. 1898, and the aromatic spirit of ammonia replaced by alcohol, solution of ammonia, and volatile oils.

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medicinal action. The quantity of valerian was very judiciously increased one-third in the U. S. revision of 1880. The tincture is employed as an antispasmodic in *hysteria* and other *nervous diseases.*

Dose, from thirty minims to a fluidrachm (1.8–3.75 mils).

TINCTURA VALERIANÆ INDICÆ AMMONIATA. Br.

AMMONIATED TINCTURE OF INDIAN VALERIAN

(tĭnc-tū'rą vą-lē-rĭ-ā'næ ĭn'dĭ-cæ ąm-mō-nĭ-ā'tą)

"Indian Valerian Rhizome, in No. 40 powder, 200 *grammes;* Oil of Nutmeg, 3 *millilitres;* Oil of Lemon, 2 *millilitres;* Solution of Ammonia, 100 *millilitres;* Alcohol (60 per cent.), 900 *millilitres.* Mix the liquid ingredients, and, using the mixture as a menstruum, prepare by the *maceration process.*" *Br.*

This tincture was introduced into the Br. Pharm. 1914 to be used in India and elsewhere in place of ammoniated tincture of valerian.

Dose, thirty minims to one fluidrachm (1.8–3.75 mils).

TINCTURA VERATRI VIRIDIS. U. S.

TINCTURE OF VERATRUM VIRIDE Tr. Verat. Vir. [Tinctura Veratri, U. S. VIII]

(tĭnc-tū'rą vę-rā-'trī vĭ'rĭ-dĭs)

Tincture of Green Hellebore; Tincture of American Hellebore; Teinture (alcoolé) de Vératre, *Fr.;* Tinctura Veratri, *P. G.;* Nieswurzeltinktur, *G.*

* "Veratrum Viride in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type

Process P (see page 1160), using alcohol as the menstruum." *U. S.*

The U. S. tincture of American hellebore of 1890 was of the same strength as *Norwood's tincture,* which was prepared by its author from fresh drug (240 grains for each fluidounce of alcohol), and was supposed to be saturated. The U. S. P. 1890 tincture was made from dried and powdered veratrum (40 Gm. in 100 mils strength) but was reduced by the U. S. P. VIII from 40 per cent. to 10 per cent. in order that it might conform with the recommendations of the Brussels Congress concerning potent tinctures (see *Tincturæ*). This action has resulted in increasing the use of the fluidextract, which is a better preparation. The U. S. P. IX has returned to the exclusive use of veratrum viride. Veratrum album was also recognized in the U. S. P. VIII.

Dose, of U. S. tincture, ten to thirty minims (0.6–1.8 mils).

TINCTURA ZINGIBERIS. U. S., Br.

TINCTURE OF GINGER Tr. Zingib. [Tincture of Jamaica Ginger]

(tĭnc-tū'ra zĭn-gĭb'ẹ-rĭs)

Teinture (alcoolé) de Gingembre, *Fr. Cod.;* Tinctura Zingiberis, *P. G.;* Ingwertinktur, *G.*

* "Jamaica Ginger, in No. 30 powder, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P (see page 1160), using alcohol as the menstruum. Evaporate 10 Gm. of Tincture of Ginger to dryness in a tared dish on a water bath; the yield of residue does not exceed 2 per cent. When treated with 20 mils of cold distilled water, not more than 15 per cent. of this residue dissolves. Evaporate 10 mils of Tincture of Ginger to dryness in a small flask. Add 5 mils of half-normal alcoholic potassium hydroxide V.S. and boil the mixture gently for thirty minutes under a reflux condenser. Remove the condenser and evaporate the alcohol on a water bath. Then add 50 mils of distilled water to the residue, agitate the mixture, filter it and transfer the aqueous filtrate to a separatory funnel and shake it out with 25 mils of ether. Evaporate the separated ether solution spontaneously by adding it, a few drops at a time, to the center of a watch glass. Cautiously apply the tip of the tongue to the dry residue; the taste should be slightly camphoraceous but not sharp or bitingly-pungent (*capsicum or similar pungent substitute*). It contains about 90 per cent. of $C_2H_5.OH$ by volume." *U. S.*

"Ginger, in No. 40 powder, 100 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Moisten the powder with one hundred millilitres of the Alcohol, and complete the *percolation process.*" *Br.*

The strength of this tincture was reduced at the 1880 revision one-third, to bring it into the 20 per cent. class; this is not a disadvantage, however, in view of the introduction of the fluidextract, and the dose is not now inconveniently large.

The tincture of the British Pharmacopœia is still too weak in the proportion of ginger. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol or proof spirit is apt to be turbid, and the drug is incompletely exhausted of its resinous and oily constituents. Alcohol or rectified spirit is, therefore, properly preferred. Official Jamaica ginger only should be used; for, while a darker-colored preparation is made when the inferior varieties are substituted, the apparent increase in strength is due to coloring matter, and not to the presence of a larger amount of volatile oil or resin.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures in debilitated states of the alimentary canal. It is in this country largely used for the preparation of a syrup of ginger, for which purpose, however, the fluidextract is official, and is better even than the strong tincture of the Br. Pharmacopœia 1885, which was dropped at the 1898 revision.

Dose, eight to forty minims (0.5–2.5 mils).

Off. Prep.—Acidum Sulphuricum Aromaticum, *U. S., Br.*

TINCTURÆ.

TINCTURES

(tĭnc-tū'ræ)

Teintures (Alcooliques) Alcoolés, *Fr.;* Tinkturen, *G.;* Tinture alcooliche, *It.;* Tinturas alcoholicas, *Sp.*

Tinctures, in the pharmaceutical sense of the term, are alcoholic solutions of medicinal substances, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of *ammoniated tinctures* and *ethereal tinctures.* The advantages of alcohol as a menstruum are that it dissolves principles which are sparingly, or not at all, soluble in water, and contributes to their preservation when dissolved, while it leaves behind some inert substances which are dissolved by water. In no instance, however, is dehydrated alcohol employed. Because of the slight amount of water in it, official alcohol dissolves more or less of substances which are insoluble in dehydrated alcohol, while its solvent power in relation to bodies soluble in that fluid is sufficient for all practical purposes. Diluted alcohol or proof spirit is often preferable to official alcohol, as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, while at the same time it is strong enough to prevent spontaneous decomposition. and has the advantages of being cheaper and less stimulating, although a few tinctures when prepared with weak alcoholic menstrua undergo some deterioration in time, in consequence of acetous fermentation taking place in the alcoholic fluid. The best preventive is to keep

them in full and well-closed bottles, at a low temperature. The diluted alcohol of the different Pharmacopœias is not of the same strength; that of the United States consists of equal volumes of official alcohol and water, and has the sp. gr. of about 0.936 at 15.56 C. (60° F.), while the British has four official diluted alcohols—70, 60, 45, and 20 per cent. Alcohol, or rectified spirit, is preferred as a solvent when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but also by exercising an affinity for the alcohol which interferes with its solvent power. Thus, water added to an alcoholic solution of one of these bodies produces a precipitate by abstracting the alcohol from it. Diluted alcohol, or proof spirit, is employed when the substance is soluble both in alcohol and in water; or when one or more of the ingredients are soluble in the one fluid and one or more in the other, as in the case of vegetable bodies which contain extractive or tannin, or the natural salts of the alkaloids, or gum united with resin or volatile oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used. In the preparation of the tinctures, the drug should be dry, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in a moderately fine than in a very fine powder; the proper degree depends, however, upon the ease with which the menstruum extracts the soluble principles. The recommendations of the International Protocol included the use of 70 per cent. alcohol for the various tinctures, but as this has not proven to be the best menstruum for some drugs, the U. S. P. has not always followed the suggestion.

In the U. S. P. IX the general article on tinctures is as follows:

"Tinctures are alcoholic preparations made by extracting the valuable principles from drugs by the use of appropriate menstrua or solvents. Tincture of ferric chloride and tincture of iodine are exceptional, not being made by extraction; they are alcoholic solutions of chemical substances. Tinctures of potent drugs are made of the strength of *ten grammes* [or 154 grains] of drug in *one hundred mils* [or 3 fluidounces, 183 minims] of tincture. The other tinctures vary in the proportion of drug in the finished tincture. Tinctures are made by percolation with few exceptions. Maceration or solution is preferred when from its physical character the drug is not suitable for percolation. The majority of official tinctures are prepared under one or the other of the two type processes described, and in each formula directions are given as to the process to be followed with such modifications as may be necessary. A number of drugs require special manipulation for the preparation of satisfactory tinctures, and for these the formulas in full will be found in the text. Where it has been found possible and desirable to standardize the tinctures a rubric and assay have been added. Tinctures should be stored in tightly-stoppered bottles, kept in a cool place, and protected from light.

Type Process P—Percolation.

"Moisten the powdered drug or mixed drugs designated in the formula with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp, transfer it to a percolator, and, without pressing the powder, allow it to stand well-covered for six hours; then pack it firmly, unless otherwise directed, and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding sufficient of the menstruum to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of finished tincture.

"*Modification for Assayed Tinctures.*—In Tinctures that are directed to be assayed, allow the percolation to proceed until the percolate measures *nine hundred and fifty mils* [or 32 fluidounces, 59 minims]. Assay a sample of this percolate as directed and from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the liquid and add to this enough of the menstruum to make the finished Tincture conform to the required alkaloidal standard.

Type Process M—Maceration.

"Macerate the drug or mixed drugs designated in the formula in a stoppered container, in a moderately warm place, with *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] of the prescribed solvent (unless a different amount is specified in the formula). Continue the maceration with frequent agitation during three days or until the drug is practically extracted, transfer the mixture to a filter and, when the liquid has drained off completely, gradually wash the residue on the filter with enough of the solvent to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of finished tincture." *U. S.*

The British Pharmacopœia in the *Appendix IX* (see Part III) has provided detailed instruction for both percolation and maceration processes.

Tinctures were at one time universally prepared by maceration or digestion. Our own Pharmacopœia formerly directed maceration at ordinary temperatures, and extended the period to two weeks. In several instances in which maceration is ordered in the U. S. Pharmacopœia, maceration for three days is directed, but the Br. process requires seven days. When circumstances require that the tincture should

be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stoppered, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration, and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used until the maceration is completed, when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by expressing it through linen, and filtering.

The plan of preparing tinctures by percolation has been extensively adopted, and has been found to answer well when skilfully executed. In the present edition of our Pharmacopœia, percolation has been adopted as the rule, maceration being directed in some instances in which it was deemed preferable.

The method of making tinctures by diluting fluidextracts, except in a few special cases, is not to be recommended. The menstruum directed for the fluidextract is most frequently not identical with that used for the tincture, and precipitation of active constituents often ensues when this easy method is employed. Owing to the larger dose of the tinctures, and consequently less degree of concentration, a larger proportion of water can be used in their menstrua than in fluidextacts, and this is a distinct advantage, as tinctures are frequently prescribed in combination with aqueous solutions.

Another mode of exhausting medicines by spirit has been proposed by H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks, and thus a current is established, which continues until the solid substance is exhausted or the liquid saturated. During the maceration the bag should be occasionally raised above the surface of the liquor in the bottle, allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. For this mode of preparing tinctures Samuel Gale has proposed the use of a cylindrical stoneware vessel with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the diaphragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm and kept covered with the menstruum.

Tinctures prepared by adding alcohol to the expressed juices of plants have been long in use on the continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England *preserved vegetable juices.* This method of preparing tinctures has, however, been abandoned by both the U. S. and Br. Pharmacopœias. Preserved juices are often energetic, yet it is obvious that tinctures prepared from the fresh plant must be still more so, as they contain necessarily not only the soluble active matter of the juice, but also that which, when the juice is expressed, is left in the solid residue of the plant. For further information see *U. S. D.*, 19th ed., p. 1293.

A process for making tinctures from fresh drugs was official in the U. S. P. VIII. It was deleted from the U. S. P. IX, but introduced into the National Formulary IV under the heading *Tincturæ Medicamentorum Recentium* as follows:

"Tinctures of fresh drugs, when not otherwise directed, are to be prepared according to the following general formula: The Fresh Drug, cut, bruised, or crushed, *five hundred grammes* [or 17 ounces av., 279 grains]; Alcohol, *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Macerate the drug with the alcohol in a closed vessel in a moderately warm place during fourteen days, with occasional stirring; then strongly express the liquid and filter it through paper." *N. F.*

Tinctures should be kept in bottles accurately stoppered, in order to prevent evaporation, which might in some instances be attended with serious inconvenience, by increasing their strength beyond the official standard.

Medicines which act in small doses are most conveniently administered in tinctures, as the proportion of alcohol in which they are dissolved is insufficient to produce an appreciable effect. Those which must be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases, in which the use of tinctures is apt to lead to the formation of habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

In the revision of the Pharmacopœia of 1890, wherever practicable, the proportion of drug to finished tincture was made either 20, 15, 10, or 5 Gm. per 100 mils. Progressive pharmacy demands greater uniformity and simplicity in the processes, and hence in the U. S. P. VIII and IX practically all of the tinctures have been brought into two classes, 20 and 10 Gm. of drug per 100 mils. The potent tinctures, which contained mainly 15 Gm. of drug per 100 mils in the U. S. P. 1890, were reduced to 10 Gm. per 100 mils in order to comply with the recommendations of the Brussels Conference of 1902 for the unification of the strength of Potent Remedies.

A tabulated comparison of the tinctures of the P. G. IV and P. G. V as to sp. gr., extractive percentage and alkaloidal content, is available for those to whom it would be of value in the Yearbook of the *A. Ph. A.*, 1913, p. 84.

TOXITABELLÆ HYDRARGYRI CHLORIDI CORROSIVI. U. S.

POISON TABLETS OF CORROSIVE MERCURIC CHLORIDE Toxitabel. Hydrarg. Chlor. Corr. [Corrosive Sublimate Tablets Bichloride Tablets]

(tŏx-ĭ-tă-bĕl'læ hȳ-drär'gy-rī ċhlō'rĭ-dī cŏr-rǫ-sī'vī)

"Tablets of an angular shape (not discoid), each having the word "POISON" and the skull and cross bones design distinctly stamped upon it. Each tablet weighs about 1 Gm. and contains not less than 0.45 Gm. nor more than 0.55 Gm. of corrosive mercuric chloride ($HgCl_2$); the remainder consisting chiefly of sodium chloride (NaCl). The tablets are to be colored blue, preferably with sodium indigotindisulphonate. Poison Tablets of Corrosive Mercuric Chloride are to be dispensed in securely stoppered glass containers on the exterior of which is placed a red label bearing the word "POISON" and a statement indicating that the Tablets contain the required amount of corrosive mercuric chloride.

"Assay.—Proceed as directed under *Hydrargyri Chloridi Corrosivum,* using one tablet and washing the sulphide with distilled water until the filtrate is colorless and 5 mils of the washings, acidulated with nitric acid, yields no turbidity on the addition of a few drops of silver nitrate T.S. The weight of the mercuric sulphide obtained, multiplied by 1.167, indicates its equivalent in corrosive mercuric chloride. Tablets of Corrosive Mercuric Chloride may also be assayed as directed under the Electrolytic Method (see Part III, Test No. 4). Each tablet shows not less than 0.45 Gm. nor more than 0.55 Gm. of $HgCl_2$." *U. S.*

Uses.—The convenience of tablets of corrosive sublimate for the preparation of antiseptic solutions and their wide use, has led to the introduction of such a tablet into the Pharmacopœia. Because of the large number of cases of poisoning through the inadvertent swallowing of these tablets, in the place of compressed tablets of certain drugs which may have a somewhat similar appearance, it has become highly desirable that these tablets be made in such a form as to render such a mistake less liable. A variety of suggestions for this purpose have been made; among the most popular shapes are the oblong or coffin-shaped, and the triangular tablets. As the solution formed by these tablets is colorless, in order that the solution shall not be confounded with harmless drugs, the tablets are directed to be colored blue by the addition of sodium indigotindisulphonate, or other dye.

A bluish color is greatly preferable to a pink dye, which is sometimes used, not only because it is less liable to be confused with reddish colored drugs but because various confections are often colored red. Despite these precautions, however, it is probable that cases of poisoning by mercuric chloride, either accidental or intentional, will continue to occur from time to time. The physician, therefore, should exercise the greatest reserve in allowing tablets of corrosive sublimate to get into the hands of his patients and the pharmacist should be exceedingly careful in selling and dispensing them. The official tablet contains 0.5 Gm. (8.0 grains) of corrosive sublimate; one of them dissolved in one pint of water (500 mils) makes a solution of 1 to 1000. The addition of sodium chloride in these tablets aids in the solution of the mercuric chloride.

TRAGACANTHA. U. S., Br.

TRAGACANTH Trag. [Gum Tragacanth]

(trăg-ą-căn'thą)

"The spontaneously dried gummy exudation from the stems of *Astragalus gummifer* Labillardière, or from other Asiatic species of *Astragalus* (Fam. *Leguminosæ*)." *U. S.* "Tragacanth is a gummy exudation obtained by incision from Astragalus gummifer, *Labill.,* and some other species of Astragalus. Known in commerce as Syrian tragacanth." *Br.*

Gummi Tragacanthæ vel Astragalorum; Gomme Adragante, *Fr. Cod.*; Tragacantha, *P. G.*; Tragant, Traganth, *G.*; Gomma adragante, Dragante, *It.*; Gomo tragacanto, *Sp.*

Numerous species belonging to this genus yield a gummy matter having the properties of *tragacanth.* The drug known in commerce by that name was at first erroneously supposed to be obtained from *A. Tragacantha* of Linnæus (*A. massiliensis* of Lamarck), which grows in Southern Europe and Northern Africa and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (*A. creticus* of Lamarck) which grows in Crete and Ionia, and on that of Olivier, to *A. verus,* which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer* which he found growing on Mount Libanus in Syria, and from which tragacanth exudes, though not that of commerce. Only recently it has been denied that *Astragalus gummifer* is the source of tragacanth. (*Cons. and Tr. Rep.,* 1910, p. 728.)

Sieber denies that any of the above-mentioned species yields the official tragacanth, which he ascribes to *A. aristatus,* growing in Anatolia, especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the *A. aristatus* of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (Mérat and De Lens.) Lindley received two specimens of plants, said to be those which furnish tragacanth in Turkestan, one of which proved to be *A. gummifer* of Labillardière which was said to yield a white variety, and the other a new species, which he called *A. strobiliferus,* and which was said to yield a red and inferior product. The fact seems to be that the commercial drug is collected from various sources; and it is affirmed that all the species of Astragalus with thorny petioles are capable of producing it. These form a natural group, and so closely resemble one another that botanists have found some difficulty in distinguishing them. They are very abundant on the mountains of Asia Minor, and, according

to information received by M. J. Léon Soubeiran from Balansa, a scientific traveller who derived his knowledge from personal observation, the gum-producing species are closely analogous to the *A. creticus* of Lamarck. It is in the Anti-Taurus range that the gum is chiefly collected. Transverse incisions are made, near the base of the stem, into the medullary tissues, which alone yield the gum. This exudes very slowly, flowing at night, and ceasing during the day; two weeks usually elapse before the pieces are large enough for collection. The shape of the pieces is influenced by the rapidity of the exudation, and the lines on their surface indicate the daily concretion. The section Tragacantha of the genus Astragalus includes the principal species which yield gum tragacanth.

According to Haussknecht, tragacanth is yielded by the following species of Astragalus: *A. adscendens* Boiss. et Haussk. (Southern Persia); *A. leioclados* Boiss. (in Middle and Western Persia, by Ispahan and Hamadan); *A. brachycalyx* Fisch. (Kurdistan and Luristan); *A. gummifer* Labill. (widely distributed from Lebanon to Armenia and in the northern regions of the Euphrates and Tigris); *A. microcephalus* Willd. (the same as *A. gummifer* Labill., and also in Asia Minor); *A. pycnocladus* Boiss. et Haussk. (particularly in Western Persia); *A. stromatodes* Bge. (in Achyr Dagh, in Northern Syria); *A. kurdicus* Boiss. (Aintab). Other species that yield a tragacanth gum are *A. heratensis* Bge., of the Khorasan Mountains, which yields a gum known as "kutira," and *A. Parnassi* Boiss., var. *cyllenea*, found on the mountains of Peloponnesus.

Harris states that the best Smyrna tragacanth is produced in Asia Minor. It is not, however, collected in the immediate vicinity of Smyrna, but comes from Karahissar, Jalowadsch, and even farther in the interior, where the plant grows wild. This kind of gum consists of white, yellow, and red, hardened pieces, which have become congealed after oozing out of the bush or tree in the hot sun of a Levantine summer. The gum is secured in a similar manner as opium by an incision in the branch. This is done in the spring and summer of each year, and the gum is usually scraped in September, when the first rains begin to fall. During the last twenty years the gum tragacanth trade of Smyrna has decreased. It has been estimated that the trade has fallen from 600,000 pounds to 55,000 pounds in that length of time. (*Oil, Paint and Drug Reporter*, lxxiii, p. 633.)

Properties.—Tragacanth is odorless and nearly tasteless. It occurs either in flaky, leaf-like pieces, irregularly oblong or roundish, or in tortuous vermicular filaments, rounded or flattened, rolled up or extended, of a whitish, yellowish-white, or slightly reddish color, marked by parallel lines or ridges, somewhat translucent, and resembling horn in appearance. In commerce certain varieties of tragacanth are recognized and usually known by the name of the locality from which they have been produced or through which they have entered commerce. The ordinary tragacanth, tragacanth in sorts, sometimes known as *traganton*, occurs in irregular pieces; Smyrna tragacanth appears usually in broad thick flakes, yellowish or brownish; Syrian tragacanth, in thin, ribbon-like, white flakes, is said really to be obtained in Kurdistan and Persia. Tragacanth is officially described as "in flattened, lamellated fragments varying from ribbon-shaped bands to long and linear pieces, which may be either straight or spirally twisted, and from 0.5 to 2.5 mm. in thickness; whitish to light brown in color, translucent and horny; fracture short; rendered more easily pulverizable by heating to 50° C. (122° F.); inodorous; taste insipid, mucilaginous. Under the microscope, sections made from Tragacanth, previously softened in water, and mounted in glycerin, show the lamellæ of mucilaginous walls and a few starch grains, the latter being mostly spherical and single, occasionally 2- to 3-compound, the individual grains from 0.003 to 0.025 mm. in diameter and colored blue with iodine. Indian Gum, derived from plants of uncertain origin, upon similar treatment and examination, shows numerous threads of a granular substance, sometimes the hyphæ of a fungus and chains of bacteria, and occasional fragments of a yellowish-brown or reddish-brown color, containing lignified wood-fibers, a few rosette aggregates of calcium oxalate, from 0.02 to 0.03 mm. in diameter, and a few spherical starch grains, from 0.003 to 0.007 mm. in diameter. Add 1 Gm. of Tragacanth to 50 mils of distilled water; it swells and forms a smooth, nearly uniform, stiff, opalescent mucilage free from cellular fragments. Indian Gum upon similar treatment forms an uneven mucilage containing a few reddish-brown fragments, and on stirring separates in the form of coarse, uneven strings. Shake 2 Gm. of Tragacanth with 100 mils of water until fully swollen and free from lumps, and then add 2 Gm. of powdered sodium borate and shake the mixture thoroughly until the salt is dissolved; the mucilage does not lose its transparency, nor exhibit any change in consistence, and on pouring is not slimy or stringy, even after standing twenty-four hours (*foreign gums*). Boil 1 Gm. of Tragacanth with 20 mils of water until a mucilage is formed, then add 5 mils of hydrochloric acid and again boil the mixture for five minutes; it develops no pink or red color (*Indian Gum*). The powder is whitish; forming with water a translucent mucilage and under the microscope exhibiting numerous starch grains, from 0.003 to 0.025 mm. in diameter, varying from spherical to elliptical, with occasional 2- to 4-compound grains, many of the grains being swollen and more or less altered, due to the drying of the Tragacanth before powdering. Powdered Indian Gum shows numerous fragments of lignified vegetable tissue. Tragacanth yields not more than 3.5 per cent. of ash." *U. S.*

"Thin flattened flakes, irregularly oblong, or more or less curved, marked on the surface by concentric ridges. Frequently two and a half

centimetres long, and twelve millimetres wide. White or pale yellowish-white, somewhat translucent. Horny, fracture short. Inodorous; almost tasteless. Sparingly soluble in *water,* but swelling into a gelatinous mass, which may be tinged violet or blue by *N/10 solution of iodine.* Ash not more than 4 per cent." *Br.*

It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar at the temperature of 50° C. (122° F.). Its sp. gr. is 1.384. Introduced into water, it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum arabic, the other swelling in water, but not dissolving. To separate the soluble from the insoluble part requires agitation with separate portions of water; the solutions are to be decanted and filtered, and the process is to be continued until water ceases to dissolve anything.

Von Sandersleben reported the discovery that when heated with dilute acids tragacanth acquired reducing properties, and formed, along with much syrup, *arabinose,* which crystallized. (Tollens, *Handbuch der Kohlenhydrate,* 1888, 218.) The explanation of this observation, now generally accepted, is that in tragacanth, like some other gums, part of the arabic acid is present in soluble form, mostly combined with bases, while another part is present in insoluble form, and is known as *traganthin.* This latter, however, under the influence of certain enzymes, is converted into the soluble form. (Lippmann, *Chemie der Zuckerarten,* 2te Auf., 1895, 925.) C. O'Sullivan states that tragacanth consists of cellulose, the portion insoluble in boiling water, cold dilute acids, and alkalies; also *soluble gum,* yielding a series of gum acids of the nature of *geddic acid,* and which are called *polyarabinon-trigalactan-geddic acids;* starch granules; bassorin, which yields *a-tragacanthan-xylan-bassoric acid, xylan-bassoric acid* and *bassoric acid.* (*Proc. Chem. Soc.,* 1901.) Examined by Kützing by means of the microscope, tragacanth was found to consist of organized cells. (See *A. J. P.,* xxv, 37.) In conformity with this statement is the remarkable fact, discovered by Hugo von Mohl and confirmed by Wigand, that tragacanth is not a secretion of the plant, but the result of the transformation of the cells of the pith and those of the medullary rays which traverse the ligneous part of the stem and older branches. (*A. J. P.,* xxxi, 243.)

It is stated by S. H. Maltass that tragacanth is adulterated, in the Levant, with worthless gums brought from Armenia and Caramania, which, as they are originally of a dark color and destitute of the flaky form of the genuine gum, are broken into small fragments and whitened by means of lead carbonate before being mixed with the tragacanth. Hanbury states, in confirmation of this, that he has detected lead in the *small tragacanth* imported into London. (*P. J.,* xv, 20.) Gum tragacanth has been recently admixed with and substituted by Indian gum, the product of *Cohlospermum gossypium* (Fam. *Bixaceæ*). This occurs in vermiform or rounded tears having a dull, rough surface. It is detected by the official tests. The powdered drug is not only adulterated with the Indian gum, but with powdered acacia, dextrin, wheat and cornstarch. Payet gives a test for the detection of acacia in powdered tragacanth which depends on the brown color produced by the oxidase of the former when brought in contact with an aqueous solution of guaiacol in the presence of hydrogen dioxide. (*Ann. de Chim. Analyt.,* x, p. 63.)

Uses.—Tragacanth is demulcent, but, on account of its difficult solubility, is not often given internally. The great viscidity which it imparts to water renders it useful for the suspension of heavy insoluble powders, and it is also employed in pharmacy to impart consistence to troches, for which it answers better than does gum arabic, and in making emulsions, although for these purposes it is inferior to acacia. It is also used for its demulcent action in *pharyngitis* by allowing a piece of the gum to dissolve slowly in the mouth. It is officially employed as the basis of many of the troches.

TRINITROPHENOL. U. S. (Br.)

TRINITROPHENOL Trinitrophen. [Picric Acid]

(trī-nī-trō-phē′nŏl)

"Trinitrophenol [$C_6H_3O_7N_3$ or $C_6H_2(OH)(NO_2)_3$ 1 : 2 : 4 : 6 = 229.05]. Preserve it in well-stoppered bottles, in a cool place, remote from fire.

"*Caution.*—For safety in transportation it is usually mixed with about 20 per cent. of water. Before applying the tests described below, dry the Trinitrophenol to constant weight in a desiccator over sulphuric acid." *U. S.* "Picric Acid may be obtained by the action of nitric acid and sulphuric acid on phenol, and contains not less than 99 per cent. of tri-nitro-phenol, $C_6H_2(NO_2)_3OH$." *Br.*

Acidum Picricum, *Br.;* Acidum Picricum; Carbazotic Acid; Trinitrophenol; Nitrophenic Acid, C_6H_2.

It is obtained by the action of nitric acid on indigo, silk, leather, wool, aloes, benzoin, Australian gum, and other substances, or, as the name indicates, from phenol (carbolic acid). It may be cheaply prepared by adding coal tar creosote (impure phenol) gradually to strong nitric acid and heating, when, on standing, the picric acid will crystallize out; but in practice it is now almost always made by dissolving crys-

tallized phenol in strong sulphuric acid, and adding either nitric acid or sodium nitrate to the resultant phenolsulphonic acid. The reaction is as follows:

$$C_6H_5OH + H_2SO_4 = C_6H_4OH.HSO_3 + H_2O$$
$$C_6H_4OH.HSO_3 + 3HNO_3 = C_6H_2OH(NO_2)_3 + H_2SO_4 + 2H_2O$$

It is in pale yellow shining scales, fusing at 122.5° C. (252.5° F.) and subliming undecomposed. It is soluble in water, to which it gives a strong yellow color and very bitter taste. Its salts crystallize readily, and explode when heated. The potassium salt is so sparingly soluble that an alcoholic solution of the acid may be used as a test for this alkali. It is largely used in dyeing, producing magnificent yellow colors, and, in connection with indigo or Prussian blue, different shades of green. The salts which picric acid forms with potassium and sodium are yellow and bitter, and are much used in the arts. They are, however, violent explosives, and as such have produced very serious consequences. Picric acid itself it also a powerful explosive which is used in modern warfare, not as a propellant, but as the exploding charge in shells, a detonator being necessary to explode it. A saturated aqueous solution of picric acid is a very delicate test for albumin. (See *Esbach's Reagent,* Part III.) *Ammonium picrate* is universally preferred for internal use. It crystallizes in rhombic scales, which are somewhat more soluble than the corresponding potassium salt.

"Trinitrophenol occurs in pale yellow, rhombic prisms or scales; odorless, and having an intensely bitter taste. It explodes when heated rapidly and when subjected to percussion. One Gm. of Trinitrophenol dissolves in 78 mils of water, 12 mils of alcohol, 35 mils of chloroform, 65 mils of ether, and in 10 mils of benzene at 25° C. (77° F.); also in 15 mils of boiling water. An aqueous solution of Trinitrophenol is acid to litmus. It melts between 121° and 123° C. (249.8° and 253.4° F.). An aqueous solution of Trinitrophenol (1 in 100) has a yellow color, which becomes darker on the addition of alkalies, and red on the addition of ammonium sulphide T.S. or a solution of an alkaline cyanide. Add a few drops of barium chloride T.S. to 10 mils of an aqueous solution of Trinitrophenol (1 in 100); the liquid does not at once become opalescent (*sulphate*). Dissolve 2 Gm. of Trinitrophenol in 50 mils of benzene, collect the insoluble residue, if any, on a small filter which has been dried at 100° C. (212° F.) and weighed. Wash the residue and filter with benzene until the washings are colorless. The residue, dried at 100° C. (212° F.), does not exceed 0.2 per cent." *U. S.*

"Bright yellow crystalline powder. Inodorous; taste very bitter. Soluble in 90 parts of *water,* and in 10 parts of *alcohol* (90 per cent.), forming intensely yellow solutions which stain the skin yellow. Melting point 122° C. (251.6° F.). 2 grammes dissolved in hot *water* require for neutralisation 17.3 millilitres of *N/2 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator." *Br.*

Uses.—Trinitrophenol is germicidal, astringent, and apparently stimulates epithelial growth. According to Ehrenfried (*J. A. M. A.,* 1911, lvi, p. 412), a saturated aqueous solution (1.2 per cent.), destroys the *Bacillus pyocyaneus* in less than one minute and the *Staphyloccocus pyogenes aureus* in two minutes, while in the experiments of Schamberg and Kolmer (*L. L.,* 1911, ii, p. 1397) it showed itself four times as active as phenol. Internally trinitrophenol is comparatively feeble in its effects upon the system. It is absorbed probably as a sodium salt and eliminated chiefly through the urine to which it imparts an intense yellow color. After large doses the skin and mucous membranes are also stained yellow. In toxic quantities it causes in the lower animals destruction of the red blood corpuscles, but this effect has not been reported in man. The symptoms of poisoning as observed in human beings have been vomiting, diarrhea, the matters ejected being stained yellow, strangury and often anuria; in severe cases stupor with convulsions followed by collapse have also been noted. A very common symptom even after not extremely large doses is itching of the skin frequently associated with an eczematous eruption. Ehrenfried states that there is no fatal case of picric acid poisoning upon record, but 15 to 30 grains are sufficient to cause toxic symptoms. It should be remembered that the drug may be absorbed after its local application in sufficient quantities to produce constitutional effects.

Internally picric acid has been used in the treatment of *trichinosis* and *malaria,* but is probably without any value. It is capable of destroying intestinal parasites either *tapeworm* or *roundworm,* but has no advantage over other vermifuges. The practical value of trinitrophenol in medicine is as a local agent. While by some used as an antiseptic dressing for superficial *wounds,* it is especially prized in *burns* of the first and second degree and is also useful for its astringent and antiseptic action in *ulcers* with free discharge. Wilcox (*Archives of Pedriatics,* 1913, xxx) recommends it very highly in the treatment of various skin diseases, especially acute *eczema, intertrigo,* and *herpes labialis.* In local *hyperidrosis,* especially of the feet, it has long been recognized as a standard remedy. Picric acid is also highly recommended by a number of ophthalmologists in the treatment of *injuries of the cornea,* due to caustic agents, such as quick-lime and the mineral acids. It has also been employed in simple *conjunctivitis* and in *trachoma.* For the latter purpose Ohlemann (*Wochens. f. Ther. u. Hyg. d. Auges,* 1910, p. 103) recommends a 2 per cent. ointment which is applied directly to the lid, after previous cocainization if necessary.

For surgical purposes from one-half to one per cent. is generally used. In skin diseases the aqueous solution may be either painted over the lesion or sometimes gauze moistened with the

solution applied. In sweating feet a dusting powder containing 2 per cent. of picric acid with talc is sometimes used. The great drawback of the remedy is its powerful staining properties.

In skin diseases when the epiderm is unbroken it may be desirable to use stronger solutions in which case a hydro-alcoholic menstruum is employed.

Picric acid poisoning is quite common among workers engaged in the manufacturing of high explosives. In some cases this is manifested by dermatitis, often quite severe and resistant to treatment. The inflammation of the skin in these cases bears a strong resemblance to that seen in ivy poisoning and at times is accompanied with marked constitutional disturbances, such as headache, loss of appetite, nose bleed, and fever. There is in many of these cases more or less leukocytosis. In other patients the symptoms are chiefly gastro-intestinal; abdominal cramps, diarrhea, vomiting and headache being the most common manifestations. The inhalation of the dust by these workers produces a bronchitis accompanied with a dry hacking cough, often with expectoration of blood, and signs of irritation of the throat.

Dose, one-half to one grain (0.032–0.065 Gm.).

TRITICUM. U. S. (Br.)

TRITICUM Tritic. [Couch Grass Dog Grass]

(trĭt'ĭ-cŭm)

"The dried rhizome and roots of *Agropyron repens* (Linné) Beauvois (Fam. *Gramineæ*), gathered in the spring." *U. S.* "Couch Grass is the dried rhizome of Agropyron repens, *Beauv.*, freed from remains of leaves and rootlets." *Br.*

Agropyrum, *Br.;* Rhizoma Graminis; Radix Graminis; Quick-grass, Quitch, Scotch-grass, Twitch-grass, Witch-grass, Quickens; Chiendent officinal ou Petit chiendent, *Fr. Cod.;* Queckenwurzel, Grasswurzel, *G.;* Grama (Rizoma de), *Sp.*

This grass, originally a native of Europe, now abounds in meadows and cultivated grounds in the Northern United States, where it is often very troublesome as a weed. It is specifically characterized by its creeping rootstock, the leaves being flat, thin and finely veined, and the flowering glumes being glabrous or scabrous. It is probable that the rhizome of a number of other grasses share the medicinal properties of *Agropyron repens.* Of these the Scotch or Bermuda grass, *Capriola Dactylon* (L.) Kuntze, is probably as effective as the official species.

Much spurious triticum has appeared upon the market recently. Most of it can be readily distinguished from the official drug by the presence of starch in the spurious article.

Properties.—Triticum is officially described as follows: "Usually in pieces from 4 to 12 mm. in length and from 1 to 2.5 mm. in diameter; externally light yellow or yellowish-brown, longitudinally furrowed, smooth, lustrous, nodes with circular leaf-scars, a few root-scars and occasional slender roots; fracture tough, fibrous; internally lemon-yellow and with a large, hollow pith; odor slight, aromatic; taste sweetish. Roots filiform, irregularly branching, attaining a length of about 5 cm. and not more than 0.5 mm. in thickness, light brown or yellowish-brown, frequently covered with long root hairs. Under the microscope, transverse sections of Triticum show a single layer of strongly lignified epidermal cells; a hypodermis of from 3 to 6 rows of more or less polygonal cells with strongly lignified walls; a cortex of from 10 to 16 rows of thin-walled parenchyma cells, occasionally with nearly spherical starch grains about 0.005 mm. in diameter, or with irregular masses of a more or less soluble carbohydrate; among the parenchyma cells and near the hypodermis occur small, widely separated fibro-vascular bundles, each with a closed sheath of sclerenchymatous fibers; an endodermis, the lateral and inner walls of the cells moderately thickened, strongly lignified and somewhat porous; several layers of sclerenchymatous fibers immediately inside the endodermal ring, in which are imbedded an interrupted circle of collateral fibro-vascular bundles having large tracheæ; adjoining these are usually 8 to 10 rows of parenchyma cells with a few fibro-vascular bundles and a pith in which the parenchyma cells are more or less broken or absent. The powder is light yellowish; consisting of irregular, lignified fragments; numerous fragments showing tracheæ with annular or spiral thickenings or marked with simple pores and associated with long, narrow, rather thin-walled, strongly lignified sclerenchymatous fibers; fragments of epidermis made up of cells rectangular in outline, the longer walls considerably thickened, strongly lignified and marked with numerous transverse pores; ends of epidermal cells usually separated from each other by a very narrow cell with thin walls and few pores; numerous fragments of parenchyma rectangular in outline and with thin, porous walls. Triticum yields not more than 3 per cent. of ash." *U. S.*

"Rhizome pale yellow, rigid, from two to two and a half millimetres in diameter, usually in pieces from three to six millimetres long. Strongly furrowed longitudinally, hollow except at the nodes. Contains no starch. No odor; taste slightly sweet." *Br.*

The morphology of triticum has been described by Holm (*M. R.,* xix, p. 65). Kebler reports (*A. J. P.,* 1909, p. 75) the adulteration of triticum with Bermuda grass, by which he means probably *Capriola Dactylon* (L.) Kze., a grass which is naturalized in the United States from Europe and apparently widely distributed.

The Austrian Pharmacopœia has a requirement of not less than 30 per cent. of aqueous extractive for this drug.

Uses.—Triticum is never exhibited for the purpose of affecting the general system, but only for its influence upon the genito-urinary organs. It is much used by some surgeons in *irritable bladder,* and also in *cystitis.* It is one of the least stimulant of the remedies of its class, and may be employed very freely. In Europe its decoction is said to be used to a

considerable extent as a diluent and slightly nutritious drink. It may be taken *ad libitum*, or the fluidextract may be given in doses of a fluidrachm (3.75 mils) every three hours in five or six ounces of water.

Off. Prep.—Fluidextractum Tritici, *U. S.;* Decoctum Agropyri, *Br.;* Extractum Agropyri Liquidum, *Br.*

TRITURATIO ELATERINI. U. S.

TRITURATION OF ELATERIN

(trĭt-ū-rā′tĭ-ō ĕl-ą-tę-rī′nī)

Pulvis Elaterini Compositus, *Br.*, 1898; Compound Powder of Elaterin; Trituration d'Elatérine, *Fr.;* Elaterintrituration, *G.*

* "Elaterin, *ten grammes* [or 154 grains]; Sugar of Milk, in moderately fine powder, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix them thoroughly by trituration (see *Triturationes*)." *U. S.*

The Br. Pharm., 1898, included Compound Powder of Elaterin, which was identical with the Trituration of Elaterin, except in strength; the U. S. P. trituration contains 10 per cent. of elaterin, the British powder 2½ per cent. It is not recognized by the Br. 1914.

This is probably the best representative of the class of triturations that could be selected for introduction into the national authority. Elaterium is at best a substance of variable quality, while the active principle is a definite product, and accurate dosage can be secured more effectually through the use of this trituration than by the employment of commercial elaterium.

Dose, from one-fourth to one grain (0.016–0.065 Gm.).

TRITURATIONES. U. S.

TRITURATIONS

(trĭt-ū-rā-tĭ-ō′nēȿ)

Triturations, *Fr.;* Triturationen, *G.*

"Unless otherwise directed, Triturations are to be prepared according to the following formula. * Take of the Substance, *ten grammes* [or 154 grains]; Sugar of Milk, in moderately fine powder, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Weigh the substance and the sugar of milk separately; then place the substance, previously reduced, if necessary, to a moderately fine powder, in a mortar; add about an equal measure of sugar of milk, mix well by means of a spatula, and triturate the powders thoroughly together. Then add fresh portions of the sugar of milk, from time to time, until the whole is added, and continue the trituration after each addition until the substance is intimately mixed with the sugar of milk and reduced to a fine powder." *U. S.*

This general formula has been introduced into the Pharmacopœia in order that a definite and uniform method be authorized of making a class of powders which has come into use in various sections of our country. While the necessity of giving recognition to the class may be questioned by many, the importance of securing uniformity in composition is evident.

TROCHISCI.

TROCHES

(trǫ-ȼhĭs′cī)

Tabellæ; Lozenges; Tablettes, *Fr. Cod.;* Pastilli, Rotulae, *P. G.;* Pastillen, Plätzchen, Tabletten, *G.;* Pastiglie, *It.;* Tabletas, *Sp.*

Troches or *lozenges* are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed to be held in the mouth and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in large quantities and which are destitute of any very disagreeable flavor.

Lozenges were formerly much more used and more skilfully prepared in Europe than in this country, but at present those manufactured here are fully equal to the imported lozenges. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues.* A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the mass is rendered uniform by a frame upon which the ends of the roller rest. The upper surface is now dusted with sugar and starch, and the mass is divided into small cakes by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in boxes. Lozenges may be prepared from almost any medicine which it is advisable to administer in this form. The following typical formula may be found useful.

Take citric acid, in powder, a drachm; powdered sugar eight ounces; oil of lemon twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. Lozenges are sometimes made by saturating blank lozenges with aromatic spirits. Currant paste or jelly has come into use of late years largely as a basis for troches. For formulas for lozenges with currant paste basis, see *U. S. D.*, 19th edition, page 1297.

Lozenges of a cylindrical shape are extensively used, having a basis of licorice, gum, and sugar, and the manufacture of these is now an important industry. Franklin C. Hill devised an improved machine for making Licorice and

Wistar's Lozenges. (See *A. J. P.*, 1874, 401.) For Slocum's and Harrison's improved forms of lozenge boards, rollers, etc., see *A. J. P.*, 1879, 589; 1880, 255. A. D. Marcy figured an instrument for shaping troches in *N. R.*, Feb., 1882.

The Br. Pharmacopœia, 1914, adopted four bases for lozenges, as follows: fruit basis, rose basis, simple basis, and tolu basis. It will be noticed that in the British formulas the quantity of active ingredients for each lozenge is stated and the kind of basis indicated. This is done merely to avoid repetition.

PREPARATION WITH FRUIT BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge. Mix it with 6.5 grammes of Tragacanth and 26 grammes of Refined Sugar, both in fine powder. Add sufficient of the black-currant paste of commerce to produce 650 grammes, beat into a uniform mass, divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." *Br.*

PREPARATION WITH ROSE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge. Treat it as described under 'Preparation with Simple Basis,' previously mixing with the Refined Sugar 0.025 millilitre of Oil of Rose." *Br.*

PREPARATION WITH SIMPLE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge, mix it with 496 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Make the mixture into a paste with 35 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water, divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." *Br.*

PREPARATION WITH TOLU BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; dissolve such salts of alkaloids as may be ordered in 10 millilitres of Distilled Water; mix the solution with 482 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Incorporate 10 millilitres of Tincture of Balsam of Tolu, and any other drugs ordered for the lozenges. Make into a paste with 35.5 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water; divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." *Br.*

TROCHISCUS ACIDI BENZOICI. Br.

BENZOIC ACID LOZENGE

(trō-ĸĭs'cŭs ăç'ĭ-dī bĕn-zō'ĭ-cī)

Tablettes de l'Acide Benzoique, *Fr.*; Benzoesäurepastillen, *G.*

"Benzoic Acid, 0.03 *gramme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.*

This is a stimulant and antiseptic lozenge useful in *chronic pharyngitis,* and other passive congestions of the buccal cavity.

TROCHISCUS ACIDI CARBOLICI. Br.

PHENOL LOZENGE

(trō-ĸĭs'cŭs ăç'ĭ-dī căr-bŏl'ĭ-cī)

Tablettes de l'Acide Phénique, *Fr.*; Phenolpastillen, *G.*

"Phenol, in powder, 15 *grammes;* Refined Sugar, in powder, 500 *grammes;* Gum Acacia, in powder, 45 *grammes;* Tragacanth, in powder, 15 *grammes;* Lemon Juice, 45 *millilitres.* Mix. Divide into five hundred lozenges. Dry them in a hot-air chamber at a moderate temperature. Each lozenge contains 0.03 gramme of Phenol, or approximately one-half grain. It is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This lozenge affords an excellent means of obtaining the antiseptic and local anodyne effect of phenol in *acute pharyngitis, stomatitis,* and similar infections of the mouth and throat.

TROCHISCI ACIDI TANNICI. U. S. (Br.)

TROCHES OF TANNIC ACID Troch. Acid. Tann.

(trō-ĸĭs'cī ăç'ĭ-dī tăn'nĭ-cī)

Trochiscus Acidi Tannici, *Br.*, Tannic Acid Lozenge; Tannin Lozenges; Tablettes de Tannin, *Fr.*; Tanninpastillen, *G.*

* "Tannic Acid, *six grammes* [or 92.5 grains]; Sugar, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains]; Tragacanth, in fine powder, *two grammes* [or 31 grains]; Stronger Orange Flower Water, *a sufficient quantity,* to make *one hundred troches.* Rub the powders together until they are thoroughly mixed; then form a mass with stronger orange flower water, and divide it into *one hundred troches.*" *U. S.*

"Tannic Acid, 0.03 *gramme.* Mix with the *Tolu Basis* to form a Lozenge." *Br.* (See above.)

These are useful in *relaxation of the uvula,* and in *chronic angina,* being allowed slowly to dissolve in the mouth. Each U. S. troche contains about one grain (0.065 Gm.) of the acid; the Br. about half a grain (0.032 Gm.).

TROCHISCI AMMONII CHLORIDI. U. S.

TROCHES OF AMMONIUM CHLORIDE Troch. Ammon. Chlor.

(trō-ĸĭs'cī ăm-mō'nĭ-ī ĸlō'rĭ-dī)

Tablettes de Chlorhydrate d'Ammoniaque, *Fr.*; Chlorammoniumpastillen, *G.*

* "Ammonium Chloride, in fine powder, *ten grammes* [or 154 grains]; Extract of Glycyrrhiza, in fine powder, *twenty grammes* [or 308.6 grains]; Tragacanth, in fine powder, *two grammes* [or 31 grains]; Sugar, in fine powder, *forty grammes* [or 1 ounce av., 180 grains]; Syrup of Tolu, *a sufficient quantity,* to make

one hundred troches. Rub the powders together until they are thoroughly mixed; then, form a mass with syrup of tolu, and divide it into *one hundred troches.*" *U. S.*

Each troche contains about one and a half grains (0.096 Gm.) of ammonium chloride.

These troches are largely used in *congested conditions of the pharynx and larynx.*

TROCHISCUS BISMUTHI COMPOSITUS. Br.

COMPOUND BISMUTH LOZENGE

(trō-ghĭs'cŭs bĭs-mū'thī cŏm-pŏs'ĭ-tŭs)

Troches of Bismuth; Tablettes de Sous-nitrate de Bismuth, *Fr. Cod.*; Bismuthpastillen, *G.*

"Bismuth Oxycarbonate, 0.15 *gramme;* Heavy Magnesium Carbonate, 0.15 *gramme;* Precipitated Calcium Carbonate, 0.30 *gramme.* Mix with the *Rose Basis* to form a Lozenge." *Br.* (See p. 1168.)

These may be used to obtain the effects of bismuth subcarbonate on the stomach, as well as of the magnesium and calcium carbonates as an antacid, two or more being administered for a dose. They may also be found useful in *chronic inflammation of the throat and œsophagus.*

TROCHISCUS CATECHU. Br.

CATECHU LOZENGE

(trō-ghĭs'cŭs că'tē-chū)

"Catechu, 0.06 *gramme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.*

This lozenge was introduced into the Br. Pharm., 1914. It is mildly astringent.

TROCHISCI CUBEBÆ. U. S.

TROCHES OF CUBEB Troch. Cubeb.

(trō-ghĭs'cī cū-bē'bæ)

Tablettes de Cubèbe, *Fr.*; Kubebenpastillen, *G.*

* "Oleoresin of Cubeb, *two grammes* [or 31 grains]; Oil of Sassafras, *one mil* [or 16 minims]; Extract of Glycyrrhiza, in fine powder, *twenty-five grammes* [or 386 grains]; Acacia, in fine powder, *twelve grammes* [or 185 grains]; Syrup of Tolu, *a sufficient quantity,* to make *one hundred troches.* Rub the powders together until they are thoroughly mixed; then add the oleoresin and the oil, and incorporate them with the mixture. Lastly, form a mass with syrup of tolu, and divide it into *one hundred troches.*" *U. S.*

Each lozenge contains one-third of a grain (0.021 Gm.) of the oleoresin of cubeb, being about one-fourth the strength of the lozenge of 1870, and one-half the strength of the 1890 troches. The preparation is intended chiefly for effect upon the fauces and other parts of the upper alimentary passages, and may be used advantageously in some cases of *chronic cough,* and in *ulceration* or *chronic inflammation of the fauces.*

TROCHISCUS FERRI REDACTI. Br.

REDUCED IRON LOZENGE

(trō-ghĭs'cŭs fĕr'rī rē-dăc'tī)

Tablettes de Fer Réduit par l'Hydrogène, Tablettes de Fer, *Fr.*; Eisenpastillen, *G.*

"Reduced Iron, 0.06 *gramme.* Mix with the *Simple Basis* to form a Lozenge." *Br.* (See p. 1168.)

From one to three of the lozenges may be taken for a dose.

TROCHISCUS GUAIACI RESINÆ. Br.

GUAIACUM RESIN LOZENGE

(trō-ghĭs'cŭs guaĭ'ă-cī rē-sĭ'næ)

Tablettes de Résine de Gayac, *Fr.*; Guajakharzpastillen, *G.*

"Guaiacum Resin, 0.2 *gramme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.* (See p. 1168.)

TROCHISCUS IPECACUANHÆ. Br.

IPECACUANHA LOZENGE

(trō-ghĭs'cŭs ĭp-ē-căc-ū-ăn'hæ)

Tablettes d'Ipécacuanha, *Fr. Cod.*; Brechwurzelpastillen, *G.*; Pastiglie d'ipecacuana, *It.*

"Ipecacuanha Root, in powder, 0.015 *gramme.* Mix with the *Simple Basis* to form a Lozenge." *Br.* (See p. 1168.)

These are useful expectorant lozenges in *catarrhal complaints.*

TROCHISCUS KINO EUCALYPTI. Br.

EUCALYPTUS KINO LOZENGE

(trō-ghĭs'cŭs kī'nō eū-că-lŷp'tī)

Eucalyptus Gum Lozenge, Red Gum Lozenge; Tablettes de Kino d'Eucalypte, *Fr.*; Eucalyptuskinopastillen, *G.*

"Eucalyptus Kino, 0.06 *gramme.* Mix with the *Fruit Basis* to form a lozenge." *Br.* (See p. 1168.)

TROCHISCUS KRAMERIÆ. Br.

KRAMERIA LOZENGE

(trō-ghĭs'cŭs krą-mē'rĭ-æ)

Krameria Lozenge, Rhatany Lozenge; Tablettes de Ratanhia, *Fr.*; Ratanhiapastillen, *G.*

"Extract of Krameria, 0.06 *gramme.* Mix with the *Fruit Basis* to form a Lozenge." *Br.* (See p. 1168.)

These are astringent troches, which may be used in *chronic angina.*

TROCHISCUS KRAMERIÆ ET COCAINÆ. Br.

KRAMERIA AND COCAINE LOZENGE

(trō-ghĭs'cŭs krą-mē'rĭ-æ ĕt cō-cą-ĭ'næ)

Rhatany and Cocaine Lozenge; Tablettes de Ratanhia et de Cocaine, *Fr.*; Ratanhia- und Cocain-pastillen, *G.*

"Extract of Krameria, 0.060 *gramme;* Cocaine Hydrochloride, 0.003 *gramme.* Mix with

the *Fruit Basis* to form a Lozenge. This Lozenge contains 0.003 gramme of Cocaine Hydrochloride, or approximately 1/20 grain." *Br.* (See p. 1168.)

TROCHISCUS MORPHINÆ. Br.

MORPHINE LOZENGE

(trō-ḳĭs'cŭs mör-phĭ'næ)

Tablettes de Chlorhydrate de Morphine, Tablettes de Morphine, *Fr.;* Morphinpastillen, *G.*

"Morphine Hydrochloride, 0.002 *gramme.* Mix with the *Tolu Basis* to form a Lozenge. This Lozenge contains 0.002 gramme of Morphine Hydrochloride, or approximately 1/32 grain." *Br.* (See p. 1168.)

This is an undesirable preparation, as the local action of morphine is insignificant. Any sedative effect in *cough* will be due to the systemic absorption of the drug.

TROCHISCUS MORPHINÆ ET IPECACUANHÆ. Br.

MORPHINE AND IPECACUANHA LOZENGE

(trō-ḳĭs'cŭs mör-phĭ'næ ĕt ĭp-ē-căc-ū-ăn'hæ)

Tablettes de Morphine et d'Ipécacuanha, *Fr.;* Morphinpastillen mit Brechwurzel; Morphin- und Brechwurzel-pastillen, *G.*

"Morphine Hydrochloride, 0.002 *gramme;* Ipecacuanha Root, in powder, 0.006 *gramme.* Mix with the *Tolu Basis* to form a Lozenge. This Lozenge contains 0.002 gramme of Morphine Hydrochloride, or approximately 1/32 grain." *Br.* (See p. 1168.)

This tablet is used as an expectorant. Its effects are the same as would be those of its ingredients if administered in solution. Each lozenge contains one-thirtieth of a grain (0.002 Gm.) of morphine salt, and one-tenth of a grain (0.006 Gm.) of ipecacuanha.

TROCHISCI POTASSII CHLORATIS. U. S. (Br.)

TROCHES OF POTASSIUM CHLORATE Troch Pot. Chlorat.

(trō-ḳĭs'cī pō-tăs'sĭ-ī ḳhlō-rā'tĭs)

Trochiscus Potassii Chloratis, *Br.;* Potassium Chlorate Lozenge, Chlorate of Potash Lozenges; Tablettes de Chlorate de Potasse, *Fr. Cod.;* Kaliumchloratpastillen, Pastillen von Chlorsaurem Kali, *G.;* Pastiglie di clorato di potassio, *It.;* Tabletas de clorato potasico, *Sp.*

* "Potassium Chlorate, in fine powder, *fifteen grammes* [or 231 grains]; Sugar, in fine powder, *sixty grammes* [or 2 ounces av., 51 grains]; Tragacanth, in fine powder, *three grammes* [or 46 grains]; Water, *a sufficient quantity,* to make *one hundred troches.* Mix the sugar with the tragacanth by trituration in a mortar; then transfer the mixture to a sheet of paper, and by means of a bone or wooden spatula mix it with the potassium chlorate, being careful to avoid unnecessary trituration or pressure, which might cause the mixture to ignite or explode. Lastly form a mass with water and divide it into *one hundred troches.*" *U. S.*

"Potassium Chlorate, 0.2 *gramme.* Mix with the *Rose Basis* to form a Lozenge." *Br.* (See p. 1168.)

These lozenges are employed as mildly stimulant and astringent in cases of *sore throat,* although in commercial usage the official troches are almost entirely replaced by compressed tablets of potassium chlorate.

TROCHISCUS SANTONINI. Br.

SANTONIN LOZENGE

(trō-ḳĭs'cŭs săn-tō-nĭ'nī)

Trochisci Santonini, *U. S. VIII;* Troches of Santonin; Tablettes de Santonine, *Fr. Cod.;* Pastilli Santonini, *P. G.;* Santoninpastillen, *G.;* Pastiglie de santonina, *It.;* Tabletas de santonina, *Sp.*

"Santonin, 0.06 *gramme.* Mix with the *Simple Basis* to form a Lozenge." *Br.* (See p. 1168.)

Troches of santonin were deleted from the U. S. P. IX, but are official in the N. F. IV (see Part III).

The U. S. P. VIII process was faulty in the direction that the santonin should be in fine powder, an error which has been continued in the N. F. The longer the absorption of santonin is delayed in the intestines the more prolonged and consequently the more effective is its vermicidal influence. As soon as it is absorbed it ceases to act upon the worm, and becomes a more or less deleterious substance in the system. A dose of santonin in crystals which is not poisonous may become somewhat toxic when given in fine powder. The proportion of crystals in the lozenge mass (2½ per cent.) is not sufficient to prevent the formation of a good lozenge from a pharmaceutical point of view. The National Formulary lozenge contains about half a grain (0.032 Gm.) of santonin. The Br. formula calls for about one grain (0.065 Gm.).

Dose, for an adult, of the Br. lozenge, from one to three lozenges; of the N. F., two to six.

TROCHISCI SODII BICARBONATIS. U. S.

TROCHES OF SODIUM BICARBONATE Troch. Sod. Bicarb.

(trō-ḳĭs'cī sō'dĭ-ī bī-căr-bō-nā'tĭs)

Trochiscus Sodii Bicarbonatis, *Br.;* Sodium Bicarbonate Lozenge; Trochisci Natri Bicarbonici; Tablettes de Bicarbonate de Soude, *Fr. Cod.;* Pastilles de Vichy, Pastiles digestives, *Fr.;* Natronpastillen, Natriumbicarbonatpastillen, *G.;* Pastiglie di bicarbonato di sodio, *It.;* Tabletas de bicarbonato sodico, *Sp.*

* "Sodium Bicarbonate, *eighteen grammes* [or 278 grains]; Sugar, in fine powder, *fifty-four grammes* [or 1 ounce av., 396 grains]; Myristica, freshly grated, *one gramme* [or 15 grains]; Mucilage of Tragacanth, *a sufficient quantity,* to make *one hundred troches.* Triturate the myristica with the sugar, gradually added, until they are reduced to a fine powder, and mix this intimately with the sodium bicarbonate; then form a mass with the mucilage of tragacanth and divide it into *one hundred troches.*" *U. S.*

The U. S. troche contains about three grains (0.2 Gm.) of the alkaline salt. They may be employed to correct acid conditions of the mouth, or of the stomach. From one to six may be given for a *dose.*

TROCHISCUS SULPHURIS. Br.

SULPHUR LOZENGE

(trō-ghĭs'cŭs sŭl'phū-rĭs)

Tablettes de Soufre, *Fr. Cod.*; Schwefelpastillen, *G.*

"Precipitated Sulphur, 150 *grammes;* Acid Potassium Tartrate, in powder, 30 *grammes;* Refined Sugar, in powder, 275 *grammes;* Gum Acacia, in powder, 30 *grammes;* Tincture of Orange, 30 *millilitres;* Mucilage of Gum Acacia, 30 *millilitres.* Mix the Tincture of Orange with the powders; add the Mucilage of Gum Acacia to form a suitable mass. Divide into five hundred Lozenges. Dry them in a hot-air chamber at a moderate temperature. Each Lozenge contains 0.3 gramme of Precipitated Sulphur, or approximately 5 grains." *Br.*

These lozenges were first introduced into the "Additions" to the British Pharmacopœia 1885.

Dose, from one to six lozenges. (See *Sulphur Sublimatum,* p. 1087.)

TURPETHUM. Br.

TURPETH

(tür-pĕ'thŭm)

"Turpeth is the dried root and stem of Ipomœa Turpethum, *R.Br.*" *Br.*

Turpeth Root, Indian Jalap, Trivrit, Nisoth.

Ipomœa Turpethum (*operculina* Turpethum (L.) Peter) (Fam. *Convolvulaceæ*) is a convolvulaceous plant which is found throughout India, China, Ceylon, Australia, and is occasionally cultivated in botanical gardens as an ornamental plant. There are two varieties, viz., *Sveta* or white turpeth, and *Kirshna* or black turpeth, the former being preferred as a mild cathartic. The black variety is said to be a powerful drastic. (Watt, "*Dictionary of the Economic Products of India.*")

According to Mérat and De Lens, the root itself formerly came into commerce, but at present turpeth consists of the root and stem of the plant cut into short lengths, usually from 1.5 to 5 cm. in diameter; the central woody portion is often removed by splitting the bark on one side. The pieces are cylindrical, somewhat twisted and externally of a dull gray color. A transverse section shows a porous central wood surrounded by a broad cortical portion, containing yellowish-brown resin cells, lactiferous vessels and crystals of calcium oxalate. The fracture is short in the cortex and fibrous in the central portion. The drug has a faint odor and a nauseous taste, which is perceptible only after it has been some time in the mouth.

"In cylindrical pieces of varying length, from one to five centimetres wide, often split on one side and deprived of the central portion; longitudinally furrowed; dull grey or brown. Fracture of the bark short, of the wood fibrous; internally usually pale grey. In transverse section, a porous wood surrounded by a thick bark in which abnormal wood-bundles are frequently present. Slight odor; taste nauseous, slowly developed." *Br.*

Boutron-Chalard found in turpeth root, resin, a fatty substance, volatile oil, albumen, starch, a yellow coloring matter, lignin, salts, and ferric oxide. (*J. P. C.*, viii, 121.) The root contains 10 per cent. of resin. (Andouard, *Ann. Thér.*, 1866, 118.) According to Spirgatis this resin is a glucoside, *turpethin,* $C_{76}H_{128}O_{36}$ like that of other Convolvulaceæ, insoluble in ether, but soluble in alcohol, to which it imparts a brown color not removable by animal charcoal. To obtain it pure, the alcoholic solution is concentrated; the resin precipitated by, and afterwards boiled with, water, then dried, reduced to powder, digested with ether, and finally redissolved by absolute alcohol and thrown down by ether. After being treated several times in this way, it is obtained in the state of a brownish resin, yielding on pulverization a gray powder, which strongly irritates the mucous membrane of the nostrils and mouth, and is fusible at 182.2° C. (360° F.). It is inflammable, burning with a smoky flame and emitting irritant vapors. With strong bases it acts like jalapin, takes up water, and is transformed into a soluble acid, *turpethic acid,* $C_{34}H_{60}O_{18}$, while with dilute acids it is decomposed into *turpetholic acid,* $C_{16}H_{32}O_4$, and glucose. (*J. P. C.*, 4e sér., i, 236.)

Turpeth root is purgative, somewhat less powerful than jalap, and rather slow in its action.

Dose, five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Tinctura Jalapæ Composita, *Br.*

ULMUS. U. S.

ELM [Elm Bark Slippery Elm]

(ŭl'mŭs)

"The bark of *Ulmus fulva* Michaux (Fam. *Ulmaceæ*), deprived of the outer corky layer and dried." *U. S.*

Red Elm, Moose-elm, and Indian Elm; Cortex Ulmi Interior, Ulmi Cortex; Orme Fauve, *Fr. Cod.*; Ecorce d'Orme, *Fr.*; Ulmenrinde, Rüsterrinde, *G.*

The *slippery elm* (*Ulmus fulva*), is a lofty tree, fifty or sixty feet in height, with a trunk fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are petiolate, oblong-ovate, acuminate, nearly equal at the base, unequally serrate, pubescent, and very rough on both sides. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which are apetalous, appear before the leaves, are sessile, and in clusters at the extremities of the young shoots. The clusters of flowers are surrounded by scales, which are downy like the buds. The calyx is also downy. The stamens are five, short, and of a pale rose color. The fruit is a membranaceous capsule or samara, enclosing in

the middle one round seed, destitute of fringe.

Ulmus fulva is indigenous, growing in all parts of the United States north of the Carolinas, but most abundantly west of the Alleghany Mountains. It extends westward to the Dakotas and northward to western Quebec and Lake Huron. It flourishes in open, elevated situations, and requires a firm, dry soil. From the *white elm* (*U. americana* L.) it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark, separated from the cortex, is the part used. Large quantities are collected in the Lower Peninsula of Michigan.

Fremontia californica Torr., or *California Slippery Elm,* is not botanically allied to *Ulmus fulva;* its bark is said, however, to have the same properties as slippery elm bark, and to be used for a similar purpose.

Properties.—Elm bark is officially described as follows:

"Usually in bundles consisting of flat, oblong pieces, about 30 cm. in length and from 10 to 15 cm. in width; outer surface of a light brown or buff color with occasional dark brown patches of adhering cork, longitudinally striate and with detachable bundles of bast-fibers, and colored blackish upon the addition of a very diluted iodine T.S.; inner surface light yellowish-brown, nearly smooth and finely striate, only slightly darkened upon the addition of a very diluted iodine T.S.; fracture fibrous with projecting bast-fibers, the broken surface porous, due to the large mucilage cells; odor distinct; taste mucilaginous. The powder is very light brown; under the microscope it shows mostly fibrous fragments, and a finely granular portion made up of small starch grains, the latter being immediately colored bluish-black upon the addition of iodine T.S.; starch grains mostly spherical or more or less polygonal, usually about 0.003 mm. in diameter, but also attaining a diameter of 0.025 mm.; bast-fibers very long, about 0.02 mm. in diameter, with rather thin, slightly lignified walls; calcium oxalate in monoclinic prisms, mostly in crystal fibers, the individual crystals from 0.01 to 0.025 mm. in diameter; fragments of large mucilage cells with adhering starch grains. Macerate 1 Gm. of powdered Elm with 40 mils of distilled water for an hour and forcibly strain; the solution is of a mucilaginous consistence." *U. S.*

Ulmus abounds in mucilaginous matter, which it readily imparts to water. The mucilage is precipitated by solutions of lead acetate and subacetate, but not by alcohol. It contains a variety of tannin which colors iron solutions green, in amount about 6.5 per cent. according to Rink, or, according to Davy, a little less than 3 per cent.

Much of the bark brought into the market is of inferior quality, imparting comparatively little mucilage to water. It has the characteristic odor of the genuine bark, but is much less fibrous and more brittle, breaking abruptly when bent, instead of being capable, like the better kinds, of being folded lengthwise without breaking. To what this inferiority is owing, whether to difference in the species or the age, or to circumstances in the growth of the tree producing it, we are unable to state. Ground elm bark is said to be adulterated, usually with substances containing starch. Roberts found commercial specimens which possessed considerable of a brownish outer bark still adhering to them. One specimen was partly mouldy and had considerable adhering wood. (*Proc. Penn. Ph. Assoc.,* 1913, p. 85.) The following test, devised by Geo. M. Beringer, seems to have practical value: Ten grains of ground or pulverized elm bark, thoroughly shaken with one fluidounce of water, will, if pure and of good quality, in fifteen minutes form a thick jelly-like mass of a fawn color.

C. W. Wright, of Cincinnati, in a communication to the *Western Lancet,* states that slippery elm bark has the property of preserving fatty substances from rancidity, and that this fact was known to the Indians, who prepared bear's fat by melting it with the bark, in the proportion of a drachm of the latter to a pound of the former, keeping them heated together for a few minutes, and then straining off the fat. Wright tried the same process with butter and lard, and found them to remain perfectly sweet for a long time. (*A. J. P.,* xxiv.)

Uses.—Elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in *dysentery, diarrhea,* and *diseases of the urinary passages.* Its mucilage is reputed to be nutritious.

It is commonly used as a drink in the form of infusion. (See *Mucilago Ulmi.*) The powder may be used stirred in hot water, with which it forms a mucilage more or less thick according to the proportion added. The bark also serves as an emollient application in cases of *external inflammation.* For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. McDowell, of Virginia, recommended slippery elm bark for the dilatation of *fistulas* and *strictures* (*Med. Examiner,* i, 244); subsequently H. R. Storer, of Boston, used it advantageously for *dilating the os uteri* (*B. M. S. J.,* liii, 300), and A. Abbe of the same place, succeeded in curing with it a case of *stricture of the rectum* (*B. M. S. J.,* liv, 349).

Off. Prep.—Trochisci Ulmi, *N. F.*

UNGUENTA.

OINTMENTS

(ụn-guĕn'tạ)

Pommades, Onguents, *Fr.;* Salben, *G.:* Pomatas, Unguentos, *It.;* Pomadas, Unguentos, *Sp.*

These are fatty substances, softer than cerates, of a consistence like that of butter, and such that they may be readily applied to the skin by inunction. When ointments are prepared

by merely mixing medicinal substances with simple ointment, hydrous wool-fat, lard, or petrolatum, care should be taken, if the added substance be a powder, that it be brought to the finest possible state of division before being incorporated with the unctuous matter. If soluble in water or in alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with water or alcohol, according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to rancidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, or with poplar buds, as recommended by Deschamps (*A. J. P.*, xv, 260); but care should be taken that there be no therapeutic objection to the admixture. Elm bark is said to have the same effect. (See p. 1172.) According to Geisler, ten drops of spirit of nitrous ether, incorporated with an ounce of ointment, will overcome the disagreeable fatty odor. (*Ph. Cb.*, 1847, 927.) Hydrous wool-fat or lanolin, petrolatum, and glycerite of starch are now used as vehicles for ointments. (See *Adeps Lanæ Hydrosus, Petrolatum,* and *Glyceritum Amyli.*) In the selection of a vehicle for an ointment it is important to consider the object for which the ointment is to be used. Lanolin is a natural emollient of the skin, composed of cholesterin and other substances.

Glycelæum is an oleaginous compound of finely powdered almond meal 1 part, glycerin 2 parts, and olive oil 6 parts. It was proposed by T. B. Groves, *C. D.*, Sept. 14, 1867, as a substitute for plasma and other fatty bodies, and has no doubt advantages, one of which is the facility with which it can be removed from the skin by a wet sponge. It has been proposed to substitute glycerin for oils and fats in the preparation of ointments, either wholly or in part; but ointments thus prepared are altogether unfit for application by inunction, as a portion of the glycerin remains upon the skin, producing a rough sensation of adhesiveness, very different from the softness caused by oleaginous matter, and in some skin diseases glycerin in an ointment would be positively injurious.

The cerates having been abolished as a class in the British Pharmacopœia, a few of the individual articles have been transferred to the ointments, making the definition of the latter class of preparations, as given above, not exactly applicable to all the individual substances at present included among them in that Pharmacopœia. We consider no substance to be strictly entitled to the name of ointment which is not of such a consistence as to adapt it to application to the skin by friction or inunction. Ointments should be dispensed in glass, porcelain, or queensware pots or jars, or, if for temporary use, in tight wooden boxes. We have used a very convenient method of dispensing soft ointments by introducing them into compressible tubes. These tubes are similar to those used for holding artists' colors, and have the advantage of shielding the ointment from the oxidizing action of the air while allowing the use of the desired quantity. Vanderkleed and Heidlberg (*Proc. P. P. A.*, 1913, p. 312) state that the only satisfactory method of determining whether or not the proper degree of subdivision has been attained is by the use of the microscope, and call attention to some of the precautionary measures which should be taken in order to obtain correct results. Their article is illustrated by numerous photographic representations of ointments of different degrees of fineness. For a classification of ointments in accordance with their therapeutic use, by C. S. N. Hallberg, see *West. Drug.*, 1900, 652.

Uses.—Ointments are used either for their local effects upon the skin or as a means of introducing drugs into the system through endermic absorption. The effects of fat-like substances upon the skin are due in part to their softening or emollient properties, and in part to the protection of the epiderm from the air, bacteria, or friction; they may also serve as carriers of antiseptic or other medicaments which influence pathological conditions of the skin. It is manifest that different qualities for an ointment base are desirable according to the purpose for which it is intended. Thus if it is intended to protect the skin the choice should fall on a substance which is not irritant nor readily absorbed nor liable to become liquid at a body temperature. On the other hand, for endermic administration one should choose a base which easily penetrates the skin. Concerning this last factor there has been a considerable amount of experimental investigation with not altogether harmonious results. The most widely used method has been to rub into the skin ointments made with various bases containing some substance easily demonstrable in the urine, and then determining the proportion of the medicament eliminated. Hirschfeld and Pollio (*Arch. f. Derm. u. Syph.*, 1904, lxxii, p. 163) found that the iodides were absorbed readily in ointments made with petrolatum or lard, but almost not at all from ointments made from wool fat. Bourjet (*Th. M.*, 1893) found that salicylic acid was absorbed readily from ointments made with true fats but poorly in those made with petrolatum or glycerin as the base. Sauerland (*Biochem. Zeit.*, 1912, xl, p. 56) in an elaborate research found that with vaseline, 40 per cent., with lard, 26 per cent., and with wool-fat, 18 per cent. of the iodine of iothion was absorbed through the skin; likewise methyl salicylate was absorbed in the same order, although in much smaller proportions. On the other hand, spirosal, a glycol salicylate, was absorbed scarcely at all from a lard ointment, but in fair amounts from either wool-fat or vaseline. Gardiner (*B. M. J.*, 1912, i, p. 238) rubbed ointments containing various stains into the shaven skin of guinea pigs and then examined the skin microscopically to ob-

serve the depth of penetration. He found that olive oil penetrated more deeply than any substance with which he experimented, but that goose grease and lard also penetrated well. Petrolatum remained limited to the very superficial portions of the skin. Wool-fat, while it penetrated somewhat more deeply than petrolatum, was noticeably behind lard. Wild (*B. M. J.*, 1911, ii, p. 161) employed a very different method to study this subject. He rubbed pure ointment bases into the skin for a measured time and then scraped off what was left on the skin and weighed. The difference between the quantity taken and that recovered he considered to represent the amount absorbed. He found that petrolatum was absorbed practically not at all, that of lard or olive oil about 15 per cent., and of hydrous wool-fat about 20 per cent., but that the absorption of the latter was noticeably less if it was deficient in water. While the evidence quoted is somewhat contradictory and it is probable that some ointment bases are better for one drug and some for another, yet it seems to us that in a general way the conclusion is justified that where absorption is desired lard is probably the best of the official ointment bases.

UNGUENTUM. U. S.

OINTMENT Ung. [Simple Ointment]

(ŭn-guĕn′tŭm)

Unguentum Adipis, *U. S.* 1860; Unguentum Simplex; Pommade simple, *Fr.*; Unguentum cereum, *P. G.*; Wachssalbe, *G.*

* "White Wax, *two hundred grammes* [or 7 ounces av., 24 grains]; Benzoinated Lard, *eight hundred grammes* [or 28 ounces av., 96 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the white wax, add the benzoinated lard, and heat gently until liquefied; then stir the mixture until it congeals. For use in southern latitudes and during the warm season in other localities, 50 Gm. of the benzoinated lard (or more if necessary) may be replaced by an equal quantity of white wax." *U. S.*

Yellow wax was used in this ointment in the U. S. P., 1890, and objection was made to the color of the ointment. It has been very properly replaced by white wax in the U. S. P. VIII and IX, and the lard is now benzoinated.

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle, it being the basis of several official ointments.

UNGUENTUM ACIDI BORICI. U. S., Br.

OINTMENT OF BORIC ACID Ung. Acid. Bor.

(ŭn-guĕn′tŭm ăç′ĭ-dī bō′rĭ-cī)

Pommade de l'Acide Borique, *Fr.*; Unguentum Acidi Borici, *P. G.*; Borsalbe, *G.*

* "Boric Acid, in fine powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Paraffin, *fifty grammes* [or 1 ounce av., 334 grains]; White Petrolatum, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the paraffin, add the white petrolatum, and heat gently until liquefied. Then gradually add the hot liquid to the boric acid, contained in a warm mortar, triturating thoroughly, and stir the mixture until it congeals." *U. S.*

"Boric Acid, in powder, 10 *grammes;* Paraffin Ointment, white, 90 *grammes.* Melt the Paraffin Ointment; sift in the Boric Acid; stir until cold." *Br.*

Theodore Faber (*Ph. Ztg.*, 1914, p. 163) finds that boric acid in ointments may be readily and accurately estimated by the method of Jörgensen, in which it is converted into glycerin boric acid and estimated by titration with normal potassium hydroxide volumetric solution, as in the official method for estimating boric acid, the operation being carried out at a temperature sufficiently high to melt the fat, the presence of which may be disregarded.

This ointment was introduced into the U. S. P. (8th Rev.); it closely resembles the British ointment.

Uses.—This ointment probably has no superiority over plain white petrolatum. The prevalent belief that it has antiseptic properties because of the boric acid in it has no scientific support.

UNGUENTUM ACIDI SALICYLICI. Br.

SALICYLIC ACID OINTMENT

(ŭn-guĕn′tŭm ăç′ĭ-dī săl-ĭ-cŷl′ĭ-cī)

Pommade d'Acide Salicylique, *Fr.*; Salicylsalbe, *G.*

"Salicylic Acid, in powder, 2 *grammes;* Paraffin Ointment, white, 98 *grammes.* Melt the Paraffin Ointment; sift in the Salicylic Acid; stir until cold." *Br.*

UNGUENTUM ACIDI TANNICI. U. S.

OINTMENT OF TANNIC ACID Ung. Acid. Tann.

(ŭn-guĕn′tŭm ăç′ĭ-dī tăn′nĭ-cī)

Pommade d'Acide tannique, Pommade de Tannin, *Fr.*; Tanninsalbe, *G.*

* "Tannic Acid, *twenty grammes* [or 308.6 grains]; Glycerin, *twenty grammes* [or 308.6 grains]; Ointment, *sixty grammes* [or 2 ounces av., 51 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the tannic acid in the glycerin with the aid of a gentle heat, and mix the solution thoroughly with the ointment, avoiding the use of iron utensils." *U. S.*

Ointment of Tannic Acid was doubled in strength at the U. S. P., 1890, revision. It is an excellent application in many cases of *piles* and *prolapsus ani*, also for *flabby ulcers.*

UNGUENTUM ACONITINÆ. Br.

ACONITINE OINTMENT

(ŭn-guĕn′tŭm ăc-ŏn-ĭ-tī′næ)

Pommade d'Oléate d'Aconitine, Pommade d'Aconitine, *Fr.*; Akonitinoleatsalbe, Akonitinsalbe, *G.*

"Aconitine, 2 *grammes;* Oleic Acid, 16 *grammes;* Prepared Lard, 82 *grammes.* Tritu-

rate the Aconitine with the Oleic Acid, and gently warm the mixture until dissolved; add the Prepared Lard; mix. This Ointment contains 2 per cent. of Aconitine. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

For the uses of this preparation the reader is referred to the articles on *Aconitum* and *Aconitina.* Care must be taken not to apply it too freely nor to an abraded or ulcerated surface, lest it produce serious constitutional effects.

UNGUENTUM AQUÆ ROSÆ. U. S., Br.

OINTMENT OF ROSE WATER Ung. Aq. Ros.

(ụn-guĕn'tŭm ă'quæ rō'şæ)

Rose Water Ointment; Unguentum Emolliens; Cold-cream, Ceratum Galeni, Galen's Cerate, *Fr. Cod.*: Cérat cosmétique, Crême froide, *Fr.*; Unguentum leniens, *P. G.*; Cold Cream, *G.*

* "Spermaceti, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; White Wax, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Expressed Oil of Almond, *five hundred and sixty grammes* [or 19 ounces av., 330 grains]; Sodium Borate, in fine powder, *five grammes* [or 77 grains]; Stronger Rose Water, *one hundred and ninety grammes* [or 6 ounces av., 307 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Reduce the spermaceti and the white wax to fine pieces and melt them on a water bath, add the expressed oil of almond and stir, continuing the heat until the mixture is uniform. Dissolve the sodium borate in the stronger rose water warmed on a water bath to the temperature of the melted wax and fat, and add the warm solution gradually to the melted mixture, stirring it rapidly and continuously until it congeals and becomes of uniform consistence. Ointment of Rose Water must be free from rancidity. If the Ointment has been chilled, warm it slightly before attempting to incorporate other ingredients with it." *U. S.*

"Rose Water, 20.0 *millilitres;* White Beeswax, 18.0 *grammes;* Purified Borax, 1.0 *gramme;* Almond Oil, 61.0 *grammes;* Oil of Rose, 0.1 *millilitre.* Melt the White Beeswax in the Almond Oil; add, with constant stirring, the Borax previously dissolved in the Rose Water; add the Oil of Rose, and continue to stir until cold." *Br.*

In the U. S. P., 1890, process the proportion of stronger rose water was greatly reduced—*i.e.*, from 30 to 20 per cent.; this makes a more stable preparation, but in our opinion the usefulness of the ointment has been curtailed by the reduction, its soft consistence being one of its most valuable characteristics. Sodium borate was added to increase its whiteness; its presence may, however, prove objectionable when the ointment is used as a basis in prescriptions, by reacting with some of the ingredients ordered by the physician. The U. S. P. VIII formula was retained with but slight changes in the U. S. P. IX. The manipulation was somewhat modified to increase uniformity of the product.

This preparation is a white, very soft, and elegant ointment, deriving a grateful odor from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. We have found it an improvement to add oil of rose in the proportion of one drop to eight ounces, and, when made in the official quantity, to use an instrument known as the "Dover egg-beater" for giving it the desired creamy appearance. In larger amounts an ice cream churn is well adapted for this purpose. It is a pleasant, cooling application to irritated and excoriated surfaces, and may be used with great advantage for *chapped lips* and *hands*, so frequent in cold weather. It is a preparation of very early origin and is sometimes known by the name of Galen's Cerate. "Cold" cream is not recognized in the U. S. Pharmacopœia IX as an official synonym for ointment of rose water. This course became necessary because of the large number of unofficial ointments of varying composition popularly exploited as cold creams, and these were frequently dispensed, when physicians' prescriptions directed Ointment of Rose Water. The commercial cold creams must be made from substances which are not liable to rancidity, and paraffin oil, liquid petrolatum, white petrolatum, etc., largely form the basis of such, but the official ointment is to be preferred for use in prescriptions. W. C. Alpers furnishes the following formula for a cold cream which is more permanent than the official ointment. One hundred and fifty parts of white wax is melted in 600 parts of paraffin oil with the aid of a gentle heat; 9 parts of borax is dissolved in 240 parts of water; the two fluids are brought to a uniform temperature, not exceeding 60° C. (140° F.), and the aqueous solution is poured into the oily one in a continuous stream, stirring gently for a minute or two; then 1 part of oil of geranium and a little oil of rose are added while stirring, and the product while still warm is poured into jars. The cold cream so obtained is white, soft and smooth, pleasantly odorous, keeps well in the heat of summer and the cold of winter, and becomes only slightly thinner in summer. As the ointment is liable to become rancid when long kept, and the water to separate upon exposure, Joseph Laidley has proposed the substitution for the rose water of oil of rose and glycerin, the former in the proportion of two drops, the latter in that of four fluidrachms, the quantity of spermaceti being increased by two drachms. (*A. J. P.*, xii, 119.) For some purposes the substitution is useful, but the official preparation is preferable for *chapped hands*, as the glycerin frequently leaves an unpleasant sensation of stickiness on the skin.

UNGUENTUM ATROPINÆ. Br.

ATROPINE OINTMENT

(ụn-guĕn'tŭm ăt-rọ-pĭ'næ)

Pommade d'Oléate d'Atropine, Pommade d'Atropine, *Fr.*; Atropinoleatsalbe, Atropinsalbe, *G.*

"Atropine, 2 *grammes;* Oleic Acid, 8 *grammes;* Prepared Lard, 90 *grammes.* Triturate the

Atropine with the Oleic Acid, and gently warm the mixture until dissolved; add the Prepared Lard; mix. This Ointment contains 2 per cent. of Atropine. In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

For the uses of this ointment, see *Belladonna* and *Atropina*, p. 222 and p. 207. Caution must be observed that the ointment shall not come in contact with abraded, ulcerated, or wounded surfaces, and that it be not applied too freely to sound skin.

UNGUENTUM BELLADONNÆ. U. S., Br.

BELLADONNA OINTMENT Ung. Bellad.

(ụn-guĕn'tŭm bĕl-lą-dŏn'næ)

Pommade Belladonée, *Fr. Cod.*; Pommade de Belladone, *Fr.*; Belladonnasalbe, Tollkirschensalbe, *G.*

* "Pilular Extract of Belladonna Leaves, *ten grammes* [or 154 grains]; Diluted Alcohol, *five mils* [or 81 minims]; Hydrous Wool-fat, *thirty grammes* [or 1 ounce av., 25.5 grains]; Benzoinated Lard, *fifty-five grammes* [or 1 ounce av., 411 minims], to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the extract with the diluted alcohol until a smooth mixture is obtained; with this incorporate the hydrous wool-fat; then add the benzoinated lard and mix thoroughly." *U. S.*

"Liquid Extract of Belladonna, 80 *millilitres;* Benzoated Lard, 60 *grammes;* Wool Fat, 20 *grammes.* Evaporate the Liquid Extract of Belladonna on a water-bath until it is reduced to twenty grammes; mix with the Benzoated Lard and Wool Fat. This Ointment contains 0.6 per cent. of the alkaloids of Belladonna Root. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoinated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This is a convenient form for the external application of extract of belladonna. Care must be taken in preparing it that the extract employed have the due consistence, and, if dry and lumpy, it may be restored to the proper state by rubbing it with a little water in a heated mortar. The use of diluted alcohol, as now officially directed, is still better.

UNGUENTUM CANTHARIDINI. Br.

CANTHARIDIN OINTMENT

(ụn-guĕn'tŭm cạn-thăr-ị-dĭ'nī)

Unguentum Irritans, Unguentum ad Fonticulos; Pommade Epispastique (jaune, verte), *Fr. Cod.*; Onguent de Cantharides, *Fr.*; Unguentum Cantharidum, *P. G.*; Spanischfliegensalbe, *G.*; Unguento de cantaridas, *Sp.*

"Cantharidin, 0.1 *gramme;* Chloroform, 10.0 *millilitres;* Benzoated Lard, 290.0 *grammes.* Dissolve the Cantharidin in the Chloroform; add the solution to the Benzoated Lard, previously melted; stir until cold. This Ointment contains 0.033 per cent. of Cantharidin, which is approximately two-thirds of the proportion of Cantharidin contained in the Unguentum Cantharidis of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

Cantharidin ointment of the Br. Pharm., 1914, is made by dissolving cantharidin, the blistering principle of Spanish flies, in chloroform and incorporating the solution in benzoated lard. This should make an effective ointment.

It should be recollected that this ointment is intended as a dressing for blisters, not to produce vesication. The U. S. Committee of Revision wisely deleted this preparation many years ago, as it was frequently prescribed under the impression that it was equal in strength to the cerate, in fact, identical with it, and disappointment resulted. Such a preparation should be left to extemporaneous prescription. *Dupuytren's ointment,* employed as a local application to *prevent the loss of hair,* was made by macerating a drachm of Spanish flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard.

UNGUENTUM CAPSICI. Br.

CAPSICUM OINTMENT

(ụn-guĕn'tŭm căp'sị-cī)

Pommade de Piment des Jardins, *Fr.*; Spanisch-Pfeffersalbe, *G.*

"Capsicum Fruit, bruised, 25 *grammes;* Hard Paraffin, 10 *grammes;* Soft Paraffin, 75 *grammes;* Prepared Lard, 10 *grammes.* Digest on a water-bath for one hour, stirring occasionally; strain; stir until cold. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

This is an active counter-irritant which may be used in the place of liquid liniments in *sprains, bruises, rheumatism,* and other inflammations.

UNGUENTUM CETACEI. Br.

SPERMACETI OINTMENT

(ụn-guĕn'tŭm cẹ-tā'cẹ-ī)

Pommade de baleine, *Fr.*; Walrathsalbe, *G.*

"Spermaceti, 20 *grammes;* White Beeswax, 8 *grammes;* Liquid Paraffin, 72 *grammes.* Melt together, and stir until cold." *Br.*

This ointment is employed as a mild dressing for *blisters, wounds,* and *excoriated surfaces,* or as the basis for carrying more active ingredients. It should be made in small quantities at a time, as it is apt to become rancid when long kept.

UNGUENTUM CHAULMOOGRÆ. Br.

CHAULMOOGRA OINTMENT [Gynocardia Ointment]

(ụn-guĕn'tŭm châul-mōōg'ræ)

"Chaulmoogra Oil, 10 *grammes;* Hard Paraffin, 40 *grammes;* Soft Paraffin, white, 50 *grammes.* Melt the Hard and Soft Paraffins to-

gether; add the Chaulmoogra Oil; stir until cold." *Br.*

This is intended for its local effects; it is not suitable for obtaining the systemic actions of chaulmoogra oil. (See *Oleum Chaulmoogra.*)

UNGUENTUM CHRYSAROBINI. U. S., Br.

CHRYSAROBIN OINTMENT Ung. Chrysarobin.

(ụn-guĕn'tŭm ȼhrȳs-ą-rọ-bī'nī)

Pommade de Chrysarobine, Pommade de Poudre de Goa, *Fr.*; Chrysarobinsalbe, Goapulversalbe, *G.*

* "Chrysarobin, *six grammes* [or 92.5 grains]; Benzoinated Lard, *ninety-four grammes* [or 3 ounces av., 138 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the chrysarobin with the benzoinated lard previously melted, and heat the mixture on a water bath for twenty minutes with occasional stirring; then strain and stir until it congeals." *U. S.*

"Chrysarobin, in powder, 4 *grammes;* Soft Paraffin, 96 *grammes.* Triturate the Chrysarobin with a portion of the Soft Paraffin until smooth; gradually add the remainder, mixing thoroughly by trituration." *Br.*

This ointment was reduced one-half in strength at the U. S. P., 1890, revision, but was slightly increased in strength in the U. S. P. IX; it is now about one-third stronger than the British ointment. It is a valuable agent in *psoriasis, ringworm,* and other *diseases of the skin,* but has the great drawback of leaving a permanent stain upon the linen. It is preferably made by dissolving the chrysarobin in a little hot benzene, mixing this rapidly with a portion of the melted lard, and subsequently stirring before adding the rest of the lard.

UNGUENTUM COCAINÆ. Br.

COCAINE OINTMENT

(ụn-guĕn'tŭm cō-cą-ī'næ)

Pommade d'Oléate de Cocaine, *Fr.*; Cocainoleatsalbe, *G.*

"Cocaine, 4 *grammes;* Oleic Acid, 16 *grammes;* Prepared Lard, 80 *grammes.* Triturate the Cocaine with the Oleic Acid, and gently warm the mixture until the alkaloid is dissolved; add the Prepared Lard; mix. This Ointment contains 4 per cent. of Cocaine. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

UNGUENTUM CREOSOTI. Br.

CREOSOTE OINTMENT

(ụn-guĕn'tŭm crē-ọ-sō'tī)

Pommade Créosotée, Pommade de Créosote, *Fr.*; Kreosotsalbe, *G.*

"Creosote, 10 *grammes;* Hard Paraffin, 40 *grammes;* Soft Paraffin, white, 50 *grammes.* Melt the Hard and Soft Paraffins together; add the Creosote; stir until cold." *Br.*

The British ointment is more than twice as strong as that official in the U. S. P., 1870, which was made by mixing half a fluidrachm of creosote with a troyounce of lard. For the use of this ointment, see *Creosotum.* It may sometimes be advantageously diluted with lard when found to irritate.

UNGUENTUM DIACHYLON. U. S.

DIACHYLON OINTMENT Ung. Diachyl.

(ụn-guĕn'tŭm dī-ăȼh'y-lŏn)

Unguentum Plumbi Hebræ; Hebra's Lead Ointment; Ongueat Diachylon, Pomade de Diachylon, *Fr.*; Unguentum diachylon, *P. G.*; Bleipflastersalbe, Diachylonsalbe, *G.*

* "Lead Plaster, *fifty grammes* [or 1 ounce av., 334 grains]; Oil of Lavender, *one gramme* [or 15 grains]; White Petrolatum, *forty-nine grammes* [or 1 ounce av., 319 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Melt together the lead plaster and the white petrolatum by applying a gentle heat, strain the mixture, allow it to cool but not congeal, add the oil of lavender, and stir the Ointment until it is cold." *U. S.*

This ointment has been largely used by dermatologists in *eczema* and other *skin diseases.* It is frequently called "*Unguentum Diachylon Hebræ,*" on account of its extensive use by Hebra, of Vienna. Vulpius states that the ointment used at Hebra's clinic, made according to the following formula, is very superior and will keep for weeks: Twenty parts of litharge are heated with sufficient water and eighty parts of olive oil until the reaction is completed, when one part of oil of lavender is added to the strained and cooling mass.

Our experience with the ointment made by the latter formula is that the tendency to rancidity constitutes its greatest objection, and in warm weather it is impossible to keep it longer than a few days. If even slightly rancid, it is unfit for use in most cases. A. Deringer (*Ph. Z. R.,* 1880, p. 103; *A. J. P.,* Sept., 1880) recommended the following modification: Dissolve 200 grammes of lead acetate in 1 liter of distilled water and 300 grammes of white Marseilles soap in 1½ liters of distilled warm water, filter both solutions, mix, wash the resulting precipitate frequently with distilled water, and, after removing the moisture from it as much as possible, melt 1 part of it together with 1½ parts of the best olive oil with a steam evaporating apparatus, and triturate into a white, smooth ointment in a mortar, which then possesses all the excellent mild and healing properties of Hebra's ointment. (See *Emplastrum Plumbi,* page 415.)

Eisner's modification, approved by L. A. Duhring, is as follows: One part of freshly precipitated (from lead acetate) pure white lead hydroxide is rubbed with two parts of water, and mixed well with six parts of the best Lucca olive oil. It should be stirred for about two hours over a hot water bath, and cooled with constant stirring until the proper

consistence is obtained. While cooling, a drachm of oil of lavender is to be added to each half-pound of ointment. (*M. T. G.*, May 7, 1881.)

UNGUENTUM EUCALYPTI. Br.

EUCALYPTUS OINTMENT

(ụn-guĕn'tŭm eū-cạ-lўp'tī)

Pommade d'Eucalypte, *Fr.*; Eukalyptussalbe, *G.*

"Oil of Eucalyptus, 10 *grammes;* Hard Paraffin, 40 *grammes;* Soft Paraffin, white, 50 *grammes.* Melt the Hard and Soft Paraffins together; add the Oil of Eucalyptus; stir until cold." *Br.*

This ointment is used as a stimulant to indolent *ulcers* and in *skin diseases.*

UNGUENTUM GALLÆ. U. S., Br.

NUTGALL OINTMENT Ung. Gall.

(ụn-guĕn'tŭm găl'læ)

Gall Ointment; Ointment of Galls; Pommade de Noix de Galle, *Fr.*; Galläpfelsalbe, *G.*

* "Nutgall, in very fine powder, *twenty grammes* [or 308.6 grains]; Ointment, *eighty grammes* [or 2 ounces av., 360 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the nutgall with the ointment, gradually added, until they are thoroughly mixed. Avoid the use of metallic utensils." *U. S.*

"Galls, in powder, 20 *grammes;* Benzoated Lard, 80 *grammes.* Triturate the Galls with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

Care should be taken to have the nutgall in very fine powder and thoroughly sifted. This ointment is used chiefly in *piles* and *prolapsus ani,* and in *flabby* or *indolent ulcers.*

Off Prep.—Unguentum Gallæ cum Opio, *Br.*

UNGUENTUM GALLÆ CUM OPIO. Br.

GALL AND OPIUM OINTMENT

(ụn-guĕn'tŭm găl'læ cŭm ō'pĭ-ō)

"Gall Ointment, 92.5 *grammes;* Opium, in powder, 7.5 *grammes.* Triturate the Opium with a portion of the Gall Ointment until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment contains 7.5 per cent. of Opium." *Br.*

This combination of galls and opium is sometimes employed for *hemorrhoids.* From two to four per cent. of camphor is sometimes added.

UNGUENTUM HAMAMELIDIS. Br.

HAMAMELIS OINTMENT

(ụn-guĕn'tŭm hăm-ạ-mĕl'ĭ-dĭs)

Pommade de Hamamélis, *Fr.*; Hamamelissalbe, *G.*

"Liquid Extract of Hamamelis, 10 *millilitres;* Wool Fat, 60 *grammes;* Soft Paraffin, 30 *grammes.* Mix by trituration in a warm mortar." *Br.*

This was one of the "Additions" to the British Pharmacopœia, 1885, and afterwards introduced into the Br. Pharm., 1898, 1914. It is, in our opinion, of doubtful utility, but may be applied to *sprains.*

UNGUENTUM HYDRARGYRI. U. S., Br.

MERCURIAL OINTMENT Ung. Hydrarg.

(ụn-guĕn'tŭm hў-drär'gў-rī)

Mercury Ointment; Unguentum Mercuriale, s. Neapolitanicum; Pommade mercurielle à parties égales, Onguent mercuriel double, Onguent Napolitain, *Fr. Cod.*; Pommade napolitaine, *Fr.*; Unguentum Hydrargyri Cinereum, *P. G.*; Graue Quecksilbersalbe, *G.*

* "Mercury, *five hundred grammes* [or 17 ounces av., 279 grains]; Oleate of Mercury, *twenty grammes* [or 308.6 grains]; Prepared Suet, *two hundred and thirty grammes* [or 8 ounces av., 49 grains]; Benzoinated Lard, *two hundred and fifty grammes* [or 8 ounces av., 358 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the oleate of mercury in a warm mortar with the mercury added gradually, and when the globules are completely divided and distributed, set it aside for about fifteen minutes. Melt the lard and suet, allow the mixture to partially cool, add about *twenty-five grammes* [or 386 grains] of it to the mercurial mixture, and continue the trituration until globules of mercury are no longer visible under a lens magnifying ten diameters. Then add the remainder of the lard and suet and mix thoroughly." *U. S.*

Assay.—"Weigh 10 Gm. of Mercurial Ointment in a tared dish, melt it, then remove it from the fire and add 50 mils of warm purified petroleum benzin. Stir the mixture well, allow the mercury to settle completely, and decant the benzin. Wash the residue with successive portions of 10 mils each of warm purified petroleum benzin until it is entirely free from fatty matter, carefully retaining all of the separated Mercury in the dish, and allowing all traces of the benzin to evaporate. Add to the residue 10 mils of diluted hydrochloric acid, heat it gently and stir with a glass rod until the mercury collects in a globule. Pour off the acid, warm the mercury with a little distilled water, dry the globule on bibulous paper, and weigh. The separated mercury weighs not less than 4.9 Gm. nor more than 5.1 Gm." *U. S.*

"Mercury, 30 *grammes;* Benzoated Lard, 65 *grammes;* Prepared Suet, 5 *grammes.* Triturate until metallic globules cease to be visible. This Ointment is of approximately three-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898; it is of the same strength as the Unguentum Hydrargyri of the International Agreement. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

The U. S. P. IX ointment contains 50 per cent.

of mercury which was the strength of the Br. Pharm., 1898, ointment. In the Br. Pharm., 1914, the strength was reduced to 30 per cent. (corresponding with the International Protocol); but the title was not changed. The U. S. P. VIII introduced diluted mercurial ointment, 30 per cent. (See *Unguentum Hydrargyri Dilutum.*)

The U. S. official formula is particularly adapted to the extemporaneous preparation of this ointment, it having been shown that the extinguishment of the mercury is facilitated by the use of oleate of mercury, while its presence undoubtedly adds to the efficiency of the ointment. Oleic acid was suggested by Leo Eliel (see *Indiana Pharmacist,* 1888) in the proportion of 1 per cent. for the extinction of the mercury. The addition of 4 per cent. of compound tincture of benzoin aids in the preservation of the ointment. The trituration should not be accompanied with pressure, a light, rapid motion of the pestle being most effective. In the preparation of mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is usually performed upon the large scale in a marble mortar, as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished when a portion of the mass, rubbed upon paper, exhibits no metallic globules under a magnifying glass of ten diameters. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. (For the details of many of these older processes see *U. S. D.,* 19th ed., p. 1310.)

E. R. Squibb prepared this ointment by succussion in an apparatus which agitates the mixture of fats and mercury until the metal is extinguished. When prepared with lard alone, the ointment is liable, in hot weather, to become so soft as to allow the metal to separate. Hence the official use of suet, and even a larger proportion might be employed, during the summer season. Christison states that the better plan is not to complete the process by a continuous trituration, but to operate for a short time every day and allow the ointment in the meantime to be exposed to the air. But so much time and labor are required in this process that the ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a heat of about 37.7° C. (100° F.), are triturated with the metal by means of two iron balls which are driven rapidly around in a circular trough by steam power. The extinguishment of the mercury is thus effected in about twelve hours. In buying from the manufacturer, great care should be exercised by the pharmacist, as much of the commercial ointment contains less than the official percentage of mercury. Indeed, it is sometimes found in the market without a trace of mercury, having been made by mixing up lamp black with rancid lard and suet until the proper tint is obtained. A method of preparing mercurial ointment proposed by Orosi is to precipitate metallic mercury, in the pulverulent form, from a solution of corrosive sublimate, by an excess of stannous chloride, with the addition of hydrochloric acid, and, having poured off the supernatant fluid, washed the precipitate with warm water, and dried it between bibulous paper, to incorporate it with the prescribed proportion of lard. To prevent the precipitated mercury from running into globules, it is recommended to cover with fat the interior of the vessel in which the precipitation takes place. For an account of many expedients that have been proposed to facilitate the extinguishment of the metal, see a paper by Dieterich. (*A. J. P.,* 1880.)

Mercurial ointment has when freshly prepared a bluish color, which becomes darker with age. It has been thought to contain the mercury in the state of mercurous oxide, but most of the metal can be separated by methods not calculated to reduce the oxide, and it is now generally admitted that by far the greater part of it exists in a state of minute division and not of chemical combination. It has been shown, however, that the metal is slightly oxidized, and the change of color which the ointment undergoes with age is attributable to further oxidation. If the ointment be kept long melted in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. After this has been filtered so as to separate everything undissolved, it is blackened by hydrogen sulphide, and yields a trace of mercurial oxide to acetic acid. Christison states that he has examined various samples of the ointment, and never failed to detect mercurial oxides, and he has inferred from his observations that the oxide amounts to rather more than 1 per cent. But the proportion is variable, according to the age and mode of preparation of the ointment. It scarcely admits of a doubt that the mercurial oxide formed enters into chemical combination with the lard or one of its fatty acids. Donovan advanced the idea that the medicinal activity of the ointment depended exclusively on this compound of the lard with the mercurial oxide. An ointment made by merely mixing lard and black mercurial oxide has not the same effect, however, because there is no chemical union between the ingredients. But upon exposing such a mixture to a temperature of 176.6° C. (350° F.), and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide, and the resulting compound was proved to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. It has been proposed to substitute an ointment thus prepared for that made according to the official directions, as being more manageable and of more uniform strength. Care, however, would be required in preparing it to avoid a temperature either too high or too low, as the former might decompose the oxide, and

the latter would be insufficient to effect its union with the lard. There would be danger, also, that the lard might be rendered irritant by the influence of the heat, or if subjected to high summer temperatures will become unequal in strength in consequence of the settling of the metallic ingredient. The inference is that, after long standing, the contents of the jar should be triturated, so as to restore an equable strength, before being dispensed or always kept in a cool place. (*A. J. P.*, xvi, 2.)

Uses.—Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the general effects of mercury upon the system, but is used almost exclusively in the treatment of *syphilis*. Half to one drachm may be used at each application. It has also been employed as a resolvent in local affections, as in the case of *venereal buboes*, and of *chronic glandular swellings*, with the thought that it may operate directly by being applied in the course of the absorbents passing through the enlarged glands.

It is best absorbed if applied over those areas of the body where the skin is thin, as the bend of the elbows or knees, or the groins. The friction should on each occasion be continued till the ointment is not visible on the skin. When frequently rubbed upon the same part, it is prone to produce a disagreeable eruption, which interferes with its continued application, and it is therefore advisable to apply it to different parts if used on successive days. Mercurial ointment has been employed, with some success, to prevent the maturation of the *small pox pustule*, and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of air to the covered part. To be successful it must be applied before the third or fourth day of the eruption. The ointment has been recommended also in *erysipelas* and in *chilblains*. Potassium iodide rubbed with mercurial ointment is said to promote the separation of the mercury in the form of globules (*J. P. C.*, 3e sér., x, 356); but the effect will not take place if the iodide has been throughly dried and well powdered and the ointment is added to it in small portions at a time. (*Ibid.*, x, 421.)

Off. Prep.—Linimentum Hydrargyri, *Br.;* Unguentum Hydrargyri Compositum, *Br.;* Unguentum Hydrargyri Dilutum, *U. S.*

UNGUENTUM HYDRARGYRI AMMONIATI. U. S., Br.

OINTMENT OF AMMONIATED MERCURY Ung. Hydrarg. Ammon. [White Precipitate Ointment]

(ụn-guĕn'tŭm hȳ-drär'gy-rī ạm-mō-nī-ā'tī)

Unguentum Præcipitati Albi; Ointment of White Precipitate; Pommade de Chloramidure de Mercure, *Fr.;* Unguentum Hydrargyri Album, *P. G.;* Weisse Quecksilbersalbe, *G.*

* "Ammoniated Mercury, in very fine powder, *ten grammes* [or 154 grains]; White Petrolatum, *fifty grammes* [or 1 ounce av., 334 grains]; Hydrous Wool-Fat, *forty grammes* [or 1 ounce av., 180 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the ammoniated mercury with an equal weight of the melted white petrolatum, then add the remainder of the melted white petrolatum, mix thoroughly with the hydrous wool-fat, and stir the mixture until it congeals." *U. S.*

"Ammoniated Mercury, in powder, 5 *grammes;* Benzoated Lard, 95 *grammes*. Triturate the Ammoniated Mercury with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment is of approximately one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

The Br. Pharm., 1914, reduced the strength of this ointment one-half. Used chiefly as a stimulant and parasiticide in cutaneous eruptions, such as *scabies, ringworm, chronic eczema,* and *porrigo.*

UNGUENTUM HYDRARGYRI COMPOSITUM. Br.

COMPOUND MERCURY OINTMENT

(ụn-guĕn'tŭm hȳ-drär'gy-rī cọm-pŏs'ị-tŭm)

Pommade mercurielle comosée, *Fr.;* Kamper Quecksilbersalbe, *G.*

"Mercury Ointment, 40 *grammes;* Yellow Beeswax, 24 *grammes;* Olive Oil, 24 *grammes;* Camphor, in flowers, 12 *grammes*. Mix the Yellow Beeswax, Olive Oil, and Mercury Ointment with the aid of heat; add the Camphor; triturate until cold. This Ointment is of approximately three-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta,* and *Oleum Olivæ*)." *Br.*

The addition of camphor to mercurial ointment has been thought to soften it and promote absorption of the mercury, but that it has such an effect is very doubtful.

UNGUENTUM HYDRARGYRI DILUTUM. U. S.

DILUTED MERCURIAL OINTMENT Ung. Hydrarg. Dil. [Blue Ointment Hydrargyri unguentum P. I.]

(ụn-guĕn'tŭm hȳ-drär'gy-rī dī-lū'tŭm)

* "Mercurial Ointment, *six hundred grammes* [or 21 ounces av., 72 grains]; Petrolatum, *four hundred grammes* [or 14 ounces av., 48 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix them thoroughly. For use in southern latitudes or during the warm season in other localities, 50 Gm. of the petrolatum (or more, if necessary) may be replaced by an equal quantity of yellow wax.

"**Assay.**—Proceed as directed in the assay under *Unguentum Hydrargyri.* The separated mercury weighs not less than 2.9 Gm. nor more than 3.1 Gm." *U. S.*

This ointment was introduced into the U. S. P. (8th Rev.) to correspond to the recommenda-

tions of the International Conference; it should be kept in a cool place in the summer, as otherwise the mercury may separate on account of the softening of the fatty vehicle.

A substitute for *blue ointment* has been proposed by a French pharmacist, which is made as follows: 23.5 Gm. of mercuric chloride is triturated with 8.1 Gm. of sodium sulphocyanate and enough lanolin and petrolatum to make 100 Gm. The sulphocyanate reduces the mercuric chloride with the production of metallic mercury in a finely divided state and the resulting preparation is said to be very similar in its effect to blue ointment and to be much more easily prepared. (*Bull. Pharm.*, 1914, 306.)

UNGUENTUM HYDRARGYRI IODIDI RUBRI. Br.

MERCURIC IODIDE OINTMENT

(ụn-guĕn'tŭm hȳ-drär'gy-rī ī-ŏd'ī'dī rū'brī)

Ointment of Mercuric Iodide; Ointment of Red Iodide of Mercury; Pommade d'Iodure Mercurique, Pommade de Deutoiodure de Mercure, *Fr.*; Jodquecksilbersalbe, *G.*

"Red Mercuric Iodide, in powder, 4 *grammes;* Benzoated Lard, 96 *grammes.* Triturate the Red Mercuric Iodide with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This ointment is employed as a dressing to indolent *scrofulous* and *syphilitic ulcers.*

UNGUENTUM HYDRARGYRI NITRATIS. U. S., Br.

OINTMENT OF MERCURIC NITRATE Ung. Hydrarg. Nit. [Citrine Ointment]

(ụn-guĕn'tŭm hȳ-drär'gy-rī nī-trā'tĭs)

Ointment of Nitrate of Mercury; Unguentum Citrinum; Unguentum Hydrargyri Citrinum; Pommade Citrine, *Fr. Cod.*; Onguent Citrin, Pommade de Nitrate de Mercure, *Fr.*; Quecksilbernitratsalbe, Gelbe Quecksilbersalbe, *G.*

* "Mercury, *seven grammes* [or 108 grains]; Nitric Acid, *seventeen and five-tenths grammes* [or 271 grains]; Lard, free from water, *seventy-six grammes* [or 2 ounces av., 298 grains], to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Warm the lard in a capacious porcelain dish until it has just melted, or to about 45° C. (113° F.). Add *seven grammes* [or 108 grains] of the nitric acid all at once and continue the heat until the characteristic reaction is complete. Hold an inverted glass funnel over the dish to protect the operator from any lard spurting from the dish during the reaction. Withdraw the heat immediately after the rapid rise of froth which accompanies the end reaction and cool the treated lard, stirring it until it assumes a bright citrine color. Dissolve the mercury in the remainder of the nitric acid, warming it if necessary to prevent crystallizing, and mix the solution with the previously prepared lard. All contact with metallic utensils or containers must be avoided." *U. S.*

"Mercury, 10 *grammes;* Nitric Acid, 30 *millilitres;* Prepared Lard, 40 *grammes;* Olive Oil, 70 *grammes.* Dissolve the Mercury in the Nitric Acid without the aid of heat, shaking gently from time to time. Heat the Prepared Lard and Olive Oil together on a sand-bath, so that the mixture when transferred to a heated earthen jar, capable of holding ten times the quantity, is at a temperature of about 150° C. (302° F.). Add the cold mercurial solution very gradually, stirring constantly with a glass or wooden spatula to promote the disengagement of fumes. Keep the mixture at a temperature of not less than 90° C. (194° F.) until frothing ceases, then stir until cold. (See Appendix XII, Part III, *Unguenta,* and page 779, *Oleum Olivæ.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The formula for this ointment was changed in the U. S. P. (8th Rev.) by replacing the lard oil with lard; this in our opinion is not an improvement, as the present ointment is too hard in cold weather and more disposed to granulate than the ointment of the U. S. P. 1890. The introduction of a diluted citrine ointment into the Pharmacopœia similar to the one in the British Pharmacopœia would prove a great convenience.

The chemical changes which take place in the preparation of this ointment are not precisely known. They differ somewhat according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. In the British process and that of the U. S. P. 1870 the mercury, in the first step of the process, is converted into a mixture of mercuric and mercurous nitrate by the addition of nitric acid in excess, with the loss of some of the free nitric acid through deoxidation. When the acid mercurial solution is added to the fatty matter, a reaction takes place, which results in the fat being oxidized at the expense of the free nitric acid, nitrogen dioxide and nitrogen tetroxide being at the same time liberated, and the olein of the fat is converted into elaidin, which change is recognized by the beautiful orange color of the fat. But the degree to which these changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low, there is little or no escape of gas; if elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As formerly prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon began to change, acquiring in time a dirty-greenish and mottled color, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results were ascribed to various causes, and many different modifications of the process were pro-

posed in order to obviate them. The present official process was based on Rother's formula (*A. J. P.*, xlii, 420), and the value of this process lies principally in the fact that the olein of the oil is first converted into elaidin by the addition of nitric acid alone and the application of heat, and when the reaction has ceased and the basis of citrine ointment, as it might be called, is prepared, and nearly cold, the mercurial solution is added. In this way decomposition of the mercuric nitrate is avoided, as it is not subjected to heat, and the result is an ointment which will retain its color and consistence a long time. The drying vegetable oils appear, like olive oil, to be converted by nitrous acid or mercuric nitrate into elaidin, and it was a fair inference that they might be employed advantageously in the preparation of citrine ointment. Accordingly, Fessenden of North Carolina, stated, in an inaugural essay, that he substituted linseed oil for the neat's-foot oil, and succeeded in obtaining a perfectly good and durable ointment. Faliéres has found the oil of the ground nut (*Arachis hypogæa*) to answer very well. (*P. J.*, 1873, p. 1031.) Purified cotton seed oil makes an excellent vehicle. Washed butter has been used as the fat.

In the British process, when the fatty matter and the mercurial solution are mixed, care must be taken that the heat applied be not too great. Gas is extricated at 82.2° C. (180° F.), and at 100° C. (212° F.) escapes so abundantly that the mixture boils over unless the vessel is very large. (Alsop.) Besides, if the heat be too great, a portion of the mercury will be reduced, and the color of the ointment impaired. When large quantities of materials are operated upon, the reaction which occurs produces of itself a sufficient heat, but in ordinary cases the temperature should be kept at about 87.7° C. (190° F.) by means of a water bath, and if it exceed 96.1° C. (205° F.) should be reduced. It should always be sufficient to produce a copious extrication of gas. The ointment should be prepared in a glass, porcelain, or well-glazed earthen vessel, and a glass rod or a wooden spatula should be employed for stirring the mixture. Under no circumstances should an iron or steel spatula or stirrer be used in its preparation, because of the discoloration due to the action of the acid upon the iron.

The U. S. P. IX process is well adapted to small lots of the ointment but the reaction is too violent for large quantities. When large amounts are to be prepared mix the melted lard and acid in an earthenware crock of at least twice the size required to hold the ointment, place it in a water bath and warm it until the reaction begins. Then withdraw most of the heat and allow the reaction to proceed for some hours or until complete. Finally incorporate the solution of mercuric nitrate. If the reaction should become too violent it may be checked by adding cold water which will afterwards separate.

Uses.—This ointment is much and very advantageously employed, as a stimulant and alterative application, in *porrigo* or *tinea capitis*, *impetigo larvalis*, *psoriasis*, *sycosis*, *pityriasis*, certain forms of *chronic eczema*, and various other eruptive affections. It is an active parasiticide and antiseptic, highly stimulating and generally should be diluted with lard, unless in very sluggish cases. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied. An ointment prepared with lard and nitric acid, called *Alyon's ointment*, after the person who first prepared it, was formerly much used in cases similar to those in which the citrine ointment is now employed. The *ointment of nitric acid* of the former Edinburgh and Dublin Pharmacopœias was of this character.

Off. Prep.—Unguentum Hydrargyri Nitratis Dilutum, *Br.*

UNGUENTUM HYDRARGYRI NITRATIS DILUTUM. Br.

DILUTED MERCURIC NITRATE OINTMENT [Diluted Ointment of Nitrate of Mercury]

(ụn-guĕn'tŭm hȳ-drär'gy-rī nī-trā'tĭs dī-lū'tŭm)

"Mercuric Nitrate Ointment, 20 *grammes;* Soft Paraffin, yellow, 80 *grammes.* Mix by trituration." *Br.*

UNGUENTUM HYDRARGYRI OLEATI. Br.

MERCURIC OLEATE OINTMENT

(ụn-guĕn'tŭm hȳ-drär'gy-rī ō-lẹ-ā'tī)

Pommade d'Oléate Mercurique, *Fr.;* Quecksilberoleatsalbe, *G.*

"Oleated Mercury, 25 *grammes;* Benzoated Lard, 75 *grammes.* Mix by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

UNGUENTUM HYDRARGYRI OXIDI FLAVI. U. S., Br.

OINTMENT OF YELLOW MERCURIC OXIDE
Ung. Hydrarg. Oxid. Flav.

(ụn-guĕn'tŭm hȳ-drär'gy-rī ŏx'ĭ-dī flā'vī)

Yellow Mercuric Oxide Ointment; Pommade d'oxyde mercurique jaune, *Fr.;* Gelbe Quecksilberoxydsalbe, *G.*

* "Yellow Mercuric Oxide, in very fine powder, *ten grammes* [or 154 grains]; Water, *ten grammes* [or 154 grains]; Hydrous Wool Fat, *forty grammes* [or 1 ounce av., 180 grains]; Petrolatum, *forty grammes* [or 1 ounce av., 180 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the yellow mercuric oxide with the water until the mixture is perfectly smooth, then add the hydrous wool fat in divided portions, and incorporate thoroughly with the petrolatum. All contact with metallic utensils or containers must be avoided." *U. S.*

"Yellow Mercuric Oxide, in powder, 2 *grammes;* Soft Paraffin, yellow, 98 *grammes.* Triturate the Yellow Mercuric Oxide with a

portion of the Soft Paraffin until smooth; gradually add the remainder, mixing thoroughly by trituration." *Br.*

The unctuous vehicle of this ointment, without being so liquid as to allow the powder to subside, must yet melt at the heat of the body, and thus, when introduced into the eye, spread equably over the surface. It should, moreover, be as far as possible chemically indifferent to the oxide, and, while perfectly bland in its proper state, should not be liable to become irritating by rancidity.

Uses.—This is the least irritant of the official ointments of the mercurial salts. It possesses the disinfectant and local stimulating properties of the mercury preparations and is used in various skin diseases, especially in *eczema* of the auditory canal or eye-lid, and in *hordeolum.* The U. S. ointment generally requires dilution, the British being of a more frequently used strength.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. Br.

RED MERCURIC OXIDE OINTMENT [Red Precipitate Ointment]

(ŭn-guĕn'tŭm hȳ-drär'gy-rī ŏx'ĭ-dī rū'brī)

Unguentum Præcipitati Rubri; Pommade d'oxyde rouge de Mercure, *Fr. Cod.*; Pommade de Lyon, Pommade de Précipité rouge, Baume ophthalmique rouge, *Fr.*; Unguentum Hydrargyri Rubrum, *P. G.*; Rothe Quecksilbersalbe, *G.*

"Red Mercuric Oxide, in powder, 10 *grammes;* Paraffin Ointment, yellow, 90 *grammes.* Melt the Paraffin Ointment; sift in the Red Mercuric Oxide; stir until cold." *Br.*

Red Precipitate Ointment was deleted from the U. S. P. IX but has been added to the N. F. (see Part III). It has been largely replaced in medical practice by Yellow Mercuric Oxide Ointment, which is a more desirable preparation.

The red mercuric oxide here referred to is that prepared from the nitrate and usually called *red precipitate.* It is important that the oxide should be thoroughly pulverized before being mixed with the lard, as otherwise it might prove injurious in cases of ophthalmia, in which it is sometimes used. When great care is taken to have the red oxide very finely pulverized, the color is more yellowish than is usual. This ointment loses its fine red color when long kept, probably in consequence of the conversion of the red oxide into the black, or its reduction to the metallic state. It is best to prepare it in small quantities at a time. The U. S. P. (8th Rev.) process was an improvement over the process of the U. S. P. 1890, particularly in the choice of the vehicle.

Ointment of red mercuric oxide is more highly stimulating than that of the yellow oxide. It is employed in *indolent and foul ulcers,* and *various skin diseases.* It is less frequently employed than the ointment of yellow mercuric oxide, because the latter can be made smoother and less irritating, and has the same chemical composition and properties. It may be diluted with lard if found too stimulating.

UNGUENTUM HYDRARGYRI SUBCHLORIDI. Br.

MERCUROUS CHLORIDE OINTMENT [Calomel Ointment]

(ŭn-guĕn'tŭm hȳ-drär'gy-rī sŭb-klō'rī-dī)

Unguentum Calomelanos, *Br.* 1864; Ointment of Subchloride of Mercury; Ointment of Calomel; Pommade de Chlorure Mercureux, Pommade de Calomel, Pommade de Calomélas, *Fr.*; Quecksilberchlorürsalbe, *G.*

"Mercurous Chloride, 20 *grammes;* Benzoated Lard, 80 *grammes.* Triturate the Mercurous Chloride with a portion of the Benzoated Lard, until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment is of twice the strength of the corresponding preparation of the British Pharmacopœia, 1898. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

Uses.—While ointments of calomel are often of much value in the same class of cases for which the yellow oxide is employed, this ointment is far too strong. We believe ointments of this character might well be left to extemporaneous prescription.

UNGUENTUM IODI. U. S., Br.

IODINE OINTMENT Ung. Iodi

(ŭn-guĕn'tŭm ī-ō'dī)

Unguentum Iodinii, *U. S.* 1870; Pommade d'iodure de potassium ioduré, *Fr. Cod.*; Pommade d'Iode, *Fr.*; Jodsalbe, *G.*

* "Iodine, *four grammes* [or 62 grains]; Potassium Iodide, *four grammes* [or 62 grains]; Glycerin, *twelve grammes* [or 185 grains]; Benzoinated Lard, *eighty grammes* [or 2 ounces av., 360 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the iodine and potassium iodide in a glass mortar with the glycerin until dissolved, then gradually incorporate the benzoinated lard and mix thoroughly. All contact with metallic utensils or containers must be avoided. This Ointment must not be dispensed unless it has been recently prepared." *U. S.*

"Iodine, 4 *grammes;* Potassium Iodide, 4 *grammes;* Glycerin, 12 *grammes;* Prepared Lard, 80 *grammes.* Triturate the Iodine, Potassium Iodide, and Glycerin in a glass or porcelain mortar; add the Prepared Lard; mix thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The object of the potassium iodide and water in the U. S. 1890 process was to bring the iodine into a state in which it may be equably incorporated with the lard. They were found to answer better in practice than the alcohol formerly used, but glycerin answers still better and is used in both Pharmacopœias.

Miles Shimer (*Proc. P. P. A.*, 1915, p. 304) suggests that by keeping the iodine, potassium iodide and glycerin already made up as a stock

solution, the dispensing of U. S. P. iodine ointment is much more expeditiously accomplished.

The proportion of potassium iodide was increased from 1 Gm. to 4 Gm. in the U. S. P. VIII and glycerin (12 per cent.) added. When rubbed upon the skin it imparts to it an orange color, which, however, slowly disappears with the absorption of the iodine.

Uses.—Ointment of Iodine is useful both for the local counter-irritant effect of the element and as a means of obtaining the constitutional action of the iodides. It is commonly believed that this ointment exercises a local resolvent action and it is therefore employed in various forms of *arthritis, goitre, scrofulous swellings of the glands,* and other *chronic tumefactions.* When continued for some time it occasionally produces a pustular eruption upon the portion of skin to which it is applied. It has also been recommended in *chilblains.* The ointment should be prepared only when wanted for use, for it undergoes change if kept, losing its deep orange-brown color, and becoming pale upon its surface, due to the combination of part of the iodine with the fat.

UNGUENTUM IODOFORMI. U. S., Br.

IODOFORM OINTMENT Ung. Iodof.

(ŭn-guĕn'tŭm ī-ō-dō-fôr'mī)

Pommade d'Iodoforme, *Fr.*; Jodoformsalbe, *G.*

* "Iodoform, in very fine powder, *ten grammes* [or 154 grains]; Benzoinated Lard, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the iodoform thoroughly with about twice its weight of the benzoinated lard, then incorporate the remainder of the benzoinated lard." *U. S.*

"Iodoform, in powder, 10 *grammes;* Prepared Lard, 90 *grammes.* Triturate the Iodoform with a portion of the Prepared Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

It is important to have the iodoform in very fine powder, as officially directed, and, owing to the powerful odor of iodoform, it is usual to add oil of bitter almond or one of the other volatile oils, balsam of Peru, or a similar substance, to render the odor more bearable.

UNGUENTUM LANÆ COMPOSITUM. Br.

COMPOUND WOOL FAT OINTMENT [Emollient Ointment]

(ŭn-guĕn'tŭm lā'næ cŏm-pŏs'ĭ-tŭm)

"Prepared Lard, 40 *grammes;* Wool Fat, 40 *grammes;* Paraffin Ointment, 20 *grammes.* Melt together; stir until cold. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The addition of the paraffin ointment to woolfat overcomes the stickiness which is so frequently an obstacle to the employment of that emollient.

UNGUENTUM MYROBALANI. Br.

MYROBALAN OINTMENT

(ŭn-guĕn'tŭm mȳ-rō-bă-lā'nī)

"Myrobalans, in powder, 20 *grammes;* Benzoated Lard, 80 *grammes.* Triturate the Myrobalans with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This is used as a local astringent.

Off. Prep.—Unguentum Myrobalani cum Opio, *Br.*

UNGUENTUM MYROBALANI CUM OPIO. Br.

MYROBALAN AND OPIUM OINTMENT

(ŭn-guĕn'tŭm mȳ-rō-bă-lā'nī cum ōp'ĭ-ō)

"Myrobalan Ointment, 92.5 *grammes;* Opium, in powder, 7.5 *grammes.* Triturate the Opium with a portion of the Myrobalan Ointment until smooth; gradually add the remainder, mixing thoroughly by trituration. This Ointment contains 7.5 per cent. of Opium." *Br.*

UNGUENTUM PARAFFINI. Br.

PARAFFIN OINTMENT

(ŭn-guĕn'tŭm păr-ăf-fī'nī)

Pommade de Paraffin, *Fr.*; Paraffinsalbe, *G.*

"Hard Paraffin, 27 *grammes;* Soft Paraffin, 70 *grammes;* White Beeswax, 3 *grammes.* Melt together; stir until cold. When Paraffin Ointment is used as the basis of white ointments it should be prepared with the white variety of Soft Paraffin; and when used for colored ointments it should be prepared with the yellow variety of Soft Paraffin. (See Appendix XII, Part III, *Unguenta.*)" *Br.*

This was recognized by the Br. Ph. 1898 for use as a vehicle in the exhibition of various medicaments.

UNGUENTUM PHENOLIS. U. S. (Br.)

OINTMENT OF PHENOL Ung. Phenol. [Unguentum Acidi Carbolici, U. S. 1890, Ointment of Carbolic Acid]

(ŭn-guĕn'tŭm phē-nō'lĭs)

Unguentum Acidi Carbolici, *Br.*; Pommade de Phénol, Pommade Phéniquée, Pommade d'Acide phénique, *Fr.*; Karbolsalbe, Phenolsalbe, *G.*; Carbolized Petrolatum.

* "Liquefied Phenol, *two and twenty-five hundredths grammes* [or 35 grains]; Ointment, *ninety-seven and seventy-five hundredths grammes* [or 3 ounces av., 196 grains], to make *one hundred grammes* [or 3 ounces av., 231

grains]. Add the liquefied phenol to the melted ointment and stir the mixture until it begins to congeal." *U. S.*

"Phenol, 3 *grammes;* Paraffin Ointment, white, 97 *grammes.* Melt the Paraffin Ointment; in it dissolve the Phenol; stir until cold." *Br.*

The quantity of phenol in this ointment was decreased from 10 per cent. in the U. S. P. 1880 to 5 per cent. in the 1890 revision, and has been further decreased to 2.25 per cent. in the U. S. P. IX. This is an improvement, for it is a very strong ointment, which for most purposes still requires dilution.

Its value as a disinfectant is greatly overestimated, for phenol exerts its full anti-bacterial powers only when in aqueous solution.

UNGUENTUM PICIS LIQUIDÆ. U. S., Br.

TAR OINTMENT Ung. Pic. Liq.

(ụn-guĕn'tŭm pī'cĭs lĭq'uị-dæ)

Pommade de Goudron, *Fr. Cod.;* Theersalbe, *G.*

* "Tar, *five hundred grammes* [or 17 ounces av., 279 grains]; Yellow Wax, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Lard, *three hundred and fifty grammes* [or 12 ounces av., 151 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the yellow wax, add the lard, and to the melted mixture add the tar, previously warmed, and incorporate thoroughly; strain through muslin, and stir the mixture until it congeals." *U. S.*

"Tar, 70 *grammes;* Prepared Lard, 5 *grammes;* Yellow Beeswax, 25 *grammes.* Melt together; stir until cold. (See Appendix XII, *Unguenta.*) In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The formula for tar ointment in the U. S. P. 1890 differed from that formerly official in the use of yellow wax and lard in place of suet. The same ingredients were retained in the Eighth Revision, but the proportion of wax was slightly decreased, making the ointment somewhat softer in consistence. This ointment is highly useful as a stimulant application in various *scaly* and *scabby eruptions,* particularly in *psoriasis* and *chronic eczema* and also for its antiparasitic effect in *tinea capitis* or similar *skin diseases.* In the last-mentioned affection it should be applied night and morning, and in bad cases the patient should constantly wear a cap thickly coated internally with the ointment. In some cases it requires dilution with an equal quantity of lard to avoid irritation.

UNGUENTUM PLUMBI IODIDI. Br.

LEAD IODIDE OINTMENT

(ụn-guĕn'tŭm plŭm'bī ī-ŏd'ị-dī)

Lead Iodide Ointment; Pommade d'Iodure de Plomb, *Fr. Cod.;* Jodbleisalbe, *G.*

"Lead Iodide, in powder, 10 *grammes;* Benzoated Lard, 90 *grammes.* Triturate the Lead Iodide with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

For the uses of this ointment, see *Plumbi Iodidum.* It is also official in the N. F. IV (see Part III).

UNGUENTUM PLUMBI SUBACETATIS. Br.

LEAD SUBACETATE OINTMENT

(ụn-guĕn'tŭm plŭm'bī sŭb-ă-cẹ-tā'tĭs)

Cerate of Subacetate of Lead was not admitted to the U. S. P. IX, but has been included in the N. F. IV (see Part III).

"Strong Solution of Lead Subacetate, 12.5 *grammes;* Wool Fat, 25.0 *grammes;* Hard Paraffin, 12.5 *grammes;* Soft Paraffin, 50.0 *grammes.* Melt together the Wool Fat and the Hard and Soft Paraffins; stir until nearly cold; add the Strong Solution of Lead Subacetate, and continue to stir until cold." *Br.*

The white petrolatum, wool fat and paraffin now used in this ointment are preferable to the lard and cottonseed oil formerly employed, as they are free from the great objections to the former official cerate, of proneness to rancidity, and discoloration. This cerate received the name by which it is commonly known from Goulard, by whom it was employed and recommended.

The ointment of subacetate of lead was formerly largely used in *excoriations, burns, scalds,* and *chilblains,* but is infrequently employed at present.

UNGUENTUM POTASSII IODIDI. Br.

POTASSIUM IODIDE OINTMENT

(ụn-guĕn'tŭm pọ-tăs'sĭ-ī ī-ŏd'ị-dī)

Ointment of Potassium Iodide; Pommade d'Iodure de Potassium, *Fr. Cod.;* Unguentum Kalii jodati, *P. G.,* Jodkaliumsalbe, Kaliumjodidsalbe, *G.*

"Potassium Iodide, 10.0 *grammes;* Potassium Carbonate, 0.6 *gramme;* Distilled Water, 9.4 *grammes;* Benzoated Lard, 80.0 *grammes.* Dissolve the Potassium Iodide and Potassium Carbonate in the Distilled Water; mix the solution, gradually, with the Benzoated Lard, in a slightly warmed mortar. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

The former ointments of potassium iodide became discolored by time in consequence of the liberation of iodine. This was due to rancidity in the lard, and the slightest change in the fat would produce some discoloration. It was prevented in the U. S. P. 1880 by the sodium thiosulphate, which also produces traces of sodium iodide and sulphur. The addition of potassium carbonate by the present Br. Pharmacopœia is made with the same object.

The *Bulletin de Pharmacie du Nord* recommended a concentrated solution of potassium iodide in glycerin as a basis for this ointment. One gramme of the salt is dissolved in two and a half grammes of hot glycerin, and the solution mixed with the fatty constituent in the proper proportion. The advantages of this method are that the ointment is free from crystals, and the salt more readily absorbed. The glycerin would probably not be objectionable in most cases, and potassium carbonate could be added, if desired. Ointment of potassium iodide is employed for the discussion of *goitres, scrofulous tumors,* and other *indolent swellings,* and is sometimes preferred to the ointment of iodine, as it does not, like that, discolor the skin. It does not, however, possess the antiseptic nor counter-irritant properties of the free iodine.

UNGUENTUM STAPHISAGRIÆ. Br.

STAVESACRE OINTMENT

(ụn-guĕn'tŭm stăph-ĭ-să'grĭ-æ)

Onguent de Staphisaigre, *Fr.*; Stephanskörnersalbe, *G.*

"Stavesacre Seeds, 20 *grammes;* Yellow Beeswax, 10 *grammes;* Benzoated Lard, 85 *grammes.* Crush the Stavesacre Seeds; digest the crushed seeds with the Benzoated Lard on a water-bath for two hours; strain and press through calico; melt the Beeswax in the liquid mixture; stir until cold. (See Appendix XII, Part III, *Unguenta.*) In India, Prepared Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

This ointment is but half the strength of that official in the British Pharmacopœia 1885; it is said to be non-irritant, and is largely used in Great Britain for destroying *body-lice,* also in *scabies* and *prurigo.*

UNGUENTUM STRAMONII. U. S.

STRAMONIUM OINTMENT Ung. Stramon.

(ụn-guĕn'tŭm strą-mō'nĭ-ī)

Pommade de Stramoine, *Fr.*; Stechapfelsalbe, *G.*

* "Pilular Extract of Stramonium, *ten grammes* [or 154 grains]; Diluted Alcohol, *five mils* [or 81 minims]; Hydrous Wool Fat, *twenty grammes* [or 308.6 grains]; Benzoinated Lard, *sixty-five grammes* [or 2 ounces av., 128 grains], to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the extract with the diluted alcohol until a smooth mixture is obtained; with this incorporate the hydrous wool fat, then add the benzoinated lard, and mix thoroughly." *U. S.*

This is a more certain preparation than that of the former editions of the U. S. Pharmacopœia, which was made by boiling the fresh leaves in lard. The color of the ointment of the U. S. P. IX is different from that of the earlier Pharmacopœias, the greenish tint being due to the use of official extract of stramonium which is now made from the leaves instead of the seeds. For remarks by A. P. Sharp of Baltimore, on the preparation of this ointment, see *A. J. P.* (xxvii, 391). A useful anodyne application in *irritable ulcers, painful hemorrhoids,* and *bruises.*

UNGUENTUM SULPHURIS. U. S., Br.

SULPHUR OINTMENT Ung. Sulphur.

(ụn-guĕn'tŭm sŭl'phŭ-rĭs)

Pomatum Sulfuratum, Unguentum Sulfuratum Simplex; Pommade Soufrée, *Fr. Cod.*; Schwefelsalbe, *G.*

* "Sublimed Sulphur, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Benzoinated Lard, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the sublimed sulphur with the benzoinated lard, gradually added, until they are thoroughly mixed." *U. S.*

"Sublimed Sulphur, 10 *grammes;* Benzoated Lard, 90 *grammes.* Triturate the Sublimed Sulphur with a portion of the Benzoated Lard until smooth; gradually add the remainder, mixing thoroughly by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

Washed sulphur was substituted in the U. S. P., 1890, for the sublimed sulphur of the former Pharmacopœia; the change was of questionable utility and the U. S. P. IX has again returned to the use of sublimed sulphur. It has been found that the acid products resulting from the slight decomposition in sublimed sulphur have value as parasiticides. In the U. S. P. VIII the percentage of sulphur was reduced one-half. Its disagreeable odor may be partially concealed by oil of lemon or oil of bergamot.

This ointment affords a ready means of obtaining the local action of sulphur. For discussion of its properties, see *Sulphur.*

UNGUENTUM ZINCI OLEATIS. Br.

ZINC OLEATE OINTMENT

(ụn-guĕn'tŭm zĭn'cī ō-lę-ā'tĭs)

Pommade d'oléate de zinc, *Fr.*; Zinkoleatsalbe, *G.*

"Zinc Sulphate, 30 *grammes;* Hard Soap, in shavings, 90 *grammes;* Distilled Water, boiling, Soft Paraffin, white, of each *a sufficient quantity.* Dissolve the Zinc Sulphate in sixty millilitres of the Distilled Water. Dissolve the Hard Soap in six hundred millilitres of the Distilled Water. Mix the solutions; heat to boiling; allow the melted zinc oleate so produced to rise to the surface; cool until it solidifies; pour off the aqueous liquid; boil the zinc oleate with successive quantities of Distilled Water until the washings afford not more than a slight *reaction* for sulphates; reduce the cake thus obtained to a coarse powder; dry at a temperature below 60° C. (140° F.); melt on a water-bath with an equal weight of the Soft Paraffin; stir until cold." *Br.*

This ointment was radically changed in the Br. Ph., 1898, revision; instead of using zinc oleate made from oleic acid and zinc oxide, a process is ordered which directs the zinc oleate to be made by double decomposition between zinc sulphate and sodium oleo-stearate (hard soap). The product is a white, fine precipitate; it is, however, not a pure oleate, but a zinc oleo-stearate or oleo-palmitate.

This preparation has therapeutic properties similar to those of the ointment of zinc oxide, but is a little more stimulating. It is especially useful in *chronic eczema* and similar *cutaneous eruptions.*

UNGUENTUM ZINCI OXIDI. U. S. (Br.)

OINTMENT OF ZINC OXIDE Ung. Zinc. Ox. [Zinc Ointment]

(ŭn-guĕn'tŭm zĭn'cī ŏx'ĭ-dī)

Unguentum Zinci, *Br.;* Ointment of Zinc; Unguentum de Nihilo Albo; Pommade d'Oxyde de Zinc, Cérat épulotique, *Fr.;* Unguentum Zinci, *P. G.;* Zinksalbe, *G.*

* "Zinc Oxide, in very fine powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Benzoinated Lard, *eight hundred grammes* [or 28 ounces av., 96 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the zinc oxide, which must be free from gritty particles, with about one-fourth of the melted benzoinated lard, in a previously warmed container, and with this incorporate the remainder of the benzoinated lard, previously melted. If necessary, strain the Ointment while warm, and stir it thoroughly until it congeals." *U. S.*

"Zinc Oxide, 15 *grammes;* Benzoated Lard, 85 *grammes.* Mix by trituration. (See Appendix XII, Part III, *Unguenta.*) In India, Benzoated Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making this Ointment." *Br.*

The assay of this ointment for its zinc oxide content may be easily accomplished, according to J. L. Mayer (*Proc. N. Y. P. A.*, 1913, p. 226) by igniting a weighed portion of the ointment and weighing the resulting zinc oxide. Care should be taken after combustion has begun, to withdraw the burner and allow the sample to burn quietly until all inflammable matter is consumed. If the resulting oxide is not white in color it may be moistened with nitric acid and re-ignited. The same procedure will serve for the assay of ointment of zinc stearate.

The British ointment is weaker in the proportion of zinc oxide than that of the U. S. Pharmacopœia, the former containing about 15 per cent., the latter 20 per cent. *Commercial* zinc oxide should not be used, as it is usually gritty, and it is difficult to make a smooth ointment with it; the many expedients that have been suggested by various writers, such as the use of a paint mill or of a flat iron, or trituration with oil or with glycerin, are unnecessary if official zinc oxide is employed and the directions of the Pharmacopœia followed.

This ointment enjoys an extraordinary popularity in the treatment of all sorts of inflammatory conditions of the skin, as *eczema, sunburn, sore nipples, chapped hands,* etc. It owes its value in part to the emollient action of the lard and partly to the protective and mildly astringent action of zinc oxide.

Manufacturers have often replaced the lard in this ointment with petrolatum because of the difficulty in preserving the U. S. P. product, but this substitution is not desirable as the resulting ointment is not "drying" but remains moist. The official ointment, when applied to the skin, is quickly absorbed, leaving the zinc oxide as a protective coating. The ancient *unguentum tutiæ,* or *tutty ointment,* prepared from tutty, or impure zinc oxide, has almost been forgotten.

URANII NITRAS. U. S.

URANIUM NITRATE Uran. Nit. [Uranyl Nitrate]

(ū-rā'nĭ-ī nī'trās)

"It contains not less than 98 per cent. of $UO_2(NO_3)_2 + 6H_2O$ (502.62) (uranyl nitrate). Preserve it in well-closed containers, protected from light." *U. S.*

The salts of uranium are obtained from the mineral *uraninite* or *pitchblende,* which is noteworthy from the fact that it is the mineral in which Becquerel discovered radio-active properties in 1896, which led to further investigation and the subsequent discovery of radium by the Curies about four years later (see Part III). Pitchblende consists of mixed oxides of uranium and has the formula $UO_2.2UO_3$. The salts of uranium are really not true salts of the element but are compounds of the lower oxide UO_2, and are usually called uranyl salts. Upon treating solutions of these uranyl salts with sodium hydroxide solution a yellow precipitate of sodium uranate $Na_2U_2O_7$ is produced which is of technical use in producing a variety of glass, with a peculiar yellow fluorescence, known as uranium glass.

Uranium nitrate is officially described as follows: "Uranium Nitrate occurs in the form of light yellow prisms; odorless and having a bitter, astringent taste; somewhat efflorescent; radioactive. One Gm. of Uranium Nitrate dissolves in 1.2 mils of water at 25° C. (77° F.); freely soluble in alcohol or ether. Aqueous solutions of Uranium Nitrate are yellow and acid to litmus. Separate portions of an aqueous solution of the salt (1 in 20) yield, with sodium hydroxide T.S. or ammonia water, a yellow precipitate insoluble in an excess of the reagent but soluble in ammonium carbonate T.S.; with ammonium sulphide T.S. a dark brown precipitate; and with sodium phosphate T.S. a yellow precipitate. Mix 2 mils of the aqueous solution with an equal volume of sulphuric acid, cool the mixture, and add a crystal of ferrous sulphate; a dark brown color appears around the crystal. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt (1 in 20) remains clear after the addition of an equal volume of ammonium car-

bonate T.S. (*alkaline earths*). Dilute 3 mils of this mixture to 10 mils with distilled water and add 10 mils of hydrogen sulphide T.S.; no color or precipitate is produced (*iron, manganese, or zinc*). A solution of 1 Gm. of Uranium Nitrate in 20 mils of distilled water, acidulated with 1 mil of diluted sulphuric acid, does not completely decolorize 0.1 mil of tenth-normal potassium permanganate V.S. (*uranous compounds*). An aqueous solution of the salt (1 in 100) does not at once produce a turbidity with barium chloride T.S. (*sulphate*).

"**Assay.**—Dissolve about 0.4 Gm. of the salt, accurately weighed, in 100 mils of distilled water, heat the solution to boiling, add ammonia water until no further precipitate is produced, and allow the precipitate to settle. Then wash the precipitate well on a filter with an aqueous solution of ammonium nitrate (1 in 100), and afterwards moderately ignite it in a platinum crucible, with free access of air, until the weight is constant. The urano-uranic oxide (U_3O_8) so obtained corresponds to not less than 54.8 per cent. of the weight of the salt taken, which is equivalent to not less than 98 per cent. of $UO_2(NO_3)_2 + 6H_2O$." *U. S.*

Uses.—Uranium nitrate has been used in the treatment of *diabetes mellitus* in *doses* of from one to two grains (0.065–0.13 Gm.). There is however, no sufficient reason to believe that it can influence the metabolism and any diminution which has followed its exhibition may be attributed to injury to the kidney. It is used as an indicator in the estimation of the urinary phosphates, as well as for other chemical purposes. It is incompatible with the alkaloids, chloral hydrate, salts of arsenous and phosphoric acids and changes the color of cochineal and its derivatives.

Dose, from one to two grains (0.065 to 0.13 Gm.).

URGINEA. Br.

URGINEA [Indian Squill]

(ür-gĭ'nē-ą)

"Urginea consists of the younger bulbs of Urginea indica, *Kunth,* collected soon after the plants have flowered, divested of their dry, outer, membranous coats, cut into slices, and dried. When powdered should be kept quite dry over quicklime." *Br.*

Urginea indica is a plant resembling *Urginea maritima.* It is easily distinguished from the latter in that the bulb when entire is scaly and not tunicated as the European Squill. Urginea indica grows in sandy soil near the sea coast throughout India and also extends to the lower Himalayas. The medicinal properties of the drug are apparently identical with the Squill of the Greeks. The outer coats are quite inert and should be removed as indicated in the definition of the Br. Pharm.

"Curved or sickle-shaped strips, separated or connected, several together, to a portion of the shortened axis; usually one to five centimetres long and five to ten millimetres wide; yellowish-white, fleshy, often longitudinally ribbed; tough when slightly moist, but brittle and pulverisable when dry. No odor; taste bitter and acrid." *Br.*

The bulbs of *Urginea indica* are rounded, conical or pear-shaped and about the size of an onion; tunicated, consisting of fleshy coats which enclose each other completely; color whitish; taste bitter and acrid. The bulbs of *Scilla indica* Baker, which were recognized by the Br. Add. 1900, differ in that they are not tunicated but made up of thick fleshy inbricated scales; otherwise, except that they are somewhat smaller, they resemble those of Urginea indica.

Uses.—The bulbs of Indian squill have long been used in India for purposes similar to that for which the official squill is employed in Europe and America, but no sufficient chemical examinations have been made to prove the identity of the Indian and European drugs.

Dose, one to three grains (0.065–0.2 Gm.).

UVA URSI. U. S. (Br.)

UVA URSI [Bearberry]

(ū'vą ŭr'sī)

"The dried leaves of *Arctostaphylos Uva-ursi* (Linné) Sprengel (Fam. *Ericaceæ*), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." *U. S.* "Bearberry Leaves are the dried leaves of Arctostaphylos Uva-ursi, *Spreng.*" *Br.*

Uvæ Ursi Folia, *Br.;* Barren Myrtle, Mountain Box, Rockberry; Kinnikinnic; Uva-ursi, Busserole, Raisin d'Ours, *Fr. Cod.;* Folia Uvae Ursi, *P. G.;* Bärentraube, Bärentraubenblätter, *G.;* Uva Ursina, *It.;* Gayuba, *Sp.*

The *uva ursi,* or *bearberry,* is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upward for a few inches. The leaves are scattered, upon short petioles, from half an inch to an inch long, obovate, or oblong-spatulate, acute at the base, obtuse at the apex, entire, with a rounded margin, thick coriaceous, smooth, shining, deep green on their upper surface, paler and covered with a net-work of veins beneath; furnished especially near the margin or near the midrib with minute hairs, which are usually abundant in young leaves, but may be few or absent in old leaves, especially those which have been much handled. The flowers, which stand on short reflexed peduncles, are in small clusters at the ends of the branches. The calyx is small, five-parted, reddish, and persistent. The corolla is ovate or urceolate, reddish-white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the ovary round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed,

smooth, glossy red berry, with an insipid mealy pulp and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes and high mountains of Europe, Asia, and America. On the American continent it extends from Hudson's Bay as far southward as New Jersey and Pennsylvania, in some parts of which it grows in abundance. It prefers a barren soil, flourishing on gravelly hills and elevated sandy plains. The leaves are the only part used in medicine. They are imported from Europe, but are also collected within our own limits, and the market of Philadelphia is supplied to a considerable extent from New Jersey. They should be gathered in autumn, and only the green leaves selected. In Europe the uva ursi is adulterated with the inert leaves of the *Vaccinium Vitis-Idæa* L. (*Cowberry, Mountain Cranberry*); these may be distinguished by being obovate, having revolute margins which are sometimes slightly toothed, and the presence of fine blackish dots or bristly points upon their lower surface. Leaves of the *Chimaphila umbellata* (L.) Nutt., sometimes found among the uva ursi, may be readily detected by their greater length, their cuneiform-lanceolate shape, and their serrate edges.

Arctostaphylos glauca Lindl., *manzanita,* is a small tree or shrub indigenous in California, where it generally grows in dry and rocky places on the west of the mountain ranges. The leaves appear to possess properties similar to those of the official species. (See Flint, *A. J. P.,* 1873, p. 187.) The fruit of *A. arguta* Zucco, a Mexican species, is said to be a narcotic poison.

Properties.—Uva ursi is officially described as: "Usually more or less entire, laminæ obovate or oblong-spatulate, from 12 to 30 mm. in length and from 5 to 13 mm. in breadth; summits obtuse or rounded; margins entire, slightly revolute; bases cuneate, tapering into short, stout petioles; upper surfaces dark green, glabrous and shiny, finely reticulate; under surfaces yellowish-green and slightly pubescent, especially on the midribs; coriaceous, fracture short; odor aromatic, tea-like; taste astringent and somewhat bitter. The powder is olive green; under the microscope it shows irregular fragments; epidermal cells polygonal, those of the lower surface showing broadly elliptical stomata about 0.035 mm. in length, surrounded by from 5 to 8 neighboring cells; cells of mesophyll with chloroplastids and frequently irregular masses of a carbohydrate; fragments of fibro-vascular bundles with spiral tracheæ associated with narrow, strongly lignified sclerenchymatous fibers and frequently also with crystal fibers with monoclinic prisms, from 0.006 to 0.015 mm. in diameter; numerous fragments made up of cells having a yellowish-brown content which are colored a bluish-black upon the addition of ferric chloride T.S. Place 0.1 Gm. of powdered Uva Ursi on a watch crystal and cover with another watch crystal and gently heat the powder; a crystalline sublimate forms, consisting of long rods and feather-like aggregates which polarize light with a brilliant play of colors. Macerate 1 Gm. of powdered Uva Ursi with 10 mils of boiling water, shake the mixture occasionally until cold and then filter it; the filtrate yields a grayish-purple precipitate upon the addition of a few drops of ferrous sulphate T.S." *U. S.*

"Obovate or spatulate, about two centimetres long, yellowish-green, coriaceous, entire, shortly petiolate. Upper surface glabrous, shining, reticulate; veinlets depressed. Slight odor; taste very astringent." *Br.*

The commercial drug frequently consists of the entire plants and therefore contains a large quantity of stems. The latter should not be present, according to the official definition, in greater amount than five per cent. Farwell states that the leaves are sometimes very dark or blackish-green, which is probably due to carelessness in drying. (*M. R.,* xvii, p. 35.) Holm has contributed an interesting article on the morphology of the plant. (*M. R.,* xx, p. 95.)

Uva ursi leaves contain—besides tannic and gallic acids, bitter extractive resin, gum, fatty matter, and salts of potassium and calcium—two glucosides, *arbutin,* $C_{12}H_{15}O_7$, and *ericolin,* and a resinous principle, *urson.* The tannin is so abundant (6 or 7 per cent.) that the leaves are used for tanning in Russia.

Arbutin is somewhat widely diffused in the species of Ericaceæ, such as *Chimaphila umbellata* (L.) Nutt., *Chimaphila maculata* (L.) Pursh, *Epigæa repens* L., and *Gaultheria procumbens* L. Kawalier (*Chem. Gaz.,* 1853, p. 61) obtained it from uva ursi by precipitating the decoction with lead acetate, filtering, treating the liquid with hydrogen sulphide, again filtering, evaporating to the consistence of syrup, and allowing the product to stand for several days. This gradually assumed the form of a crystalline jelly, which, being placed upon linen so as to allow the mother liquor to drain off, and then pressed, yielded nearly colorless crystals, which were purified by solution in boiling water and treatment with animal charcoal. Arbutin thus obtained is in long, acicular, colorless crystals, united in tufts, and of a bitter taste. It is soluble in water, alcohol, and ether, unchanged apparently by a heat of 100° C. (212° F.), but fusible at 167° to 168° C. (332.6°–334.4° F.), without action on vegetable colors, and not precipitated by ferric salts or by lead acetate or subacetate. It is a glucoside, being resolvable by emulsin, or more rapidly by boiling with sulphuric acid, into glucose and *hydroquinone,* $C_6H_6O_2$ (*arctuvine* of Kawalier). The occurrence of methylhydroquinone among the products of decomposition led Hlasiwetz and Habermann to give the formula $C_{25}H_{34}O_{14}$ to arbutin, but Schiff showed that this was because arbutin was almost always accompanied by *methylarbutin,* $C_{12}H_{15}(CH_3)O_7 + H_2O$. This compound has been made synthetically by Schiff (*Ber. d. Chem. Ges.,* 1882, p. 1841) by acting upon arbutin with methyliodide and potassium hydroxide in methyl alcohol solution, and purely synthetically by Michael (*Ber. d. Chem. Ges.,* 1885, p. 118) by the action of methylhydroquinone and acetochlorhydrose. It is decomposed by dilute

acids into glucose and methylhydroquinone. Upon heating 1 part of arbutin with 8 parts of manganese oxide, 2 parts of sulphuric acid, and 1 part of water, it gives off the penetrating odor of quinone. The aqueous solution is rendered blue by a small quantity of solution of ferric chloride, and green by a larger quantity. No precipitate is produced by either acids or alkalies. It blackens ammoniacal solution of silver nitrate after boiling with diluted sulphuric acid, and throws down cuprous oxide from alkaline copper solutions upon heating. It dissolves in sulphuric acid, forming a colorless solution, turning red after a short time; a trace of nitric acid turns this solution yellow-brown. An aqueous solution (1 in 20) is not changed by hydrogen sulphide. A good test for arbutin is that of Julius Jungmann, as follows: When phosphomolybdic acid is added to a solution of arbutin previously rendered alkaline by ammonia or other alkali, a blue color is produced, which is deep when the solutions are strong, but observable even when they are very dilute. (*A. J. P.*, May, 1871, p. 204.)

After the extraction of arbutin there is obtained from the mother liquor *ericolin*, $C_{34}H_{56}O_{21}$. This is also found in many other ericaceous plants. It is glucosidal in nature and yields on decomposition, besides glucose, a volatile oil, *ericonol*. Another crystallizable principle has been discovered by Trommsdorf, who calls it *ursone*, $C_{30}H_{48}O_3$. It appears to be of a resinous character, although it can be obtained in silky needles, being tasteless and inodorous, insoluble in water, difficultly soluble in alcohol and ether, fusible, at a higher temperature volatilizable, and inflammable in the air. It is obtained by treating uva ursi with a very small quantity of ether by percolation, allowing the ether to evaporate, washing the crystalline extract with ether, and recrystallizing from alcohol. (*A. J. P.*, xxvii, 334.)

A. G. Perkin has obtained from the leaves of uva ursi a yellow coloring principle of the composition $C_{15}H_{10}O_7$, crystallizing in glistening yellow needles. On fusion with alkali, phloroglucinol and protocatechuic acid were formed. Though resembling quercetin in these points, it forms deep green solutions with diluted potassium hydroxide. (*A. J. P.*, 1898, 584.)

Uses.—Uva ursi is used to-day almost exclusively in the treatment of catarrhs of the urinary tract, especially *acute cystitis*. Although by some it is believed to exercise an astringent and alterative influence on these membranes, it is probable that its action is simply that of a mild antiseptic. Lewin (*V. A. P. A.*, 1883, xcii, p. 517) attributes its virtues to the arbutin which is decomposed in the system liberating hydroquinone. Bass, however (*Z. E. P. T.*, 1912, x, p. 120), is doubtful whether enough hydroquinone can appear in the urine to exercise any antiseptic effect. But whether or not its virtue is due to arbutin or some other principle, the clinical evidence is strong that uva ursi is a useful drug in these conditions. Formerly it was also employed in *gravel, nephritis, urethritis,* and *menorrhagia,* but has been largely abandoned. Because of the formation of hydroquinone in the body the urine often acquires a greenish color from the use of uva ursi.

Arbutin has been employed in medicine not only for its antiseptic effect but also as a diuretic in doses of from one to three grains (0.065–0.2 Gm.).

Dose, powdered uva ursi, from twenty grains to a drachm (1.3–3.9 Gm.), to be repeated three or four times a day; but the fluidextract is always preferred.

VALERIANA. U. S. (Br.)

VALERIAN Valer.

(vą-lē-rī-ā′ną)

"The dried rhizome and roots of *Valeriana officinalis* Linné (Fam. *Valerianaceæ*)." *U. S.* "Valerian Rhizome is the dried rhizome and roots of Valeriana officinalis, *Linn.* Collected in the autumn." *Br.*

Valerianæ Rhizoma, *Br.;* Valerian Root; Radix Valerianæ Minoris, R. Valerianæ Sylvestris, R. Valerianæ Montanæ; Common, Garden, Cat's or Great Wild Valerian, All-heal, Summer Heliotrope, Herb Bennet, Vandal Root; Valériane officinale, *Fr. Cod.;* Racine de Valériane, Valériane, *Fr.;* Radix Valerianae, *P. G.;* Baldrian, Wilde Baldrianwurzel, Baldrianwurzel, *G.;* Valeriana, *It.;* Valeriana (Rizoma de), *Sp.*

For *Valerianæ Indicæ Rhizoma,* see p. 1192.

Official or *great wild valerian* (*Valeriana officinalis*) is a large, handsome, herbaceous plant, with a perennial rhizome, and an erect, round, channelled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stems are attached by short, broad sheaths; the radical leaves are larger and long petiolate. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-colored, agreeably odorous, and disposed in terminal corymbs interspersed with pear-shaped bracts. The number of the stamens is three. The fruit is a capsule containing one oblong-ovate, compressed seed. The plant is a native of Europe, where it grows either in damp woods and meadows or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (*sylvestris* L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves.

The valerian plant is cultivated to some extent in New England and New York, and in Europe, in England and Holland. In this country it will grow in light, well-prepared, and well-drained soil, and is propagated by dividing the roots in the fall and setting these portions

in rows about two feet apart. (*D. C.*, lvi, p. 134.) In Europe it appears to be grown in a clayey soil. (*Pac. Pharm.*, vii, p. 297.) Mitlacher reports on the results of his experiments on the cultivation of valerian. (*Zeit. Oest. Apoth. Ver.*, l, p. 459.)

Valeriana mexicana DC.—According to the *Nueva Farmacopea Mexicana*, the roots of this plant contain a large percentage of valeric acid, which they yield readily and economically. In Mexican commerce they are said to occur in slices or fleshy disks about four centimeters or more in diameter, or in voluminous tubercles. Externally the color is grayish-yellow, internally yellow; the odor is strong and disagreeable, the taste bitter. R. McLaughlin (*A. J. P.*, 1893, 329) found 3.3 per cent. of oil in the Mexican valerian root. (See also *Schim. Rep.*, April, 1897.)

Japanese Valerian. Kesso Root.—This, formerly believed to be the product of *Patrinia scabiosæfolia* Link, is now thought to be obtained from a variety of *V. officinalis*. It yields a volatile oil. (*P. J.*, xx, 837, xxi, 1069.) The rhizome sometimes known as *Valerianæ Radix Majoris* is obtained from *V. Phu* L., of Southern Europe, and Western Asia. It is from 4 to 6 inches long, ½ inch in thickness, brown, annulated with numerous yellowish roots, and a feeble, valerian-like odor and taste.

Properties.—The root should be collected in spring, before the stem begins to shoot, or in the autumn, when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous, long, slender, brittle, cylindrical, thick-barked rootlets, issuing from a tuberculated rhizome. It is officially described as: "Rhizome upright, from 2 to 4 cm. in length, and from 1 to 2 cm. in diameter, usually cut longitudinally into 2 to 4 pieces; externally yellowish-brown or dark brown, upper portion with stem-bases and frequently with a short horizontal branch or stolon, and from the outer surface arise numerous, slender, brittle roots; fracture of rhizome short and horny, internally light brown, with a thick bark and narrow central cylinder; odor pronounced, of valeric acid, becoming stronger upon aging; taste sweetish, camphoraceous and somewhat bitter. Under the microscope, transverse sections of the root of Valerian show a single epidermal layer of papillose cells, some being modified to root hairs; a hypodermal layer containing some secretion cells with suberized walls, and in which are usually numerous small, oily globules and occasionally small prismatic crystals; cortical parenchyma, the cells filled with starch, some of the cells near the hypodermis containing a few oil globules; an endodermis of thin-walled cells enclosing a central cylinder with usually 3 to 5 fibro-vascular bundles; tracheæ with simple and bordered pores. Older roots show a large pith of starch-bearing parenchyma, a secondary thickening in the fibro-vascular bundles and a periderm of a few layers of cells. Sections of the rhizome show a thin periderm, a cortical parenchyma with scattered fibro-vascular bundles, a layer of altered cells of the endodermis, numerous, more or less twisted, collateral fibro-vascular bundles and a large pith. The powder is light brown to grayish-brown; under the microscope it exhibits numerous starch grains, from 0.003 to 0.02 mm. in diameter, spherical, plano-convex, polygonal, 2- to 4-compound and each usually with a central cleft; tracheal fragments, the walls having simple and bordered pores or scalariform and reticulate thickenings, accompanied by narrow sclerenchymatous fibers, the walls being thin, porous, and strongly lignified; occasional fragments of epidermis with root hairs, and fragments of cork. Valerian yields not more than 20 per cent. of ash." *U. S.*

"Rhizome short, erect, entire or sliced, dark yellowish-brown externally, whitish internally. Roots numerous, about seven to ten centimetres long, of the same color as the rhizome, slender, brittle. Strong, characteristic, disagreeable odor; taste unpleasant, camphoraceous, slightly bitter. Ash not more than 10 per cent." *Br.*

The roots of *Valeriana Phu* L., and *V. dioica* L., are said to be sometimes mingled with those of the official plant. According to Ebermayer, in Germany various ranunculaceous roots are a dangerous adulterant of valerian; they may be readily detected by their want of the peculiar odor of the official root. According to M. O. Raveil, the valerian in the markets of Paris is largely adulterated with the roots of *scabious* (*Scabiosa succisa* L., and *S. arvensis* L.). They are shorter than the genuine root, with larger radicles, less rough, little or not at all striated, very brittle, with a white amylaceous fracture. The roots are inodorous in themselves, but are very apt to acquire odor from contact with the valerian. (*J. P. C.*, xxvi, 209.)

The odor in the fresh root is pleasantly aromatic, but in the dried is stronger and less agreeable. Cats are strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic.

Trommsdorff found it to consist of 1.2 parts of volatile oil, 12.5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions, 18.75 of gum, 6.25 of a soft odorous resin, and 63 of lignin. Runge found in it a peculiar fixed acid, which produced with bases white salts, becoming green on exposure to the air. (*Chem. Gaz.*, No. 170, p. 452.) Of these constituents the most important is the *volatile oil*. It is of a pale greenish color, of the sp. gr. 0.934, with the pungent odor of valerian, and an aromatic taste. It becomes yellow and viscid by exposure. Bruylants (*Ber. d. Chem. Ges.*, 1878, p. 449) has obtained from oil of valerian, (1) a hydrocarbon or terpene, $C_{10}H_{18}$, boiling at 157° C. (314.6° F.); (2) a liquid compound, $C_{10}H_{18}O$, which by means of chromic acid affords common camphor, and formic, acetic, and valeric acids, which are met with in old valerian root, owing no doubt to the slow oxidation of the compound $C_{10}H_{18}O$; (3) a crystalline compound of the same composition, which in the root is probably combined with the three organic

acids mentioned, forming corresponding esters with them: (4) at from 285° to 290° C. (545°–554° F.), a greenish, syrupy oil, which when rectified is colorless, and seems to have the composition of a *borneol oxide*, $(C_{10}H_{17})_2O$. Schimmel & Co. (*Schim. Rep.*, April, 1897) summarize the most recent researches upon valerian oil from different sources. In the oil from Dutch and Thuringian roots, the amount varying from 0.5 to 1 per cent., they find pinene, camphene, borneol, bornyl formate, bornyl acetate, and *bornyl isovalerate*, together with a sesquiterpene and an alcohol, $C_{10}H_{20}O_2$. In the oil from Japanese roots (amounting to from 6 to 6.5 per cent.) (*Kesso oil*), they find pinene, camphene, dipentene, terpineol, borneol, bornyl acetate, bornyl isovalerate, and *kessyl acetate*. Trommsdorff ascertained the existence in the oil of *valeric acid*.

This acid is a colorless volatile liquid, of an oleaginous consistence, having an odor analogous to that of valerian, and a very strong, sour, disagreeable taste. It is soluble in thirty parts of water, and in all proportions in ether and alcohol. It combines with salifiable bases, forming soluble salts, which retain, in a diminished degree, the odor of the acid. (*J. P. C.*, xx, 316.) The acid does not pre-exist in the oil, but is produced by the decomposition of its borneol ester. Valeric acid is obtained by distilling the impure oil with magnesium carbonate, decomposing by sulphuric acid the magnesium valerate which remains, and again distilling. The following process by T. and H. Smith, of Edinburgh, avoids the inconvenience of distilling so bulky a root as valerian, while it answers the same purpose as that of Rabourdin. Boil the root for three or four hours with rather more than its bulk of water in which an ounce of sodium carbonate is dissolved for every pound of the root, replacing the water as it evaporates. Express strongly, and boil the residuum twice with the same quantity of water, expressing each time as before. Mix the liquids, add two fluidrachms of strong sulphuric acid for every pound of the root, and distil until three-fourths of the liquid have passed over. Neutralize this with sodium carbonate, concentrate the liquid, decompose the sodium valerate contained in it by sulphuric acid, and collect the valeric acid set free, by a separator, funnel, or by distillation. (*A. J. P.*, xvii, 253.) Lefort obtains the acid by the rapid oxidation of the volatile oil. He distilled 100 parts of the root with 500 of water, 10 of sulphuric acid, and 6 of potassium dichromate, and in this way procured a larger proportion of acid than by any other process. (*J. P. C.*, 3e sér., x, 194.)

Uses.—Valerian is used as a sedative to the higher nerve centers in conditions of *nervous unrest, hysteria, hypochondriasis, neuralgic pains*, and the like. The virtues of the plant seem to depend chiefly on the esters of valeryl which are contained in the volatile oil. According to Chevalier (*Nouv. Rem.*, 1912, xxix, p. 169), the volatile oil of valerian is a depressant to the whole central nervous system, including both the motor and psychical centers of the brain and the motor cells of the spinal cord. The esters contained in this drug are unstable bodies and in the process of drying largely oxidized with the formation of valeric acid. As the latter is practically without physiological action much of the virtue of the plant is lost during the drying process. Probably for this reason preparations of this drug are very uncertain in their activity and valerian has largely fallen into disrepute. Chevalier has introduced the juice of the fresh root which he asserts is a valuable remedy not only for the conditions mentioned above, but even as a narcotic in *insomnia* and an anticonvulsant in *epilepsy*. The dose of this juice, which has been introduced under the name of *energetene of valerian*, is one to three coffeespoonsful. It appears also to have some slight influence upon the circulation, slowing the heart and increasing its force, and causing a rise in blood pressure, and has been used in the treatment of *cardiac palpitations*.

Dose, twenty to forty grains (1.3–2.6 Gm.). The dose of the oil of valerian, which is occasionally employed, is four to five minims (0.25–0.3 mil).

VALERIANÆ INDICÆ RHIZOMA. Br.

INDIAN VALERIAN RHIZOME

(vạ-lē-rĭ-ā'næ ĭn'dĭ-cæ rhī-zō'mạ)

"Indian Valerian Rhizome is the dried rhizome and roots of Valeriana Wallichii, *DC.*" *Br.*

Valeriana Wallichii is a perennial herb growing in the temperate Himalayas and in the Khasia Mountains. The rhizome is more largely used as a perfume than in medicine. It is used in preparations for the hair and the dried rhizome is used as an incense. It is officially described as follows: "Rhizome curved, about five centimetres long, from five to ten millimetres thick, dull brown, with raised transverse leaf-scars, numerous prominent root-scars and a few thick roots; the crown bearing the remains of petioles. Fracture short. In transverse section, dark with a large pith and diffuse ring of small wood-bundles. Strong, characteristic, disagreeable odor; taste unpleasant, camphoraceous." *Br.*

According to Lindenberg (*Ph. Z. R.*, 1886), Indian valerian is practically identical in its composition with the European drug, but contains a slightly larger amount of volatile oil. It may be employed in the same class of cases as valerian.

VANILLINUM. U. S.

VANILLIN Vanillin.

(vạ-nĭl-lĭ'nŭm)

"Methylprotocatechuic aldehyde [$C_8H_8O_3$ or $C_6H_3.OH.OCH_3.COH$ 4 : 3 : 1 = 152.06] occur-

ring naturally in vanilla, or prepared synthetically. Preserve it in well-closed containers, protected from light." *U. S.*

Vanilline, *Fr. Cod.*; Vanillin, Vanillekampher, Protocatechualdehydmethylaether, *G.*

Preparation.—*Vanillin* was first obtained from vanilla by Gobley, who, by exhausting vanilla with 85 per cent. alcohol, evaporating the resulting tincture to an extract, softening this with water, and agitating in a flask with ether so long as it gave color to that fluid, then evaporating the ethereal liquid and treating the residue with boiling water, obtained on the evaporation of the water a crop of crystals having the odor of vanilla. Purified by treatment with animal charcoal and recrystallization, the principle appeared in the form of colorless, long, four-sided needles terminated by two faces. It has a strong odor of vanilla, with a hot, biting taste, and is frequently seen in acicular crystals upon the external surface of the bean. This compound, for which Gobley proposed the name *vanillin*, is now recognized as the methyl-ether of protocatechuic aldehyde, $C_6H_3\begin{cases}OCH_3\\OH\\COH,\end{cases}$ or $C_8H_8O_3$, and is known to occur somewhat diffused in the vegetable kingdom, being found in the sugar beet and in the wood-tissue of many plants. It forms crystalline needles fusing at 80° to 81° C. (176°–177.8° F.), difficultly soluble in cold water, readily soluble in hot water, easily soluble in alcohol and ether, chloroform, and carbon disulphide. It oxidizes slowly in damp air to *vanillic acid*, $C_8H_8O_4$; when heated with diluted hydrochloric acid to 200° C. (392° F.), it breaks up into methyl chloride and protocatechuic acid. Tiemann and Haarmann (*Ber. d. Chem. Ges.*, 1874), who first ascertained the true character of vanillin, also found that it could be made synthetically from *coniferin*, a glucoside contained in the cambium layer of the pine. This coniferin, $C_{16}H_{22}O_8 + 2H_2O$, or the compound $C_{10}H_{12}O_3$, which with glucose results from its decomposition, is oxidized by sulphuric acid and potassium dichromate with the production of vanillin. Artificial vanillin was made in this way from coniferin under Tiemann and Haarmann's patents, and was made by Reimer and Tiemann from guaiacol by heating it with sodium hydroxide and chloroform, but it is now made from *eugenol*, $C_6H_3\begin{cases}OH\\OCH_3\\CH_2.CH:CH_2\end{cases}$. This on heating with alcoholic solution of potassium hydroxide is changed into *isoeugenol*, $C_6H_3\begin{cases}OH\\OCH_3\\CH:CH.CH_3\end{cases}$, and this is then oxidized, when *vanillin*, $C_6H_3\begin{cases}OH\\OCH_3\\CHO\end{cases}$ is formed. A larger yield is obtained if the isoeugenol is first acetylated, as the acetisoeugenol is more stable under the influence of oxidizing agents. The product acetvanillin is readily decomposed, with the liberation of the vanillin. The oxidation is effected by a variety of oxidizing agents. Sodium peroxide has been used with success, or more recently the isoeugenol sodium has been oxidized at the positive pole of an electrolytic cell, using an alkaline hydroxide as the cathode liquid. Oil of cloves is therefore used as a basis for the manufacture of artificial vanillin.

Properties.—It is officially described as "in fine, white, or only very slightly yellowish, crystalline needles, having the odor and taste of vanilla. One Gm. of Vanillin dissolves in 100 mils of water at 25° C. (77° F.); also in 16 mils of water at 80° C. (176° F.); freely soluble in alcohol, glycerin, chloroform, or ether. Its aqueous solution is acid to litmus and is optically inactive. It melts between 80° and 82° C. (176° and 179.6° F.). It is easily dissolved by aqueous solutions of the alkali hydroxides, and from the combinations thus formed it is precipitated at once by the addition of acids. An aqueous solution of Vanillin gives a blue color with ferric chloride T.S.; if the mixture is boiled, the blue color changes to brown, and on cooling a white, or nearly white, precipitate of dihydrodivanillin separates. Vanillin is extracted completely from its solution in ether by shaking with a saturated, aqueous solution of sodium bisulphite, from which it is precipitated by the addition of sulphuric acid. A cold aqueous solution of Vanillin gives, on the addition of lead acetate T.S., a white precipitate of a lead compound of vanillin, soluble in hot water. Incinerate about 2 Gm. of Vanillin; not more than 0.05 per cent. of ash remains. Warm about 0.1 Gm. of Vanillin with a concentrated alcoholic solution of sodium hydroxide, add a drop of chloroform and again warm; the odor of phenylisocyanide is not perceptible (*acetanilid*)." *U. S.*

A new qualitative test and colorimetric method for the quantitative estimation of vanillin has been described by Clarence Estes (*J. I. and E. C.*, 1917, p. 142) which depends upon the effect of the addition of solution of acid nitrate of mercury under certain conditions. A violet to violet-red color is produced, which is unlike that produced by any organic compound likely to be present as an accidental or interfering substance. The results of the application of the author's method directly to flavoring extracts of known composition agreed closely with the gravimetric figures.

Uses.—According to Grasset, vanillin produces in frogs spinal convulsions followed by paralysis due to a direct action upon both the spinal cord and motor nerves. It has been suggested as a stomachic and excito-motor given in doses of three-fourths of a grain (0.048 Gm.).

(*A. Pharm.*, Aug., 1896.) Neither it nor vanilla, however, are used for other than flavoring purposes. The fact that while the vanilla beans have steadily risen in price for a number of years that of the artificial vanillin has enormously fallen, indicates that as a flavoring agent vanillin is not equal to the natural product. It is said that articles flavored with it leave a peculiar, disagreeable after-taste and retain their flavor only a very short time.

VERATRINA. U. S.

VERATRINE Veratrin. [Veratria]

(vĕr-ą-trī'ną)

"A mixture of alkaloids obtained from the seed of *Asagræa officinalis* (Chamisso and Schlechtendal) Lindley (Fam. *Liliaceæ*). Preserve it in well-closed containers, protected from light." *U. S.*

Vératrine, *Fr. Cod.;* Veratrinum, *P. G.;* Veratrin, *G.;* Veratrina, *It., Sp.*

No process is given in the U. S. P. IX for preparing veratrine and the Br. Pharm., 1914, deleted it. A process will be found in the *U. S. D.*, 19th edition, pages 1327 and 1328.

In the U. S. process of 1870 the first step is to obtain a tincture of cevadilla, which is evaporated to the consistence of an extract. This contains the veratrine combined with a vegetable acid, probably gallic, as it exists in the seeds. From the extract the alkaloid is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the natural acid. The magnesia combines with the acids and throws down the veratrine, which is then taken up by alcohol and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the British process, the tincture was concentrated until it began to let fall a precipitate, and was then poured into water, which throws down the resin and oil with a portion of the coloring matter and retains the salt of veratrine. This is then decomposed by ammonia, and the precipitated veratrine is slightly washed with cold water to free it from adhering impurities. If much water be employed in the washing, a considerable portion of the veratrine will be lost, in consequence of impure veratrine being in some degree soluble in water. The remaining steps of the British process consist in the purification of the veratrine by forming a hydrochloride in solution, decolorizing this by animal charcoal and again precipitating by ammonia.

The U. S. process of 1870 is essentially that of Couërbe. The veratrine obtained by it, though not pure, is sufficiently so for medicinal use. A drachm of it, in this state, may be procured from a pound of cevadilla. Meissner, in 1819, applied the term *sabadilline* to an alkaloid extracted by him. Pelletier and Caventou had probably produced the same preparation when they announced the discovery of veratrine in the same year. This substance is the veratrine described as prepared by Couërbe's process. Couërbe, in 1834, announced the discovery of an additional alkaloid, to which he gave Meissner's old name of sabadilline, and Weigelin, in 1871, announced the discovery of a third alkaloid, which he called *sabatrine*. G. Merck, in 1855, obtained veratrine in a crystallized state by solution and separation from strong alcohol.

Wright and Luff (*J. Chem. S.*, 33, p. 338) have brought order from this confusion by a careful study of the whole subject. They found three alkaloids in sabadilla seeds: *cevadine*, $C_{32}H_{49}O_9N$ (the alkaloid hitherto known as the veratrine of Merck); *veratrine*, $C_{37}H_{53}O_{11}N$; and *cevadilline*, $C_{34}H_{53}O_8N$. Of these, the cevadine (formerly veratrine) forms, when crystallized from alcohol, needles or compact crystals which fuse at 205° C. (401° F.), effloresce rapidly in the air, and become opaque, are insoluble in water, easily soluble in alcohol and ether, and dissolve in warm concentrated hydrochloric acid with a dark violet color, which on boiling becomes intensely red. When heated with alcoholic potassium hydroxide they are decomposed into *methyl-crotonic* (*tiglinic*) *acid* and *cevine*, $C_{27}H_{43}O_8N$. The veratrine of Wright and Luff is obtained from the mother liquor of the cevadine by extraction with ether. It forms an uncrystallizable resinous mass, fusing at 180° C. (356° F.), but yields crystallized salts. Boiled with sodium hydroxide it is decomposed into *dimethyl-protocatechuic* (*veratric*) *acid* and *verine*, $C_{28}H_{45}O_8N$. Cevadilline remains after the extraction of the veratrine, insoluble in ether. It is also uncrystallizable, nearly insoluble in ether and in boiling benzene, but easily soluble in fusel oil.

Flückiger recognized only two of these alkaloids, and made them both of the composition $C_{32}H_{49}O_9N$. The first, which he called *cevadine*, he stated is decomposed by boiling with barium hydroxide when in alcoholic solution, and yielded products as follows:

$$C_{32}H_{49}O_9N + 2H_2O = C_5H_8O_2 + C_{27}H_{45}O_9N$$

The first of these products is *methyl-crotonic acid*, and the second is *cevine*. The other alkaloid he called *veratridine*, and gave its decomposition as follows:

$$2C_{32}H_{49}O_9N + 4H_2O = C_9H_{10}O_4 + C_{55}H_{92}O_{16}N_2 + 2H_2O$$

The first of these products is *dimethyl-protocatechuic acid*, and the second he called *veratroïn*. (Flückiger, *Pharm. Chem.*, 1888, ii, p. 532.) Merck still terms the cevadine of Wright and Luff veratrine, and prepares it in white crystals of the formula $C_{32}H_{49}O_9N$, fusing at 202° C. (395.6° F.). Frankforter (*A. J. P.*, 1897, 372) confirmed this formula, $C_{32}H_{49}O_9N.H_2O$, but gave to the purified veratrine the

melting point from 146° to 148° C. (294.8°–298.4° F.).

Two acids have also been found in sabadilla—the *sabadillic* or *cevadic acid* of Pelletier and Caventou, forming needle-like crystals fusing at 20° C. (68° F.), and the *veratric acid* of Merck, which Koerner showed to be dimethylprotocatechuic acid.

Properties.—Veratrine is officially described as "a white, or grayish-white, amorphous powder, odorless, but causing intense irritation and sneezing when even a minute quantity reaches the nasal mucous membrane. *Great caution must be used in tasting it.* It is slightly hygroscopic. One Gm. of Veratrine dissolves in 1760 mils of water, 2.8 mils of alcohol, 0.7 mil of chloroform, and in 4.2 mils of ether at 25° C. (77° F.); also in 1345 mils of water at 80° C. (176° F.); insoluble in petroleum benzin. Its alcoholic solution is alkaline to moistened litmus paper. Triturate about 0.05 Gm. of Veratrine with 2 mils of sulphuric acid in a glass mortar; the yellow or orange-red solution exhibits by reflected light a greenish fluorescence, which becomes more intense upon the addition of an equal volume of sulphuric acid. Upon standing, the solution gradually assumes a deep red color. Sulphuric acid, when heated with Veratrine, gives a cherry-red color. Sulphuric acid added to a mixture of one part of Veratrine and six parts of sugar produces a green color which changes to blue, and finally the mixture becomes colorless. No weighable ash remains on incinerating 0.1 Gm. of Veratrine. An alcoholic solution of Veratrine (1 in 20) remains clear after the addition of platinic chloride T.S. (*various foreign alkaloids*)." *U. S.*

Uses.—Probably because of its unfortunate name it has been assumed by some that veratrine represents the therapeutic virtues of veratrum. Its physiological action, however, differs greatly from that of veratrum, and if it possess any therapeutic usefulness it is certainly not for the conditions for which veratrum is employed.

Veratrine is an intense local irritant and somewhat locally anesthetic. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling. Sometimes an evanescent blush is produced and still more rarely an eruption upon the skin, but generally no decided signs of inflammation are evinced. When taken into the mouth it produces an almost insupportable sense of acrimony, and snuffed up the nostril it produces violent sneezing, and when taken into the stomach in large doses it causes violent vomiting, serous purging with intense burning in the mouth and throat and general muscular weakness. It is a powerful muscle poisoning and if given in sufficient dose in the lower animals it causes an extraordinary prolongation of the contraction of the striated muscles; the time required for relaxation of voluntary muscles may be 20 or 30 times as long as normal. A similar influence is exerted upon the ventricular muscles, at least in the frog, but the slowing of the heart rate seen in warm blooded animals seems to be due chiefly to stimulation of the cardio-inhibitory center. Death in mammals is generally due to depression of the respiration.

The only justifiable therapeutic use of veratrine is as an anodyne counter-irritant in *neuralgias* and various forms of *arthritis*. Even for this purpose it has no advantages sufficient to offset the dangers of systemic poison which might follow from its absorption.

Dose, one-thirtieth of a grain (0.002 Gm.).

VERATRUM VIRIDE. U. S.

VERATRUM VIRIDE Verat. Vir. [Green Hellebore, American Hellebore]

(vẹ-rā-trŭm vĭ'rĭ-dē)

"The dried rhizome and roots of *Veratrum viride* Aiton (Fam. *Liliaceæ*), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." *U. S.*

Big or False Hellebore, Swamp Hellebore, Indian Poke, Itch-weed, Tickle-weed, Bugbane; Vératre vert, *Fr.;* Grüner Germer, *G.;* Vedegambre verdo, *Sp.*

In the several revisions of the U. S. Pharmacopœia, *veratrum* has been handled in a vacillating manner. In 1880 and 1890 the drug was restricted to that obtained from *V. viride*. In 1900 both *V. viride* and *V. album* were recognized, this being done for reason of the large importations of Veratrum (*V. album*) and there being no practical method of distinguishing between these two drugs. The U. S. Pharmacopœia IX has wisely restricted the definition, in the interest of uniform medicine, to *V. viride*. This, however, may offer some practical commercial difficulties as it is not always easy to differentiate its substitution by *V. album,* and certainly it is almost impossible to detect an admixture with the European drug.

That the two species are very closely allied, and the two rhizomes histologically, chemically, and toxicologically very similar is indisputable, but similiarity is not identity. The European plant seems to be more actively poisonous than is the American, and has been said by some chemists to contain a larger proportion of the alkaloids. It usually also has a distinctly greater action upon the intestinal tract and it is probable that the proportionate amounts of the alkaloids differ in the two species. The conclusions reached in an elaborate physiological research made by H. C. Wood and H. C. Wood, Jr., for the Committee of Revision of the U. S. VIII was that the drugs can scarcely be distinguished physiologically, but that the European plant is more likely to disturb the intestines and that in the absence of any cogent reason for recognizing *V. album,* veratrum viride should alone be retained.

The American hellebore, *Veratrum viride*, known also by the names of *Indian poke, poke root,* and *swamp hellebore,* has a perennial, thick, fleshy rhizome, the upper portion of which is tunicated, the lower solid, and beset with numerous whitish roots. The stem is annual, cy-

lindrical, striated, pubescent, and solid, from three to six feet in height, furnished with bright green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent, and embrace the stem at their base, thus affording it a sheath for a considerable portion of their length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong-lanceolate. The panicle consists of numerous flowers, distributed in racemes with downy peduncles. Each flower is accompanied by a downy, pointed bract, much longer than its pedicel. The perianth consists of six oval acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments and roundish two-lobed anthers. The ovary is ovoid, tri-carpellary; styles three and persistent. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those below fruitful. The fruit is a three-lobed capsule, three-celled, and containing flat imbricated seeds. This indigenous species of veratrum inhabits swamps, wet meadows, and the banks of mountain streamlets. It is more abundant northward, but reaches as far south as Georgia. From May to July is the season for flowering. It is doubtful whether the rhizome should be collected in autumn or just before flowering. It should be thoroughly dried and carefully preserved, as otherwise it deteriorates.

Veratrum album L. (*V. viride* Roehl., but not *V. viride* Aiton.).—The specific difference between this plant, which is a native of Europe and Northern Asia, and *V. viride* of North America has been questioned by various botanists, but it is now generally acknowledged that the two species are distinct. (See *Index Kewensis;* also Engler and Prantl.) *V. album* resembles closely the American species, but is distinguished by its yellowish-white flowers. The rhizome of *V. nigrum* of Central Europe is said to be sometimes substituted for that of *V. album,* but is much smaller. According to the Pharmacographia, that of the Mexican species, *V. frigidum* Schl., exactly resembles that of *V. album.*

Properties.—As found in commerce, veratrum is usually in small pieces or fragments, but sometimes it comes whole or sliced, so that its characteristic form may be observed. In this condition it is seen to consist of a rhizome one to three inches in length by somewhat less than an inch in thickness where broadest, tapering to a very obtuse or truncated extremity, simple or divided, compact but light, of a dark-brown color externally, and either closely invested with numerous yellow rootlets often several inches long, or exhibiting marks on the surface whence they have been removed. When sliced, the cut surface is of a dingy-white color. The rootlets are from three to six inches long, about as thick as a large knitting needle, or somewhat thicker, obviously much shrunk in drying, and marked by numerous closely set indentations, which give them a characteristic appearance. Not unfrequently portions of the dried stem or leafstalks remain attached to the rhizome, which should always be rejected, as they were ascertained by Procter to be inert. (*A. J. P.,* 1864, p. 99.)

Veratrum Viride is officially described as follows: "Rhizome upright, obconical, usually cut longitudinally into 2 to 4 pieces, from 2 to 7 cm. in length and from 1.5 to 3 cm. in diameter, externally light brown to dark brown or brownish-black, frequently bearing at the summit numerous, closely arranged, thin leaf-bases, otherwise rough and wrinkled, somewhat annulate from scars of bud-scales and bearing in the outer portion numerous roots, the lower part more or less decayed; fracture hard and horny; internally yellowish or grayish-white, marked with numerous, irregular fibro-vascular bundles; inodorous but sternutatory; taste bitter and acrid. Roots nearly cylindrical, from 3 to 8 cm. in length and from 1 to 3 mm. in diameter; externally light brown to yellowish-brown, deeply transversely wrinkled; fracture short, bark whitish, very thick, enclosing a porous central cylinder. The powder is grayish-brown to dark brown, strongly sternutatory; under the microscope it exhibits numerous starch grains from 0.003 to 0.02 mm. in diameter, spherical or ellipsoidal, single or 2- to 3-compound, the individual grains being often swollen or otherwise more or less altered; calcium oxalate in raphides, from 0.015 to 0.15 mm. in length; fragments with tracheæ, the walls being more or less strongly lignified and marked with scalariform or reticulate thickenings, frequently containing a lemon-yellow substance and associated with narrow, slightly lignified, porous, sclerenchymatous fibers; reddish-brown or brownish-black cork fragments occasional." *U. S.*

It has been asserted that the color of *V. album* is much lighter than that of *V. viride,* but this certainly is practically incorrect, however it may apply to carefully preserved specimens. Very commonly the roots have been removed from commercial *V. album,* while in America they are generally allowed to remain on the rhizomes. According to R. H. Denniston, no microscopic differences can be detected in the rhizomes, but in the roots distinction is possible owing to the fact that directly beneath the epidermis in the *V. viride* the collenchyma region consists of but two or three rows of large, irregular and distorted cells, while in *V. album* this region is generally made up of seven to eight rows of rounded, thicker-walled and smaller cells, which are not in the least distorted. Any such test is, of course, inapplicable to the drug in powder. In the color test proposed by R. H. Denniston, sulphuric acid is added to the powder; with *V. album* a brick-red color, with *V. viride* an orange-red color, will be produced. Of course the test is of little value in determining the character of a powder, as it does not possess sufficient differentiation.

The pharmacognosy of *V. viride* has been well illustrated by Bastin (*A. J. P.,* 1895, p. 196). The structure of *V. album* has been presented by

Meyer (*Arch. d. Pharm.*, 1882, p. 81; and in "*Wissenschaftliche Drogenkunde*," vol. 2, p. 46). Rosenthaler has submitted veratrum to pyroanalysis and has obtained a sublimate which is in part crystalline and gives a yellowish-red color with sulphuric acid. (*Apoth. Zeit.*, xxviii, p. 991.)

Pelletier and Caventou, in 1819, found in the rhizome of *Veratrum album* a substance which they regarded as identical with the veratrine just announced by Meissner as contained in sabadilla seeds. Simon (*Ann. Ch. Ph.*, 24, p. 214), in 1837, found the alkaloid *jervine* also in *Veratrum album.* Bullock (*A. J. P.*, 1865, p. 321) found that while *Veratrum viride* contained at least two characteristic alkaloids, neither of these was veratrine. The alkaloids noted by Bullock were named in a former edition of this work *viridine* and *veratroidine.* Peugnet (*N. Y. M. R.*, 1872, p. 120), in 1872, showed the identity of the first of these with jervine, and this was confirmed by Mitchell (*A. J. P.*, 1874), who also made out a distinct alkaloid in *Veratrum album,* to which he applied the name of *veratralbine.* The veratroidine discovered by Bullock in *Veratrum viride* in 1865 was also found in *Veratrum album* by Tobien in 1877. In a paper published in the *A. J. P.*, April, 1876, Bullock expressed his doubt as to the existence of veratroidine as a distinct alkaloid, considering that it might have been only jervine admixed with resin. Here the matter rested until the elaborate researches of Wright and Luff (*J. Chem. S.*, xxxv, 405, 421) who found in *Veratrum album: jervine,* $C_{26}H_{43}O_2N + 2H_2O$, *rubijervine,* $C_{26}H_{43}O_2N$, *pseudojervine,* $C_{29}H_{43}O_7N$, *veratralbine,* $C_{28}H_{43}O_5N$ (?), and also traces of an alkaloid having sternutatory power (possibly *cevadine*). In *Veratrum viride* they found jervine, pseudojervine, cevadine, very little rubijervine, and traces of veratrine and veratralbine. Of these, rubijervine probably agrees with Bullock's veratroidine, although as prepared by Bullock in his earlier experiments it was undoubtedly mixed with resin, as the fusing point given 132.2° to 135° C. (270°–275° F.) is much lower than that given by Wright and Luff for their pure crystals, which fused at 236° C. (456.8° F.). Pseudojervine forms crystals very similar to those of jervine, but it fuses at 299° C. (570.2° F.), instead of 231° to 237° C. (447.8°–458.6° F.). Pehkschen (*A. J. P.*, 1891) finds *jervine* in both the Veratrum species. Obtained by recrystallization from absolute alcohol it forms snow-white crystals of the formula $C_{14}H_{22}O_2N$ (determined by the analysis of the base and of its hydrochloride and sulphate). It melts at 237.7° C. (460° F.), and is slightly lævogyre. He finds *veratroidine* (rubijervine of Wright and Luff), and gives it the formula $C_{32}H_{53}O_9N$ (determined both by analysis and by molecular weight determination). It melts at 149.2° C. (300.6° F.), and is optically inactive. He obtained, thirdly, an alkaloid in rhombic crystals, which is probably a purer form of Wright and Luff's *pseudojervine.* Its formula is $C_{29}H_{49}O_{12}N$. It melts at 259.1° C. (498.4° F.), and is optically inactive. No color reactions could be obtained with this base, but if the slightest quantity of veratroidine or jervine is added, color reactions agreeing with Wright and Luff's pseudojervine are obtained. A very small quantity of a fourth alkaloid (Wright and Luff's veratralbine) was obtained, but not enough to allow of present investigation. Salzberger (*A. J. P.*, 1891) obtained the three bases *jervine, rubijervine,* and *pseudojervine,* and two new ones, *protoveratrine* and *protoveratridine,* from the rhizome of *Veratrum album;* the first of these two bases has the formula $C_{32}H_{51}O_{11}N$, and crystallizes in microscopic four-sided plates, which melt with charring at 245° to 250° C. (473°–482° F.). The base is exceedingly poisonous and violently sternutatory. It is insoluble in water, benzene, and petroleum benzin, slightly soluble in chloroform, boiling 96 per cent. alcohol, and ether. Dilute acids, with the exception of acetic acid, dissolve it. *Protoveratridine,* $C_{26}H_{45}O_8N$, occurs as colorless four-sided plates, which melt at 265° C. (509° F.). It is not poisonous, and does not cause sneezing. It is almost insoluble in the common solvents, but is soluble in dilute acids. Worthington pointed out the presence of gallic acid and sugar in *Veratrum viride.*

Uses.—The various alkaloids present in veratrum act upon the system in very different manners, and none of them appears to exercise exactly the same action as the whole drug. According to H. C. Wood (*Phila. Medical Times,* 1874, iv, p. 737), jervine is a depressant to the respiratory center, to the vasomotor center, and to the heart muscle, and also lowers reflex activity by an effect upon the spinal cord, and rubijervine is chiefly a stimulant to the cardio-inhibitory mechanism, but has a more depressant action upon the respiratory center. According to Eden (*A. E. P. P.*, 1892, xxix, p. 440), small doses of protoveratrine stimulate cardiac inhibition thereby causing a lowering of the blood pressure. In large doses there is a secondary paralysis of inhibition accompanied by rise in the pressure. In large quantities it also exercises a poisonous effect upon the voluntary muscles similar to that of veratrine. Rubijervine is present in such small proportions (according to Breideman, *J. P.*, 1906, lxxxiv, 0.053 per cent.) and is so feeble a substance that it is improbable that it plays any part in the physiological action of the drug. Jervine, although present in larger quantities (0.34 per cent.), according to H. C. Wood, Jr., is less poisonous than the drug itself. Protoveratrine, although present in small amounts (0.06 per cent., according to Breideman), is an extremely toxic substance and is the most important of the ingredients at present known. It appears to differ, however, in some of its properties from the whole drug.

When a moderate dose of veratrum is introduced into the system, the most marked change produced is reduction in the rate of the pulse accompanied with a fall in the arterial pressure. At the same time there may be some slow-

ing in the respiration. With proper doses the slowing of the pulse is extreme and we have seen, in the lower animals, even complete arrest of the heart at this stage of the poisoning. The slowing of the pulse does not occur if the pneumogastric nerves have been divided previous to the injection of the drug, and is at once abolished either by section of these nerves or by the administration of atropine. It must be regarded, therefore, as due to stimulation of the cardio-inhibitory center. The reduction in the arterial tension in the normal animal may, therefore, be attributed to the slowing of the pulse. The conclusions of H. C. Wood, Jr. (*U. P. M. B.*, March, 1908), that contrary to the older views, veratrum does not lower arterial tone, have been confirmed by the experiments of Pilcher and Sollmann (*J. P. Ex. T.*, 1915, vii, p. 295) on animals and the observations of Collins (*A. I. M.*, 1915, xvi, pp. 54–58) on man. After toxic doses of veratrum there is a late paralysis of the intra-cardiac terminals of the pneumogastric nerve and consequent increase in the pulse rate with at first a rise of the blood pressure followed by a fall. This toxic fall in the blood pressure appears to be due to a direct depressant action upon the heart muscle. There is, following the toxic dose, also marked reduction in the respiratory activity, death being due eventually to failure of this function.

Veratrum was introduced into medicine about a century ago by the group of physicians who called themselves "eclectics." By them it was attributed with mysterious "adenagic" virtues and used in all sorts of inflammatory diseases. Later under the belief that it dilated the blood vessels and hence would relieve various local congestions, regular practitioners employed it largely in the treatment of *pneumonia, peritonitis,* and other sthenic *fevers.* While it is still employed to some extent in this type of disorder, our knowledge of its physiological action indicates that its true field of usefulness is rather in chronic, than in acute, diseases. Thus it is a very valuable agent for the reduction of excessively *high blood pressure* in *arteriosclerosis, interstitial nephritis,* and other conditions of hypertension; in cases with feeble myocardia it should be used cautiously because the stimulation of the cardio-inhibitory mechanism predisposes to cardiac dilatation. For the same purpose it is often employed in threatened *apoplexy,* in *chronic endocarditis,* especially in those in which there is considerable degree of cardiac hypertrophy, and in the so-called *irritable heart* seen in soldiers and athletes. In *exophthalmic goitre* and various other forms of *tachycardia* it is frequently of great service to reduce the pulse rate and prevent the heart exhausting itself in excessive activity. In certain of these conditions its line of usefulness more or less parallels that of digitalis. It differs, however, sharply from that drug, in that while digitalis tends to increase the tone of the heart muscle, veratrum rather diminishes cardiac tone. Veratrum has also been used widely by obstetricians in the treatment of *puerperal eclampsia.* Whether its benefit in this condition is to be attributed to a depressant action upon the motor cord, as some believe, or whether it be due to a lowering of the blood pressure, is as yet uncertain. The dose of veratrum must be gauged by the effect it produces; in general it may be said that if it does not slow the pulse no benefit will be received by the patient. The drug should therefore be pushed until evidence of its action is seen in the reduction of the pulse rate. Ordinarily from one to three minims (0.06–0.2 mil) of the fluidextract may be given every two or three hours until it manifests its action. It should be remembered, however, that in some cases the cardio-inhibitory mechanism is refractory to the action of the drug and no dose will slow the pulse, and if given incautiously it may do great harm. Fortunately in most instances if given in too large dose it will manifest its toxic action by nausea before any more serious symptoms are produced.

Toxicology.—The symptoms of veratrum poisoning are vomiting accompanied with great nausea and much retching. There is profound prostration with muscular weakness, the skin bedewed with perspiration and pale in color, the pulse, in the milder cases, or in the early stage of the severe cases, is extremely slow and easily compressible, later, in the severe types of poisoning, it may become rapid and irregular. The respirations are often shallow and sometimes stertorous. Frequently there is much complaint of dizziness and in a few cases there has been dilatation of the pupil with disturbance of vision. Because of the promptness with which vomiting comes on even very large single doses of veratrum may be recovered from, thus Buckingham (*A. J. M. S.*, 1865) reports a case in which recovery followed a teaspoonful of the fluidextract. But when repeated large doses have been taken, the poisoning is much more dangerous.

In the treatment of veratrum poisoning if the patient be vomiting it is well to give a couple of glasses of water in order to thoroughly cleanse the stomach, at the same time twenty grains (1.3 Gm.) of tannic acid may be exhibited as an imperfect chemical antidote. If for any reason vomiting has not occurred it should be at once provoked or the stomach washed out by means of a stomach pump. The patient must be kept in a horizontal position and should not be allowed to sit up to vomit. After washing out the stomach in the manner described above, efforts should be made to stop the vomiting by the use of counter-irritation over the epigastrium and the cautious employment of morphine. But since when the drug proves fatal death is due to the respiratory arrest the latter should not be given in too large doses. If seen in the early stages when the pulse is slow, atropine is a remedy of great value antagonizing the effect of the veratrum upon the pneumogastric nerve and at the same time checking the excessive sweating and stimulating the respiratory center. Other active respiratory stimulants, such as hypodermic injections of ammonia and strych-

nine, may be employed, and if the bodily temperature is low it should be maintained by the external application of heat.

Dose, one to two grains (0.065–0.13 Gm.).

Off. Prep.—Fluidextractum Veratri Viridis, *U. S.;* Tinctura Veratri Viridis, *U. S.*

VIBURNUM PRUNIFOLIUM. U. S. (Br.)

VIBURNUM PRUNIFOLIUM Viburn. Prun.
[Black Haw]

(vī-bŭr'nŭm prū-nĭ-fō'lĭŭm)

"The dried bark of *Viburnum prunifolium* Linné or of *Viburnum Lentago* Linné (Fam. *Caprifoliaceæ*), without the presence or admixture of more than 5 per cent. of wood or other foreign matter." *U. S.* "Black Haw is the dried bark of Viburnum prunifolium, *Linn.*" *Br.*

Virburnum, *Br.;* Stagbush, Sheep-berry.

Viburnum prunifolium is a tall, very handsome shrub, which is quite common in the Middle and Southern United States, east of the Mississippi, flowering in May and ripening in the early autumn its ovoid or oblong blackish fruit. It is specifically characterized by its acuminate, glabrous winter buds, by its acuminate, sharply serrulate, ovate leaves on long, slender, sometimes broadened and wavy margined petioles. Its sessile cymes are 2 to 5 inches broad and bear oval bluish-black drupes.

Viburnum Lentago L., *Sheep Berry, Sweet Viburnum,* resembles the previous species, but has the winter buds smaller, less acute and often reddish pubescent, and its leaves stouter petioled and not acuminate at the apex. Its geographical limit overlaps that of *V. prunifolium,* but extends much further westward and northward, even to Manitoba. The bark of *V. dentatum* L., or *Arrow wood,* is said to be sometimes substituted for the official drug. (For description of *V. opulus,* see Part II.)

Properties.—The bark is officially described as "in irregular, transversely curved or quilled pieces, from 1.5 to 6 cm. in length, and from 0.5 to 1.5 mm. in thickness; outer surface grayish-brown, or, where the outer cork has scaled off, brownish-red, longitudinally wrinkled; inner surface reddish-brown, longitudinally striated; fracture short but uneven, showing in bark which is young or of medium thickness, a dark brown cork, a brownish-red outer cortex, and a whitish inner cortex in which are numerous light yellow groups of sclerenchymatous tissues; odor slight; taste distinctly bitter and somewhat astringent. The powder is dark brown; under the microscope it exhibits numerous large stone cells, which are often elongated, thick-walled and strongly lignified; bast-fibers few, crystals of calcium oxalate from 0.015 to 0.035 mm. in diameter, occurring mostly in rosette aggregates, occasionally in crystal fibers; monoclinic prisms of calcium oxalate few." *U. S.*

"In quills or curved pieces, one to four millimetres thick; dull brown or reddish-brown. Outer surface longitudinally wrinkled or, in older bark, with shallow fissures and scaly; inner surface longitudinally striated, reddish-brown. Fracture granular. In transverse section, a dark brown outer portion and a whitish or reddish bast with numerous groups of sclerenchymatous cells. Slight odor; taste astringent and bitter." *Br.*

The morphology of viburnum prunifolium is well illustrated by Holm in *M. R.,* xxii, p. 35. Illustrations of the bark of the several species of viburnum are given in Kraemer's "*Scientific and Applied Pharmacognosy*"; also see *P. J.,* 1903, lxx, p. 197. Lloyd states that the bark of all native species of viburnum are collected by root diggers and sold under the name of black haw. (*Ph. Rev.,* xxiii, p. 333.) The bark of the root is preferred to that of the stem and the official definition formerly limited the drug to the root bark. Farwell reported the substitution of the genuine drug by the bark of some other species of viburnum than those specified by the Pharmacopœia. The bark is much darker than the official bark and consisted largely of stem bark. (*M. R.,* xvii, p. 35.)

Herman van Allen found the following constituents in viburnum: (1) a brown resinous body, of a very bitter taste, from which it was found impossible to separate the sugar; (2) a greenish-yellow resin or neutral principle of a bitter taste, slightly soluble in water, freely so in alcohol, called by Krämer *viburnin;* (3) valeric acid; (4) a tannic acid giving a greenish-black color with ferric salts; (5) oxalic acid; (6) citric acid; (7) malic acid; (8) sulphates; (9) calcium, magnesium, potassium, and iron chlorides. (*A. J. P.,* 1880, 443.) As the result of elaborate investigation, T. Shennan (*Royal Coll. Phys. Lab. Rep.,* Edinburgh, vi, 1897) concludes that the *Viburnum prunifolium* contains *viburnic—i.e.,* valeric—acid, and a non-volatile alkaloid which, however, he failed to obtain in a pure condition.

Viburnum has been used quite largely in the treatment of *dysmenorrhea, after-pains,* and other uterine disorders. Pilcher (*A. I. M.,* Jan., 1917), however, has shown that in the doses ordinarily employed it has no effect of any kind on the uterine muscle.

R. L. Payne, Jr., has found that when given in toxic amount to the lower animals viburnum produces muscular weakness, ending in complete paralysis with loss of reflex action, which he believes to be due to an influence upon the motor side of the spinal cord. In warm blooded animals there is also marked lowering of the arterial pressure, believed by Payne to be the result of a direct action of the drug upon the heart. Experiments of Payne have in a measure been confirmed by those of T. Shennan, but as the latter took six drachms of the fluidextract within thirty minutes, with no demonstrable effect except a doubtful decrease of the rate and force of the pulse, it is plain that the drug is very feeble.

The solid extract (*dose,* from three to ten grains (0.2–0.65 Gm.)) does not represent the drug completely, owing to loss of volatile acid;

so that the fluidextract should be preferred, in doses of from one-half to one fluidrachm (1.8–3.75 mils).

Dose, thirty to sixty grains (2.0–3.9 Gm.).

Off. Prep.—Extractum Viburni Prunifolii, *U. S.;* Fluidextractum Viburni Prunifolii, *U. S.* (*Br.*); Elixir Viburni Prunifolii (from Fluidextract), *N. F.*

VINA MEDICATA.

MEDICATED WINES

(vī-nạ mĕd-ĭ-cā′tạ)

Vins médicinaux, Œnolés, *Fr.;* Medicinische Weine, *G.*

All wines were deleted from the U. S. P. IX. The Committee of Revision realized that the time had come to use alcohol of various strengths and to drop the inconvenience of using a liquid for a menstruum of varying quality and which required standardization to bring it to a reasonably definite strength. Another contributory cause for the deletion was the ignoring by pharmacists of the specified varieties of wines which were known to conform to the official requirements. Most pharmacists used sherry wine for Vinum Album and port wine for Vinum Rubrum, although both of these were known to be fortified wines containing nearly 10 per cent. more alcohol than the maximum limit for the officially designated wines of those titles. Both the Br. Pharm. 1914 and the N. F. IV have retained sherry wine as a menstruum, and the former uses also an "Orange Wine" (see *Vinum Aurantii*, page 1201).

The reported advantages of wine as a pharmaceutical menstruum are that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change, while at the same time it is less stimulating than strong or diluted alcohol, owing to its smaller proportion of alcohol. The acid which it usually contains serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition, and even the strongest acquire such a liability from the principles which they extract from vegetable substances; so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant, and the preparations, therefore, made with them were formerly of unequal strength. In the choice of wine, the purest and most generous should be selected. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, from wine of proper strength, and should be kept in a cool place. *Detannated wine* may be best made by digesting the wine with casein which has the advantages of milk, formerly used, without its diluting effect or the introduction of foreign and undesirable constituents. Gelatin has also been used successfully for the same purpose, but is somewhat inferior to casein, which is now obtainable either in the soluble or insoluble form. The former should be used and the latter form may be made soluble by the careful use of an alkali. Ferric hydroxide should never be used for detannating wines, for, while it successfully removes the tannin, it also removes other valuable constituents and the acid of the wine always takes up a little of the iron so that a slightly ferruginous preparation results, which is usually undesirable.

VINUM ANTIMONIALE. Br. (N. F.)

ANTIMONIAL WINE

(vī′nŭm ăn-tĭ-mō-nĭ-ă′lē)

Vinum Antimonii, *N. F. IV;* Wine of Antimony; Vin antimonié, Vin émétique, Vin stibié, *Fr.;* Vinum Stibiatum, *P. G.;* Brechwein, *G.;* Vino emetico, *Sp.*

Wine of Antimony was not admitted to the U. S. P. IX, but has been transferred to the N. F. IV, sherry wine replacing the white wine. The formula of the U. S. P. VIII is given herewith.

"Antimony and potassium tartrate, *four grammes* [or 62 grains]; boiling distilled water, *sixty-five mils* [or 2 fluidounces, 95 minims]; alcohol, *one hundred and seventy-five mils* [or 5 fluidounces, 440 minims]; white wine, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the antimony and potassium tartrate in the boiling distilled water. Add this solution to a mixture of the alcohol with *seven hundred and twenty-five mils* [or 24 fluidounces, 247 minims] of white wine; mix well, and allow the mixture to stand until it has cooled. Then filter and add sufficient white wine through the filter to make the liquid measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms.]"

"Tartarated Antimony, 4 *grammes;* Distilled Water, boiling, 40 *millilitres;* Sherry, sufficient to produce 1000 *millilitres.* Dissolve the Tartarated Antimony in the Distilled Water, and add sufficient Sherry to produce the required volume." *Br.*

The Br. Ph., 1914, and N. F. IV formulas contain about 2 grains of tartar emetic in the fluidounce.

Considerable difficulty is often experienced in effecting a solution of tartar emetic in wine, and precipitation is likely to occur after the solution has been effected. These results are undoubtedly due to the variability in the amount of tannic acid in wines of different type and quality. Paris stated that he had seen the decomposition of the tartar emetic so complete that no traces of the salt could be detected in the supernatant liquid. The difficulty was not avoided by the plan adopted in the U. S. Pharmacopœia VIII of first dissolving the antimonial in water and then adding the wine; for, even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and wine which is low in tannic acid content, to make a permanent solution.

The advantages of antimonial wine are that

it affords the means of administering minute doses of tartar emetic, and that it is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is used only as a diaphoretic or expectorant.

Dose, from ten to thirty minims (0.6–1.8 mils), given frequently.

VINUM AURANTII. Br.

ORANGE WINE

(vī'nŭm âu-răn'tī-ī)

Vin d'Ecorce d'orange amère, *Fr.;* Pomeranzenwein, *G.*

"Orange Wine is made by the fermentation of a saccharine solution to which Fresh Bitter-Orange Peel has been added." *Br.*

This is officially described as "a vinous liquid, having a golden sherry color, and a taste and aroma derived from the Bitter-Orange Peel. Contains from 12 to 14 per cent. by volume of ethyl hydroxide. Not more than slightly acid to *litmus.* When 50 millilitres are made alkaline with *solution of sodium hydroxide,* evaporated to a small bulk, acidified with *hydrochloric acid,* and shaken with *benzene,* the residue obtained on evaporating the benzene solution, when dissolved in *water,* does not assume a violet color on the addition of a drop of *T. Sol. of ferric chloride* (absence of salicylic acid). Yields not more than the slightest characteristic *reactions* for sulphites." *Br.*

This wine is used as a vehicle, and is the official menstruum for several Br. preparations.

VINUM COLCHICI. Br. (N. F.)

COLCHICUM WINE

(vī'nŭm cŏl'çhĭ-cī)

Vinum Colchici Cormi, *N. F. IV;* Wine of Colchicum corm; Vinum Colchici Radicis, U. S. 1890; Wine of Colchicum Root; Vin de Bulbe de Colchique, *Fr. Cod.;* Œnolé de Bulbe de Colchique; Zeitlosenknollenwein, *G.;* Vino con colchico, *It.*

"Colchicum Corm, in No. 20 powder, 200 *grammes;* Sherry, 1000 *millilitres.* Prepare by the *maceration process.*" *Br.*

The British, 1914, colchicum wine is only half the strength of the U. S., 1890, preparation. The latter was intended to be a saturated vinous tincture of colchicum. A wine of colchicum corm is also official in the N. F. IV (see Part III) but it is double the strength of the British wine, *i.e.,* 400 Gm. of corm per 1000 mils of wine. A wine made from the fresh bulb is occasionally imported from England, and is thought by some to be more efficacious than the official preparation. *Wine of Colchicum Seed,* also in the N. F. IV, is made by mixing together 10 mils of fluidextract of colchicum seed, 15 mils of alcohol, and 75 mils of sherry wine. In *gout* this wine is frequently given in connection with magnesium sulphate. It is a violent poison in overdoses. Two fluidrachms and a half (9.3 mils) of it are said to have caused death.

Dose, ten to forty minims (0.6–2.5 mils).

VINUM FERRI. Br.

IRON WINE

(vī'nŭm fĕr'rī)

Vinum Chalybeatum, s. Martiatum; Eisenwein, Stahlwein, *G.*

"Iron, in wire, 50 *grammes;* Sherry, 1000 *millilitres.* In a closed vessel partially immerse the Iron in the Sherry; continue the maceration until the filtered liquid responds to the following test:—Evaporate 50 millilitres to dryness, incinerate the residue, heat the ash with *hydrochloric acid* diluted with an equal volume of *water,* filter, wash the filter paper with *water,* and add to the mixed filtrate and washings excess of *solution of ammonia.* Collect the precipitate, wash, dry and ignite; the residue weighs not less than 0.089 or more than 0.215 gramme, representing a proportion of not less than 0.125 or more than 0.300 gramme of iron, calculated as iron, Fe, in 100 millilitres of the Wine." *Br.*

(See also *Vinum Ferri Citratis.*)

When wine is made to react on metallic iron with presence of air, the metal is oxidized, and then unites with the excess of acid of the potassium bitartrate, which is the characteristic salt of wines. The ferruginous salt, therefore, formed is iron and potassium tartrate, or the tartarated iron of the Br. Pharmacopœia, and this was the old method of preparing the Wine of Iron. But it is obvious that the strength in iron cannot be entirely uniform, as the quantity dissolved must depend on the proportion of the bitartrate in the wine, which is variable, and on various circumstances of the manipulation. In consideration of these objections, it was thought best, in the Br. formula of 1864, to substitute a simple solution in the wine, of the iron and potassium tartrate already formed, and to abandon the old tedious formula. But it is obvious that a solution of the ferruginous salt in wine is not exactly the same as the wine of iron prepared with the metal, as it contains the potassium bitartrate unaltered. For this and other reasons, the Br. Pharmacopœia has returned to the old method.

Dose, one to four fluidrachms (3.75–15.0 mils).

VINUM FERRI CITRATIS. Br. (N. F.)

WINE OF IRON CITRATE

(vī'nŭm fĕr'rī cĭ-trā'tĭs)

Vinum Ferri, *N. F. IV;* Wine of Iron; Vinum Chalybeatum, *Br.;* Wine of Ferric Citrate; Vin Chalybé, Œnolé ferrugineux, Vin ferrugineux, *Fr. Cod.;* Eisenwein, *G.*

"Iron and Ammonium Citrate, 18 *grammes;* Orange Wine, sufficient to produce 1000 *millilitres.* Dissolve. Shake occasionally for three days; filter." *Br.*

This wine was not admitted to the U. S. P. IX but was added to the N. F. IV (see Part III). The formula of the U. S. P. VIII is given herewith.

"Iron and Ammonium Citrate, *forty grammes* [or 1 ounce av., 180 grains]; Tincture

of Sweet Orange Peel, *sixty mils* [or 2 fluidounces, 14 minims]; Syrup, *one hundred mils* [or 3 fluidounces, 183 minims]; White Wine, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the iron and ammonium citrate in *seven hundred mils* [or 23 fluidounces, 321 minims] of White Wine. Add to this the tincture of sweet orange peel, and the Syrup, and, lastly, enough White Wine to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Set the mixture aside for two days; then filter through paper, in a well-covered funnel." *U. S. VIII.*

Dose of the Br. preparation, one to four fluidrachms (3.75–15.0 mils).

VINUM IPECACUANHÆ. Br. (N. F.)

IPECACUANHA WINE

(vī'nŭm ĭp-ę-căc-ū-ăn'hæ)

Wine of Ipecac; Vin (œnolé) d'Ipécacuanha, *Fr.;* Brechwurzelwein, *G.*

"Liquid Extract of Ipecacuanha, 50 *millilitres;* Sherry, 950 *millilitres.* Mix; set aside for forty-eight hours; filter." *Br.*

This wine was not admitted to the U. S. P. IX but was added to the N. F. IV (see Part III). The U. S. P. VIII process was as follows:

"Fluidextract of Ipecac, *one hundred mils* [or 3 fluidounces, 183 minims]; Alcohol, *one hundred mils* [or 3 fluidounces, 183 minims]; White Wine, *eight hundred mils* [or 27 fluidounces, 24 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix them. Set the mixture aside for two days; then filter through paper, in a well-covered funnel."

The wine of ipecac of the U. S. P. VIII and N. F. IV contains in a fluidounce the virtue of about 45 grains, the British, 1914, of only somewhat more than 22 grains. Wine of ipecac possesses all the medicinal properties of the root, and may be used as a substitute when it is desirable to administer the medicine in a liquid form. It is much used as an expectorant and a diaphoretic, and the effects of the Dover's powder may be obtained by combining it with a liquid preparation of opium.

VINUM QUININÆ. Br.

QUININE WINE

(vī'nŭm quĭ-nī'næ)

Vin (Œnolé) de Quinine, *Fr.;* Chininwein, *G.*

"Quinine Hydrochloride, 2 *grammes;* Orange Wine, 875 *millilitres.* Dissolve; filter if necessary." *Br.*

The Br. Ph., 1898, replaced quinine sulphate used in the 1885 process by quinine hydrochloride on account of the greater solubility of the latter. Each fluidounce contains one grain of quinine hydrochloride.

Dose, one-half to one fluidounce (15–30 mils).

VINUM XERICUM. Br., N. F.

SHERRY WINE Vin. Xeric.

(vī'nŭm xĕ'rĭ-cŭm)

"Sherry is a Spanish wine." *Br.* "An alcoholic liquid made by fermenting the juice of fresh ripe grapes, the fruit of cultivated species of *Vitis* Linné (Fam. *Vitaceæ*), freed from seeds, stems and skins, and fortifying with pure grape brandy. It contains not less than 16 per cent. nor more than 24 per cent. of C_2H_5OH, by volume, when estimated (for alcohol) as directed in the U. S. Pharmacopœia IX. Preserve it in well-closed casks or in well-stoppered bottles, in a cool place." *N. F. IV.*

"Pale yellowish-brown, containing not less than 16 per cent. by volume of ethyl hydroxide. Contains in 100 millilitres not less than 0.1 or more than 0.2 gramme of volatile acids, calculated as acetic acid, $HC_2H_3O_2$, and not less than 0.3 or more than 0.45 gramme of fixed acids, calculated as tartaric acid, $H_2C_4H_4O_6$, when tested by the following process:—(1) Titrate 25 millilitres of the Sherry with *N/5 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator, and note the number (*a*) of millilitres of the former solution required. (2) Introduce 25 millilitres of the Sherry with 25 millilitres of *water* into a flask capable of holding 200 millilitres and attach a condenser; add 0.5 gramme of *tannic acid,* and distil gently until about 25 millilitres have been collected. Then pass a current of steam through the residual liquid in the flask, and continue the distillation until about 200 millilitres in all have been collected. Titrate the distillate with *N/5 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. The number (*b*) of millilitres of the former solution required is not less than 2.1 or more than 4.2, representing a proportion of not less than 0.1 or more than 0.2 gramme of volatile acids, calculated as acetic acid, $HC_2H_3O_2$, in 100 millilitres of the Sherry. Deduct the number (*b*) of millilitres required in (2) from the number (*a*) of millilitres required in (1). The difference is not less than 5 or more than 7.5, representing a proportion of not less than 0.3 or more than 0.45 gramme of fixed acids, calculated as tartaric acid, $H_2C_4H_4O_6$, in 100 millilitres of the Sherry. When 50 millilitres of the Sherry are made alkaline with *solution of sodium hydroxide,* evaporated to a small bulk, acidified with *hydrochloric acid* and shaken with *benzene,* the residue obtained on evaporating the benzene solution, when dissolved in *water,* does not assume a violet color on the addition of a drop of *T. Sol. of ferric chloride* (absence of salicylic acid)." *Br.*

In the U. S. P. VIII two varieties of wine were officially recognized, respectively designated as *vinum album* and *vinum rubrum.* Although the descriptions and tests of both of these articles included only natural wines of low alcohol content (10 to 12 per cent.), most pharmacists continued to use sherry and port wine

respectively for the white and red wine, and as both sherry and port are fortified wines containing over 20 per cent. of alcohol, lack of conformity to official character of product in the class of preparations made from these wines was the rule rather than the exception. For this reason wine was deleted from the U. S. P. IX, but sherry has been admitted to the N. F. IV.

"Sherry Wine is a pale yellowish-brown or amber-colored liquid, having a pleasant, aromatic odor, free from yeastiness, and having a fruity, characteristic taste without excessive sweetness or acidity. Specific gravity: from 0.985 to 1.000 at 25° C. (77° F.). Evaporate 100 mils of Sherry Wine in a tared dish, on a water bath, and dry the residue to constant weight at 100° C. (212° F.); it weighs not less than 3 Gm. nor more than 7 Gm. Ignite this residue at a low temperature and burn it gradually to whiteness, moisten the ash with a small portion of ammonium carbonate T.S. and again carefully ignite; the ash weighs not less than 0.175 Gm. nor more than 0.5 Gm. Dilute 50 mils of Sherry Wine with 200 mils of distilled water; it requires for neutralization not less than 20 mils nor more than 40 mils of tenth-normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator (*free acid*). Acidulate 50 mils of Sherry Wine with hydrochloric acid, heat and add an excess of barium chloride T.S. Collect the precipitate on a filter of known ash content, wash it thoroughly, dry, and ignite; the residue weighs not more than 0.034 Gm. (*sulphate*). To 10 mils of Sherry Wine add an equal volume of distilled water and 5 drops of ferric chloride T.S.; not more than a faint greenish-brown color appears (*tannic acid*). Add 10 mils of diluted sulphuric acid to 75 mils of Sherry Wine and shake out the mixture in a separator twice, using each time 20 mils of a mixture of equal volumes of purified petroleum benzin and ether. Transfer the separated benzin-ether solution to an evaporating dish, allow the solvent to evaporate spontaneously and dissolve the residue in 3 mils of distilled water; the solution does not have a sweet taste (*saccharin*) nor does it yield a violet color upon the addition of a few drops of a dilute solution of ferric chloride (1 in 200) (*salicylic acid*)." *N. F. IV.*

VIRUS VACCINICUM. U. S.

VACCINE VIRUS Virus Vaccin. [Glycerinated Vaccine Virus, Smallpox Vaccine, Jennerian Vaccine]

(vī'rŭs văc-cĭn'ĭ-cŭm)

"The pustules of vaccinia or cowpox from healthy vaccinated animals of the bovine species, removed and prepared under aseptic conditions." *U. S.*

Impfstoff, *G.*; Virus vaccin, *Fr.*; Vaccino, virus di vacca, *It.*; Vacuna, *Sp.*

Though constantly used by the medical profession for more than a century, this article is now first admitted into the United States Pharmacopœia in the Ninth Decennial Revision. Vaccination against smallpox is the oldest and the surest method of preventive medicine, directed against a specific disease. Its efficacy was first proven by Jenner in England in 1796, and soon corroborative evidence was supplied from America, notably by Waterhouse of Boston. Up to the middle of the nineteenth century, the vaccine material was commonly taken from the arm of a person previously vaccinated and thus carried on from patient to patient. At present the calf serves exclusively in this country as the animal for propagating the virus to be used on human subjects; the danger of transmitting some other latent disease of man at the same time is thus avoided. Other improvements which have occurred in the course of time are the use of the more potent pulp, instead of the lymph of the vesicle on the calf, and especially the use of glycerine as a preservative. The glycerine is allowed to act on the virus for a number of days before use, and by this means the bacteria, normally present on the skin of the calf from which the virus is taken, are very greatly reduced in number. Phenol and ether have also been used to obtain a nearly sterile vaccine. The dry vaccine point is no longer allowed to be sold in interstate traffic; this form of vaccine either contained a large number of organisms or was comparatively inert. Moist points are still used, but the preferable form of container is one in which the virus is sealed in glass, such as in a capillary tube; insertion by single incision or by rotary abrasion is thus made easy and the large areas of scarification avoided.

Preparation.—"The vaccine pulp should be thoroughly rubbed up in a mortar or passed through a special grinder, strained to remove coarse particles, and made into a smooth emulsion with a glycerin solution. Vaccine Virus gradually loses in potency, the loss being more rapid at high than at low temperatures. Preserve it at a temperature between 4.5° and 15° C. (40° and 59° F.), protected from light. Only such Vaccine Virus may be sold as has been prepared in establishments licensed by the Secretary of the Treasury of the United States. The law and the regulations demand that the following requirements be observed: No Vaccine shall be used from any animal having a communicable disease, or suspected of having a communicable disease, other than vaccinia; animals used for propagating Vaccine Virus must be under daily veterinary examination for a period of not less than seven days before vaccination, and as soon as the vaccine pulp is removed a necropsy shall be made on each animal and permanent records kept. Each lot of Vaccine Virus shall be examined to determine its freedom from pathogenic micro-organisms and a special examination must be made of each lot to determine the absence of tetanus spores or toxin, and permanent records must be kept of these examinations. The Virus must be marketed in sterile containers that comply with the requirements of the law and the regulations established by the United States Public Health Service. Each package of Vaccine Virus shall

bear upon the label the name, address, and license number of the manufacturer and the date beyond which the contents cannot be expected to yield their specific results. The label should also contain the laboratory number of the Virus." *U. S.*

The propagation of vaccine virus requires sterile laboratory equipment and careful technic throughout. The animals must be tuberculin tested, repeatedly inspected and kept very clean; the removal, grinding, and distribution of the vaccine into its final containers are strict aseptic operations.

Uses.—To appreciate what vaccination has done for mankind, it is necessary to consider the era before vaccination, when having had smallpox was one of the evidences of maturity, and the toll of lives yearly demanded by this disease was a constant drain on every class of humanity. In more recent times the regions where vaccination is little practiced are conspicuous for the number of pock-marked faces; opposition to vaccination was so general in Montreal that when in 1886 a Pullman car conductor brought smallpox from Chicago, an epidemic broke out which in nine months killed 3164 persons. As a contrast to this may be cited the experience of smallpox hospitals, where doctors, nurses, and attendants never having had smallpox are kept immune by vaccination. Smallpox among the unvaccinated is the most contagious disease known, yet vaccination is often too lightly regarded in that it is carelessly performed and no attention is given the patient after the operation. Any wound is liable to complications; a wound intentionally given should be particularly guarded against infection. Vaccination by scarification or cross-hatching, which forms an ulcerating area of appreciable extent—and the use of vaccination shields or other inappropriate after-care are the most frequent causes of sore arms. To vaccinate, the skin of the upper arm near the insertion of the deltoid muscle should be cleansed and dried. Soap and water, alcohol, or ether may be used for this purpose, but no stronger antiseptic should be applied. The cotton or cloth with which the skin is wiped should be sterile and nothing else allowed to touch the site. The capillary tube may be wiped with alcohol, the ends broken inside the bulb, and the glycerinated virus expelled by the bulb to form a line on the cleansed skin. Drawing the skin tight by grasping the arm beneath, a single incision about an inch long and parallel with the arm is made through the virus. This incision may be made with a flamed needle or other sterile instrument and should penetrate the papillary layer, but preferably not draw blood. The virus should be thoroughly rubbed into the incision with a smooth sterile instrument, such as the side of the needle. No other incision or cross scratching should be made unless there will be no opportunity for re-vaccination; in the latter case similar single incisions may be made on either side of the first and at least an inch away; other tubes should be used for this purpose. By this means the pustulation is limited so that large confluent crusts are not formed and deep ulceration with the tendency to secondary infection is avoided. Another method which produces even a smaller wound, but is surely successful only with very fresh virus is inoculation by the twisting abrasion. A dentist's drill (sterilized each time by flaming or other method) is used for this purpose. A slight twirling motion between the thumb and forefinger causes this instrument when pressed against the skin to give a shallow area denuded of epidermis, but without bleeding, no larger than a pinhead. To this the virus can be applied and rubbed in as above described. The vaccination area should dry (not in direct sunlight) for fifteen minutes or half an hour before being covered with clothing. The arm must be kept clean, dressed aseptically when the vesicle appears, and, when pustulation ensues, treated antiseptically. No dressing should be allowed to remain on the arm more than forty-eight hours. The arm should be seen by the physician on the third, sixth and ninth day at least, to determine the character of the reaction, and as often as may be necessary thereafter to insure rapid healing of the wound. It is preferable if the whole process can take place without the crust breaking. Vaccination is a surgical procedure and is worthy not only of the painstaking asepsis of a skilled physician, but of his intelligent after-care as well. If never previously vaccinated, the patient usually shows a papule about the fourth day, a vesicle about the fifth, and a pustule the eighth. Re-vaccination may be more rapid in its course, and correspondingly milder; in some cases a small papule is seen on the second day, subsiding without further progress. These abortive accelerated reactions may be taken as indicative of a degree of immunity.

The protection given by vaccination is relative, not absolute, and re-vaccination should be done when exposure to smallpox takes place or is threatened. All infants except in the presence of eczema or marasmus should be vaccinated before teething begins; re-vaccination should be performed before entering school and again at the age of fifteen.

Vaccine virus is the most rapidly deteriorating product likely to be carried by the pharmacist, and should be kept in the coldest part of an ice-box, at a temperature below 5° C. (41° F.).

XANTHOXYLUM. U. S.

XANTHOXYLUM Xanthox. [Prickly Ash Bark]

(xăn-thŏx'ȳ-lŭm)

"The dried bark of *Xanthoxylum americanum* Miller, known in commerce as Northern Prickly Ash Bark, or *Xanthoxylum Clava-Herculis* Linné, known in commerce as Southern Prickly Ash Bark (Fam. *Rutaceæ*)." *U. S.*

X. americanum: Toothache Tree, Angelica Tree, Suterberry, Pellitory Bark, Yellow-wood; Clavalier, Frêne épineux, *Fr.*, Zahnwehholz, Zahnwehrinde, *G.*

X. Clava-Herculis: Sea Ash, Hercules' Club, Pepper-wood.

Northern Prickly Ash (*Xanthoxylum americanum*) is a shrub from five to twenty-five feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface.

The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polygamous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. The capsules are stipitate, oval, punctate, of a greenish-red color, with two valves, and one oval blackish seed. This species of xanthoxylum is indigenous, growing in woods and in moist shady places throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odor, recalling that of oil of lemon.

Botanists are not agreed concerning the distinction of the genus Fagara from Xanthoxylum. Thus, the authors of the Index Kewensis consider the two genera identical, while Engler and Prantl separate them. The most important character separating them seems to be the absence of sepals in Xanthoxylum. Most of the species of the genus Fagara are tropical trees.

Z. Clava-Herculis L. [*Fagara Clava-Herculis* (L.) Small], or Southern Prickly Ash, varies in size from a large bush to a small tree. Its bark is armed with warty prickles, and large conical cork wings occur on the branches and the petioles. The alternate leaves have from seven to nine ovate-lanceolate, crenate-serrulate, unequal-sided leaflets, smooth and shining on the upper surface. It grows on dry soil, westward as far as Western Texas, and perhaps into Mexico, eastward to the Atlantic coast, and northward to Southern Virginia, especially affecting the coast region.

The fruits (*Prickly ash berries*) of both of the official species probably contain the same principles found in the barks. The dried berries are recognized by the N. F. under the name of *Xanthoxyli Fructus,* and are described in Part II.

There has been much confusion in regard to the nomenclature of the prickly ashes. *Aralia spinosa* L., or angelica tree, which grows in the Southern States, is occasionally confounded with *X. Clava-Herculis,* in consequence partly of being sometimes called, like the latter, *prickly ash.* Its bark is nearly smooth externally, is beset with slender prickles in transverse rows and has a taste different from that of *F. Clava-Herculis.* Besides the official trees, the bark of *F. flava* (Vahl), Frug. and Urban (*X. caribæum* S. Wats.), the *satin-wood* of semi-tropical Florida and the West Indies, has appeared in commerce under the name of *yellow Hercules club* or *yellow thorn.* This bark is thin, with an odor like that of Angustura bark, a bitter, disagreeable, acrid taste, and a canary-yellow color, which it imparts to the saliva when chewed. It would seem, also, that under the name of *prickly yellow wood, yellow wood,* or *fustic,* the products of other West Indian xanthoxylums and allied plants find their way into commerce.

Xanthoxylum veneficum Bailey, of Australia is, according to J. H. Maiden, a violent convulsive poison, 5 grains of the extract being a fatal dose for a cat. *Xanthoxylum scandens* is said to be used by the natives of Java as a fish poison, and according to Van der Haar, contains an alkaloid. (*P. J.*, 71, 134; 73, 814.)

Properties.—Although the bark of the Southern prickly ash was not recognized by the U. S. Pharmacopœia until the revision of 1880, as long ago as 1864 Bridges pointed out that it had entered commerce, and gave the physical characteristics separating it. (*Proc. A. Ph. A.*, xii, p. 270.) The characteristics of the two barks are very well given in the following official description.

"**Northern Prickly Ash Bark.**—In transversely curved fragments or quills, from 2 to 15 cm. in length; bark from 0.5 to 2 mm. in thickness; outer surface light gray to brownish-gray with grayish patches of foliaceous lichens bearing numerous small black apothecia; longitudinally wrinkled and with numerous whitish lenticels; the cork occasionally abraded, showing the yellowish or orange inner bark; inner surface yellowish-white, finely longitudinally striate and usually with numerous, bright, shining crystals; fracture short, uneven; odor slight; taste bitter, acrid, becoming pungent. Under the microscope, transverse sections of Northern Prickly Ash Bark show an outer corky layer consisting of from 4 to 20 rows of cells, the tangential walls being more or less thickened and lignified; a wide strata of collenchyma inside of the cork cambium composed of from 8 to 10 rows of tangentially elongated cells, with very thick walls and containing plastids; a more or less indistinct row of endodermal cells beneath which occur small groups of primary bast-fibers; the inner bark consists of numerous parenchyma cells among which are included large oil-secretion reservoirs, separated by medullary rays which are mostly one cell in width; the parenchyma cells as well as the oil-secretion reservoirs contain numerous colorless oily globules. Scrapings from either the inner or outer surface show numerous rod-shape crystals and flat prisms, from 0.015 to 0.25 mm. in length, which polarize light with a display of bright colors.

"**Southern Prickly Ash Bark.**—In transversely curved or irregular, oblong, flattened pieces, or in quills from 2 to 40 cm. in length, bark from 1 to 4 mm. in thickness; outer surface light gray to brownish-gray, marked by

numerous large, barnacle-shaped projections of cork, from 0.5 to 3.5 cm. in thickness, otherwise with numerous grayish patches of foliaceous lichens, bearing blackish apotheeia, and numerous, elliptical lenticels; inner surface light yellowish-brown to olive brown, obscurely longitudinally striate and free from crystals; odor and taste as in Northern Prickly Ash Bark. Under the microscope, transverse sections of Southern Prickly Ash Bark show a strong development of lignified cork occurring in the form of rings, the successive layers being separated by several rows of narrow tabular cells strongly thickened on the tangential walls; beneath the cork cambium occurs a thin layer of collenchyma followed by the outer tissues of the primary cortex and consisting of small groups of rather large stone cells and occasional, scattered groups of bast-fibers and parenchyma; the inner bark consists of parenchyma, a more or less indistinct leptome or sieve tissue among which are numerous, large, light yellowish oil-secretion reservoirs, medullary rays from 1 to 2 cells in width and occasional groups of stone cells and bast-fibers; starch grains numerous, nearly spherical, from 0.002 to 0.01 mm. in diameter, and occurring in the parenchyma cells and medullary rays; calcium oxalate chiefly in monoclinic prisms from 0.01 to 0.025 mm. in diameter, occurring in crystal fibers and in parenchyma cells of the primary cortex. Powdered Xanthoxylum is light grayish-brown, under the microscope it shows mostly irregular fragments of cork cells, nearly colorless and strongly lignified, fragments of parenchyma containing either small starch grains, oily globules or monoclinic prisms of calcium oxalate; stone cells in small groups with thick, colorless walls and containing frequently a reddish-brown substance; bast-fibers few and non-lignified. In the Northern Prickly Ash, the stone cells are usually absent, and the calcium oxalate crystals and the fragments of cork are relatively few." *U. S.*

Xanthoxylum is practically never adulterated, and hence the drug has never been studied very exhaustively. Kraemer illustrates the inner structure of the Southern prickly ash bark in his work on *"Scientific and Applied Pharmacognosy."* Recently the bark of a tropical American species, *X. Ochroxylum* D. C., has been the subject of a pharmocognostical study by Leprince. (*Repert. Pharm.*, 1912, xxiv, p. 215.)

W. L. Cliffe after careful examination demonstrated that the bark of Southern prickly ash exceeded that of the Northern prickly ash in active properties. (*A. J. P.*, 1901, 562.) In 1829, Edward Staples isolated from *X. americanum* a crystalline *xanthoxyline* which was again found by J. U. Lloyd in 1876. Subsequently, from the same plant Edward T. Moffet (*A. J. P.*, 1886, 417) obtained a supposed alkaloid in yellow crystals, soluble in alcohol and chloroform, insoluble in petroleum benzin, ether, and benzene. G. H. Colton (*A. J. P.*, 1880, p. 191) separated from the Southern prickly ash, tasteless, colorless, silky acicular crystals, soluble in alcohol, ether, and chloroform, less soluble in benzene, and insoluble in water. The identity of all these principles was assumed until E. G. Eberhardt (*A. J. P.*, 1890, 231) obtained from the Southern prickly ash a colorless crystalline principle agreeing in solubilities with that of Colton. On analysis it gave figures indicating the formula $C_{20}H_{19}O_6$ or $C_{30}H_{28}O_6$. At the same time he analyzed a sample of Lloyd's crystalline principle from *X. fraxineum* (*X. americanum* Mill.), which had been preserved in the cabinet of the Philadelphia College of Pharmacy, and found for it the formula $C_{20}H_{27}O_6$. Numerous reactions also indicated that the two principles were different. Thus, Lloyd's crystals dissolve in concentrated sulphuric acid with light red color, and on the addition of an excess of water produce a whitish precipitate which is taken up by chloroform; the crystals from the *X. Clava-Herculis,* dissolve in concentrated sulphuric acid with dark red color, and on dilution separate a purplish precipitate, which is not taken up by chloroform. Lloyd's principle melts, moreover, at 129.5° C. (265.1° F.), while Eberhardt's melts at 119° C. (246.2° F.). In 1863, J. D. Perrin separated from the Caribbean *Xanthoxylum Clava-Herculis* an alkaloid which he considered to be *berberine.* This had also been described as early as 1826 by Chevallier and Pelletan under the name of *xanthopicrite. X. senegalense* (*artar root*) was analyzed by Giacosa and Soave (*A. J. P.*, 1890, 500), who found a fixed oil, a neutral crystalline substance, melting at 120° C. (248° F.), and two alkaloids. The first of these they call *artarine,* and give to it the formula $C_{20}H_{17}O_4N$ (which makes it agree with *berberine*), or $C_{21}H_{23}O_4N$, in which case they consider that it may be *methylhydroberberine.* The second alkaloid, crystallizing in blood-red needles, they did not analyze.

Uses.—Xanthoxylum is stimulant, producing, when swallowed, a sense of heat in the stomach, with more or less general arterial excitement, and a tendency to diaphoresis. It is thought to resemble mezereum and guaiac in its remedial action, and is given in the same diseases. As a remedy in *chronic rheumatism,* it enjoys some reputation in this country. The bark, used as a masticatory, is a popular remedy for *toothache.* Xanthoxylum is capable of being used as a counter-irritant, and great relief is sometimes afforded in various forms of chronic pelvic disease in women by means of a hot pack, applied to the lower part of the trunk, of two to four ounces of fluidextract of xanthoxylum and an ounce of tincture of cayenne pepper to two quarts of water. A decoction prepared by boiling an ounce in three pints of water down to a quarter may be given in the quantity of a pint (473 mils), in divided doses, during the twenty-four hours.

Dose, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Fluidextractum Xanthoxyli, *U. S.;* Elixir Corydalis Compositum, *N. F.*

ZINCI ACETAS. U. S., Br.

ZINC ACETATE Zinc. Acet.

(zĭn'cī ă'cę-tăs)

"It contains not less than 83.16 per cent. nor more than 87.32 per cent. of anhydrous zinc acetate, corresponding to not less than 99.5 per cent. of the crystallized salt [$Zn(C_2H_3O_2)_2 + 2H_2O = 219.45$]. Preserve it in well-closed containers." *U. S.* "Zinc Acetate, $Zn(C_2H_3O_2)_2,2H_2O$, may be obtained by neutralising acetic acid with zinc carbonate." *Br.*

Acetas Zincicus; Acétate de Zinc, *Fr. Cod.;* Zincum Aceticum, *P. G.;* Zinkacetat, Essigsaures Zink, Essigsaures Zinkoxyd, *G.*

A process for this salt is no longer given in the U. S. P. In the U. S. process of 1870 zinc oxide—instead of the carbonate as in the Br. process—is acted upon directly by acetic acid. During the evaporation of the solution of the zinc acetate, a small portion of the acetic acid is lost; and hence the necessity of acidulating with a few drops of acetic acid before crystallizing. Though not economical, these processes have the recommendation of being easily performed, and of yielding a pure product. In relation to zinc acetate, see a paper by Ambrose Smith, *A. J. P.* (vii, 14).

Properties.—Zinc acetate is in "soft, white, six-sided, monoclinic plates, of a pearly luster, having a faintly acetous odor, and, in dilute solutions, an astringent, metallic taste. When exposed to the air, the salt gradually effloresces and loses some of its acid. One Gm. of Zinc Acetate dissolves in 2.3 mils of water and in 30 mils of alcohol at 25° C. (77° F.); also in 1.6 mils of boiling water and about 1 mil of boiling alcohol. Its aqueous solution is neutral or slightly acid to litmus. When heated, the salt is partially fused, losing water and acid. At a higher temperature it is decomposed, with evolution of inflammable and empyreumatic vapors, and leaving a residue consisting chiefly of zinc oxide. An aqueous solution of the salt (1 in 20) yields a white, gelatinous precipitate with potassium ferrocyanide T.S. and a white precipitate with ammonium sulphide T.S. Add 0.1 Gm. of the salt to 1 mil of sulphuric acid and 1 mil of alcohol and warm the mixture; ethyl acetate is formed, recognizable by its odor. Ammonium carbonate T.S., when added in small portions to an aqueous solution of the salt (1 in 20), produces at first a white precipitate, which redissolves completely upon the addition of an excess of the reagent. Ten mils of an aqueous solution of the salt (1 in 50), to which 1 mil of hydrochloric acid has been added, does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"Assay.—Dissolve about 1 Gm. of Zinc Acetate, accurately weighed, in 100 mils of distilled water, render the solution slightly alkaline with ammonia water and warm it to 80° C. (176° F.). Completely precipitate the zinc as zinc sulphide by the addition of ammonium sulphide T.S. and warm the liquid on a water bath until the precipitate settles. Collect the latter on a filter, wash it with distilled water containing a few drops of ammonium sulphide T.S., then dissolve it in hot, dilute nitric acid (1 in 3), evaporate the solution to dryness in a tared platinum dish, ignite the residue and weigh it as zinc oxide. The amount of zinc oxide obtained corresponds to not less than 83.16 per cent. nor more than 87.32 per cent. of $Zn(C_2H_3O_2)_2$.

"Each gramme of Zinc Acetate corresponds to not less than 0.369 Gm. nor more than 0.387 Gm. of zinc oxide.

"Zinc Acetate may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"Thin, translucent, colorless, crystalline plates, of a pearly lustre. Taste sharp and unpleasant. Soluble in 2.5 parts of *water.* Yields the *reactions* characteristic of zinc and of acetates. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium chlorides, or sulphates. *Arsenic limit* 5 parts per million. 0.5 gramme, tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

The Br. Pharmacopœia (1898) gives in its formula for zinc acetate three molecules of water. Although the U. S. Pharmacopœia of 1880 adopted the formula giving to zinc acetate three molecules of water, Dibbit states that it contains but two molecules. Franchimont has confirmed this, and proved that both of these two molecules are lost at the temperature of 100° C. (212° F.). (*Ber. d. Chem. Ges.*, 1879, p. 11; *A. J. P.*, May, 1879.) The U. S. P. IX adopted this view, and recognize two molecules, and also the Br. Pharm. 1914. The precipitate thrown down by ammonia from the pure salt is entirely redissolved by an excess of the precipitant, but if ferric oxide be present it will be left undissolved. Zinc acetate is decomposed by the mineral acids, with the escape of acetous vapors.

Uses.—Zinc acetate is used almost exclusively as a local remedy. It is employed principally as an astringent collyrium in *ophthalmia,* and as an injection in *gonorrhea,* after the acute stage in these affections has passed. The strength of the solution usually prescribed is one or two grains to a fluidounce (0.065 or 0.13 Gm. to 30 mils) of distilled water.

ZINCI CARBONAS PRÆCIPITATUS. U. S. (Br.)

PRECIPITATED ZINC CARBONATE Zinc. Carb. Præc.

(zĭn'cī căr'bo-năs præ-cĭp-ĭ-tā'tŭs)

"Precipitated Zinc Carbonate is of somewhat variable chemical composition, corresponding to not less than 68 per cent. of ZnO (81.37)." *U. S.*

"Zinc Carbonate is a hydrated zinc carbonate, and may be obtained by the interaction of zinc sulphate and sodium carbonate." *Br.*

Zinci Carbonas, *Br.*, Zinc Carbonate; Zinci Carbonas Præcipitata, *U. S.* 1870; Carbonate of Zinc; Zincum Carbonicum, Carbonas Zincicus; Carbonate (sous-) de Zinc Hydraté, Hydrocarbonate de Zinc, *Fr. Cod.*; Carbonate de Zinc, *Fr.*; Zinkcarbonat, Kohlensaures Zinkoxyd, *G.*

Calamina, U. S. 1850, was dropped from the U. S. Pharmacopœia in 1860 on account of its impurities, and in the 1880 revision the formula for its substitute was also omitted. Calamine has again come into some use and is official in the N. F. IV as *Calamina Præparata* (*Lapis Calaminaris*). In the U. S. formula of 1870 a double decomposition takes place between zinc sulphate and sodium carbonate, resulting in the formation of sodium sulphate in solution, and basic zinc carbonate which is precipitated. Sodium carbonate is preferable to potassium carbonate for decomposing the sulphate, since the former gives rise to sodium sulphate, which is more easily washed away than the potassium sulphate derived from the latter. Boiling water is properly used in the process, in order to obtain a pulverulent precipitate, which is readily washed. If cold solutions are used, a gelatinous precipitate is formed, which is washed with difficulty. When a solution of zinc sulphate is precipitated by an excess of acid potassium carbonate, a normal zinc carbonate is obtained. With normal sodium carbonate, on the other hand, taken as a precipitant, a basic salt results.

Properties.—It is officially described as "an impalpable, white powder without odor or taste. It is permanent in the air. Precipitated Zinc Carbonate is insoluble in water or in alcohol; completely dissolved by diluted acids with copious effervescence; soluble in ammonia water and in ammonium carbonate T.S. When strongly heated, the salt loses water and carbon dioxide, and leaves a residue, which is yellow while hot, but becomes white on cooling. For making the following tests for identity, make a solution by adding 10 mils of diluted sulphuric acid and 10 mils of distilled water to 1.5 Gm. of Precipitated Zinc Carbonate, and, after effervescence has ceased, remove the undissolved excess by filtration. In portions of this solution a white gelatinous precipitate is produced by potassium ferrocyanide T.S., and a white precipitate by ammonium sulphide T.S. Another portion of this solution yields with ammonium carbonate T.S. a white precipitate, which redissolves completely in an excess of the reagent. Ten mils of a solution of the salt (1 in 50) made with the aid of a slight excess of hydrochloric acid does not respond to the Test for heavy metals (see Part III, Test No. 3). Mix 1 Gm. of the salt in a flask with 10 mils of boiling distilled water and add 2 drops of phenolphthalein T.S.; not more than 1 mil of tenth-normal hydrochloric acid V.S. is required to discharge any red color that may be produced (*alkali*).

Assay.—"Digest about 2 Gm. of Precipitated Zinc Carbonate, accurately weighed, with 50 mils of normal sulphuric acid V.S. until solution is complete; then titrate the excess of sulphuric acid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 68 per cent. of ZnO.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.040685 Gm. of ZnO. Each gramme of Precipitated Zinc Carbonate corresponds to not less than 16.8 mils of normal sulphuric acid V.S." *U. S.*

"White amorphous powder. No odor or taste. Insoluble in *water;* entirely soluble in *diluted nitric acid.* Yields the *reactions* characteristic of zinc and of carbonates. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, or ammonium, and not more than the slightest *reactions* for chlorides or sulphates. *Arsenic limit* 10 parts per million. 0.2 gramme, dissolved in *diluted sulphuric acid,* and tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

If adulterated with chalk it will be only partly soluble in oxalic acid solution. Precipitated zinc carbonate is often sold under the incorrect name of *flowers of zinc,* a name which properly belongs only to the oxide, as obtained by combustion. When obtained from solutions of zinc sulphate and sodium carbonate it has a variable composition, as different hydrated basic carbonates are formed, according to the temperature used, etc.; the higher the temperature and the larger the quantity of water used, the more basic the carbonate becomes.

Uses.—This was introduced as a substitute for prepared calamine, but, as one of the important virtues of the native product was its pinkish color, the substitution is not a step in advance. It is used locally for much the same purpose as zinc oxide.

ZINCI CHLORIDUM. U. S., Br.

ZINC CHLORIDE Zinc. Chlor.

(zĭn'cī ȼhlō'rı̣-dŭm)

"It contains not less than 95 per cent. of $ZnCl_2$ (136.29). Preserve it in small, glass-stoppered bottles." *U. S.* "Zinc Chloride, $ZnCl_2$, may be obtained by the interaction of hydrochloric acid and zinc." *Br.*

Butter of Zinc; Chloruretum Zincicum; Chlorure de Zinc, *Fr. Cod.*; Zincum Chloratum, *P. G.*; Zinkchlorid, Chlorzink, *G.*; Cloruro zincico, *Sp.*

The British Pharmacopœia does not give a detailed process for making this salt; that of the Br. Pharm. 1885 follows:

"Take of Granulated Zinc *one pound* [avoirdupois]; Hydrochloric Acid *forty-four fluid ounces* [Imperial measure]; Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce* [av.], or *a sufficiency;* Distilled Water *one pint* [Imp. meas.]. Put the Zinc into a

porcelain basin, add by degrees the Hydrochloric Acid previously mixed with the water, and aid the action by gently warming it on a sand-bath until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow it to stand on a cool part of a sand-bath for twenty-four hours, stirring frequently. Test a few drops of the resulting liquid for iron or lead by adding excess of ammonia and then sulphydrate of ammonium, when a black precipitate will be produced if iron or lead be present.

In the latter case filter the remainder of the product into a gallon bottle, and pour in the solution of chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odor of chlorine. Add the carbonate of zinc, in small quantities at a time, and with renewed agitation, until a brown sediment appears, and the whole of the iron or lead is thus precipitated. Filter through paper into a porcelain basin, and evaporate until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid. Pour it out now into proper moulds, and when the salt has solidified, but before it has cooled, place it in closely-stoppered bottles. If no iron or lead be present, filter and evaporate, etc., at once." *Br.* 1885.

In the U. S. process of 1870 the zinc chloride is obtained by evaporating the previously formed solution. The British first prepares the zinc chloride in solution, and in order to get rid of the iron uses chlorine, which combines with the iron to form ferric chloride, and, zinc carbonate being added, the zinc combines with the chlorine to increase the product of zinc chloride, while ferric oxide is deposited and carbon dioxide is set free. As this preparation is used chiefly as a caustic, it is melted and cast into moulds as the last step in the Br. process. Rhighini prepares this chloride by double decomposition between solutions of barium chloride and zinc sulphate. Barium sulphate is precipitated, and zinc chloride remains in solution, from which it is obtained in white flaky crystals by due evaporation. As zinc sulphate is obtainable in considerable quantities as a cheap by-product in the washing of pyrites and other sulphide ores containing zinc, as well as from the so-called "pickle waste" solutions from brass foundries, this is sometimes used as a commercial source for the manufacture of zinc chloride. Finely ground salt is added to the zinc sulphate solution, and the mixture chilled, when the sodium sulphate produced by the reaction crystallizes out, leaving zinc chloride in solution.

Properties.—It is "a white, or nearly white, granular powder, or in porcelain-like masses, or moulded into pencils; odorless; *it is so intensely caustic as to make tasting dangerous,* unless the salt is dissolved in a large quantity of water. It is very deliquescent. One Gm. of Zinc Chloride dissolves in 0.25 mil of water, and in about 1.3 mils of alcohol at 25° C. (77° F.); freely soluble in glycerin. An aqueous solution of the salt (1 in 10) is acid to litmus. When heated to 115° C. (239° F.), Zinc Chloride fuses to a clear liquid. At a higher temperature it is partly volatilized in dense, white fumes, and partly decomposed, leaving a residue of zinc oxide. An aqueous solution of the salt (1 in 20) yields a white, gelatinous precipitate, with potassium ferrocyanide T.S. and a white precipitate with ammonium sulphide T.S. With silver nitrate T.S. an aqueous solution of the salt (1 in 20) yields a white, curdy precipitate insoluble in nitric acid but readily soluble in ammonia water. Mix an aqueous solution of the salt (1 in 20) with an equal volume of alcohol; a single drop of hydrochloric acid is sufficient to render 10 mils of the mixture perfectly clear (*oxychloride*). Completely precipitate the zinc from a solution of 1 Gm. of the salt in 50 mils of distilled water, by means of ammonium sulphide, filter, evaporate the filtrate, and gently ignite; not more than 0.004 Gm. of residue remains. Ten mils of an aqueous solution of the salt (1 in 50) to which 1 mil of diluted hydrochloric acid has been added does not respond to the Test for heavy metals (see Part III, Test No. 3). Add ammonium carbonate T.S., in small portions, to an aqueous solution of Zinc Chloride (1 in 20); the precipitate produced is white, and redissolves completely in an excess of the reagent. Add sufficient potassium hydroxide T.S. to 5 mils of an aqueous solution of the salt (1 in 10) to redissolve the precipitate which first forms, and then warm the solution; the odor of ammonia is not perceptible (*ammonium salts*). Ten mils of an aqueous solution of the salt (1 in 20), acidulated with 1 mil of hydrochloric acid, is not rendered more than slightly turbid by the addition of 1 mil of barium chloride T.S. (*sulphate*).

"**Assay.**—Proceed as directed under the Assay for chlorides (see Part III, Test No. 5), using about 0.3 Gm. of Zinc Chloride, accurately weighed, in a stoppered weighing-bottle. It shows not less than 95 per cent. of $ZnCl_2$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.0068145 Gm. of $ZnCl_2$. Each gramme of Zinc Chloride corresponds to not less than 139.4 mils of tenth-normal silver nitrate V.S." *U. S.*

"Colorless opaque rods or tablets, or in granules; very deliquescent and caustic. Almost entirely soluble in *water,* in *alcohol* (90 per cent.), and in *ether.* Yields the *reactions* characteristic of zinc and of chlorides. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, or sulphates. *Arsenic limit* 5 parts per million. 0.25 gramme, tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

When pure, it is wholly soluble in water, alcohol, and ether, but as prepared by the U. S. formula it contains some oxychloride,

which is left undissolved by water. According to Lassaigne, commercial zinc chloride sometimes contains as much as 12 per cent. of zinc arsenate, which, being insoluble in solution of zinc chloride, will be left undissolved when the chloride is treated with water. By filtration, therefore, it may be entirely separated. It yields with ammonium and potassium hydroxide a white precipitate, soluble in those reagents when added in excess. It tends to form basic insoluble compounds, the so-called *oxychlorides,* of which Sorel's mass, $Zn\begin{cases}OH\\Cl\end{cases}$, is an example.

These are used for cements and as a filling for teeth. The potassium and sodium carbonates also throw down white precipitates, which are not dissolved by an excess of the precipitants. Zinc chloride has a strong tendency to combine with organic bases, forming crystallizable compounds, as with strychnine, morphine, quinine, cinchonine, etc., in this respect resembling certain other metallic chlorides, as platinum, palladium, gold, and mercury chlorides. (*J. P. C.*, 4e sér., iii, 56.) When exposed to heat, zinc chloride first melts and then sublimes. It has been obtained in small deliquescent octahedrons of the formula $ZnCl_2 + H_2O$, by evaporating its hydrochloric acid solution to a syrup, and then adding a little concentrated hydrochloric acid. It consists of one atom of zinc and two of chlorine.

Uses.—Zinc chloride has been used internally in *scrofula, epilepsy, chorea,* and other nervous diseases, but is of little or no value. Its chief use has been as an escharotic in *cancerous affections.* As a caustic it has the advantage of not causing constitutional disorder from absorption. Canquoin prepared zinc chloride as an escharotic by thoroughly and quickly mixing it with wheat flour and water into a paste of four different strengths, containing severally an ounce of the chloride incorporated with two, three, four, and five ounces of flour, fifteen drops of water being added for every ounce of flour, or sufficient to form the paste. According to the French Codex, *Caustique au Chlorure de Zinc* (*Canquoin's Paste*) is prepared by dissolving 8 parts of zinc chloride in 1 part of cold water and incorporating a mixture of 6 parts of flour with 2 parts of zinc oxide.

P. Carles states that the official paste is too hygroscopic; he triturates in a mortar 10 grammes of fused zinc chloride with 2 grammes of 60 per cent. alcohol, and incorporates, with constant trituration, 15 grammes of wheat flour. This mass may be formed into cylinders of suitable size, and when once dry is but little affected by atmospheric humidity. (*L'Union Pharm.*)

It is applied in cakes from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness and strength of the paste, the length of the application, and the nature of the part acted on. Canquoin's strongest paste is applied to lardaceous and fibro-cartilaginous structures; the second, to *carcinomatous tumors,* and very painful *cancers* which have not much thickness; and the third, to *cancerous affections* in persons who have a dread of the use of the knife. These preparations, applied to the skin denuded of its cuticle by means of a blister, excite in a few minutes a sensation of heat, and afterwards violent burning pain. The eschar, which is white, thick, and very hard, falls off, with the aid of an emollient poultice, between the eighth and twelfth days. In all cases the caustic is to be reapplied, after the falling off of the eschar, until the whole morbid structure is destroyed. When the skin is unbroken, it is usual to destroy not merely the cuticle, but the true skin also, by means of acid mercuric nitrate, to the extent to which the chloride is desired to operate. This is applied spread on lint, and the dressing is covered with a portion of cotton wadding, to absorb any discharge and to preserve a uniform temperature. The surrounding skin should be protected from the caustic by a thickly-spread dressing of simple cerate.

Felix's Caustic Paste (*L. L.*, vol. ii, 1887) is made according to the following formula: Starch, 37 grammes; Wheat Flour, 112 grammes; Mercuric Chloride, 1 gramme; Dry Zinc Chloride, 110 grammes; pure Iodol, 10 grammes; Croton Chloral, 10 grammes; Camphor Bromide 10 grammes; Crystallized Carbolic Acid, 10 grammes; Distilled Water, sufficient to form a stiff homogeneous paste. The hand should be wetted when applying it. The paste is allowed to remain on from six to twenty-four hours, according to the amount of eschar it is desired to form.

Instead of flour, Alex. Ure of Glasgow, mixes the chloride with pure anhydrous calcium sulphate in impalpable powder. He states that this has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Cock of Guy's Hospital, has imitated this mode of preparing the chloride, so as to form a caustic which may be limited in its action and does not run. It may be prepared as a caustic seton by thickly covering a waxed cotton wick with Canquoin's caustic paste, and then rolling it out in the form of a cylinder, according to the plan of Ancrenis of Lyons. A thread is wound spirally around the cylinder to give it firmness.

In overdoses, zinc chloride acts as a corrosive poison, producing burning pain in the gullet and stomach, nausea and vomiting, cold sweats, depression of the pulse, and cramps of the legs. The antidotes are weak alkalies, or their carbonates, and, if these are not immediately at hand, soap. Zinc chloride is not used internally.

Zinc chloride is a useful disinfectant, being inexpensive and comparatively non-poisonous.

ZINCI OLEOSTEARAS. Br.

ZINC OLEOSTEARATE

(zĭn'cī ō-lē-ō-stē'ą-răs)

"Hard Soap, 200 *grammes;* Curd Soap, 100 *grammes;* Zinc Sulphate, 100 *grammes;* Distilled Water, *a sufficient quantity.* Dissolve the Soaps in one thousand five hundred millilitres of the Distilled Water by the aid of heat; add to the solution the Zinc Sulphate previously dissolved in two hundred millilitres of the Distilled Water. Collect the precipitate, wash it with Distilled Water until the washings are free from sulphates, dry it, and reduce it to a fine powder." *Br.*

It is officially described as "a white amorphous powder. Odor faint, resembling that of fat. Insoluble in *water,* in *alcohol* (90 per cent.), and in *ether.* Ash about 13 per cent. The ash, dissolved in *hydrochloric acid* and the solution neutralised, yields the *reactions* characteristic of zinc. When 0.5 gramme is heated with 0.5 millilitre of *hydrochloric acid* diluted with 0.5 millilitre of *water,* a mixture of fatty acids is liberated and floats on the surface of the aqueous liquid; this aqueous liquid, filtered, neutralised with *solution of ammonia,* treated with excess of *solution of ammonium hydrosulphide,* again filtered, evaporated to dryness, and the product gently ignited, leaves no appreciable residue (absence of fixed alkalies and of alkaline earths)." *Br.*

Uses.—Zinc oleostearate is used for the same purposes as zinc stearate.

ZINCI OXIDUM. U. S., Br.

ZINC OXIDE Zinc. Oxid.

(zĭn'cī ŏx'ĭ-dŭm)

"It contains, when freshly ignited, not less than 99 per cent. of ZnO (81.37)." *U. S.*
"Zinc Oxide, ZnO, may be obtained from metallic zinc by combustion in air." *Br.*

Flores Zinci; Oxydum Zincicum; Oxyde Zinc par voie sèche, Fleurs de Zinc, *Fr. Cod.;* Zincum Oxydatum, *P. G.;* Philosophenwolle, Zinkblumen, Zinkoxyd, *G.;* Oxido zincico, *Sp.*

Preparation.—The British Pharm., 1885, and the U. S. P., 1870, prepared the zinc oxide from the carbonate already formed. By referring to the article on Precipitated Zinc Carbonate, it will be found that it is obtained in the process from zinc sulphate, by the decomposing influence of sodium carbonate. Other methods of obtaining the zinc carbonate are by the mutual decomposition of the sodium chloride and carbonate and the ammonium sulphate and carbonate, but the former official plan is preferred. Lefort found it to furnish a carbonate which is washed with facility and is convertible by calcination into a pure oxide, readily reduced to an impalpable and very light powder. (*J. P. C.,* 3e sér., xi, 329.) It is, besides, more economical. The zinc carbonate, in whatever way obtained, is exposed to heat to drive off the carbon dioxide and water, in order to obtain the oxide. According to Mohr, a full red heat is not necessary, a temperature between 280° and 300° C. (536° and 572° F.) being sufficient. It is probable that an unnecessarily high heat injures the oxide as a therapeutic agent.

"Take of Precipitated Carbonate of Zinc *twelve troyounces.* Expose it, in a shallow vessel, to a low red heat until the water and carbonic acid are wholly expelled." *U. S.,* 1870.

Zinc oxide may be obtained by the combustion of the metal. Zinc melts at 433° C. (811.4° F.), and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. One form of apparatus for the production of the oxide, as practically carried on, consists of a large muffle, heated to redness in a suitable furnace, and supplied with zinc from time to time as the combustion proceeds. The necessary draught of air is conveyed from the muffle by a tube passing through the top of the furnace and terminating in a vessel of water, in which the portion of oxide carried up by the current is retained. The resulting oxide is freed from particles of metallic zinc by being passed through a sieve. Zinc oxide has been very largely produced from calamine by the so-called "furnace and bag" process, at Bethlehem, Pa., by the Lehigh Zinc Company. The process is as follows: The ore is first ground fine by a stone crusher, and then carefully mixed with coal known as "buckwheat," next in grade to "pea." It is then transferred to the furnaces, of which there are fifty-four, with 1390 feet of grate-surface. Within these the mixed coal and ore are reduced by the direct action of heat and the cold blast upon a furnace bed having a multiplicity of small holes, each producing the reducing flame of the blow-pipe. The zinc oxide rises, and passes through a huge combustion flue to a large circular tower, 50 feet high, in which the oxide and ashes separate. The ashes being heavier than the oxide, the velocity of the fans which impel the product forward lifts the oxide to the top, and the ashes drop to the bottom. The oxide is forced onward through a cooling-room, size 80 by 40 feet, and heated to from 204.8° to 371.1° C. (400.5°–700° F.). Thence the oxide is blown through large flues into the "bag" room. This is in a large building, devoid of furniture, except bags of muslin, 45 feet long, in which the oxide is deposited. It is now very white, and, after being kiln-dried and bolted, is by heavy pressure reduced in bulk and barrelled, ready for shipment. The production direct from ore is available only when the latter is free from cadmium, as otherwise the zinc oxide would be contaminated with cadmium oxide.

Properties.—The official zinc oxide is described in the U. S. Pharmacopœia as "a very fine, amorphous, white or yellowish-white pow-

der, free from gritty particles, without odor or taste; it gradually absorbs carbon dioxide from the air. Zinc Oxide is insoluble in water or in alcohol; it dissolves without effervescence in dilute acids, also in ammonia water and in ammonium carbonate T.S. When strongly heated, it assumes a yellow color which disappears on cooling. For making the following tests for identity, digest 1.3 Gm. of Zinc Oxide, with occasional agitation, in a mixture of 10 mils of diluted hydrochloric acid and 10 mils of distilled water until the solution is saturated, then remove the undissolved Zinc Oxide by filtration. In portions of this filtrate a white, gelatinous precipitate is produced by potassium ferrocyanide T.S., and a white precipitate by ammonium sulphide T.S. Ten mils of a solution of Zinc Oxide (1 in 50), made with the aid of a slight excess of hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). Mix 1 Gm. of Zinc Oxide in a flask with 10 mils of boiling distilled water and add 2 drops of phenolphthalein T.S.; not more than 1 mil of tenth-normal hydrochloric acid V.S. is required to discharge any red color that may be produced (*alkali*).

Assay.—"Digest about 1.5 Gm. of freshly ignited Zinc Oxide, accurately weighed, with 50 mils of normal sulphuric acid V.S. until solution is complete. Then titrate the excess of sulphuric acid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 99 per cent. of ZnO.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.040685 Gm. of ZnO. Each gramme of freshly ignited Zinc Oxide corresponds to not less than 24.3 mils of normal sulphuric acid V.S." *U. S.*

"A soft, white or nearly white, amorphous powder, becoming pale yellow when heated. No odor or taste. Yields the *reactions* characteristic of zinc. Soluble in *diluted hydrochloric acid* without the separation of any black particles. Yields no characteristic *reactions* for copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, and only slight *reactions* for lead and carbonates. *Arsenic limit* 10 parts per million. 0.2 gramme, dissolved in *diluted sulphuric acid*, and tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

As obtained by combustion, it is perfectly white. It dissolves in solution of potassium and sodium hydroxides, but not in their carbonates. Being anhydrous, it is insoluble in ammonia, but the impure oxide found in commerce, being generally hydrated, is soluble in that alkali. At a low white heat it fuses, and at full whiteness sublimes. When prepared by combustion it was formerly called *pompholix, nihil album, lana philosophica*, and *flowers of zinc*. Prepared by the old official process—namely, by precipitating zinc sulphate with ammonia—it contains the subsulphate, which may be detected by dissolving the oxide in nitric acid and adding barium nitrate T. S. which produces a white precipitate if a sulphate is present. Sometimes it is obtained by precipitating zinc chloride with ammonia, in which case the oxide contains subchloride, easily detected by silver nitrate. If it contains white lead or chalk, it will not be entirely soluble in diluted sulphuric acid, but an insoluble lead or calcium sulphate will be left. If iron be present, brownish-red flocks of ferric oxide will remain undissolved when the hydrochloric acid solution of the zinc oxide is treated with ammonia in excess.

The powder sold in commerce as zinc oxide is often very impure. Sometimes the carbonate is substituted for it, showing that the exposure to a red heat has been omitted. In this case the preparation will effervesce with acids. Some samples contain a large proportion of subsulphate, showing that the discarded but productive process of precipitating the solution of zinc sulphate by ammonia has been employed. Again, other samples contain oxychloride, which can be detected by adding silver nitrate T. S. to the nitric acid solution of the oxide. These impure oxides are pointed out by Redwood, of London, as occurring in the English market, and no doubt are sold in the United States. A sample of commercial zinc oxide is noticed in *N. R.*, Aug., 1878, which proved to be powdered gypsum. Unfortunately, a white oxide is preferred by purchasers, though whiteness is generally a sign of impurity; the yellowish-white official oxide should be exclusively used by pharmacists. There has been reported in Swiss commerce an unusual form of zinc oxide, which is in light loose powder that produces a lumpy ointment and which, when rubbed with two-thirds its weight of olive oil, does not form a paste as do the ordinary oxides, but remains as a dry powder.

Uses.—Zinc oxide has been used as an antispasmodic in *chorea, epilepsy,* and *whooping-cough,* but is probably of little value as a systemic remedy. It is also sometimes employed for its astringent and sedative properties in *diarrhea.* Its most important use, however, is as an application to excoriated surfaces and in various *skin diseases.* It owes its popularity to a combination of four qualities: it is non-toxic, protective, mildly astringent and probably antiseptic. It may be applied as a dusting powder—usually in conjunction with talcum—suspended in aqueous mixtures or in the form of ointment. (See *Unguentum Zinci Oxidi.*) It has also been used in *gonorrhea.* As a cosmetic it has the great advantage over the preparations of lead of not being poisonous.

Zinc oxide, prepared by combustion, called commercial zinc oxide, is extensively used in painting as a substitute for white lead, over which it has the advantage of not being discolored by hydrogen sulphide. It is stated that it has greater covering power as a color than white lead, 10 parts being equal to 13 of white lead. It is, however, dearer, so that the pure oxide has not replaced white lead. This form of oxide, even though pure, is often unsuited for medical uses, because of lack of

smoothness and the presence of gritty particles. There is an English preparation known as *Griffith's zinc white*, or *lithophone*, made by precipitating zinc sulphate by barium sulphide; it is, therefore, a mixture of zinc sulphide and barium sulphate. If this be roasted in a current of superheated steam the zinc sulphide will be converted into zinc oxide. This process has been patented in Germany by Meissner. (Wagner's *Chem. Technol.*, 11th ed., p. 159.)

Dose, two to five grains (0.13–0.32 Gm.), preferably in pill form.

ZINCI PHENOLSULPHONAS. U. S.

ZINC PHENOLSULPHONATE Zinc. Phenolsulph. [Zinc Sulphocarbolate]

(zĭn'cī phē-nŏl-sŭl'phŏ-năs)

"It contains not less than 73.7 per cent. nor more than 77.4 per cent. of anhydrous zinc phenolsulphonate, corresponding to not less than 99.5 per cent. of the crystallized salt [$(C_6H_5O.SO_3)_2Zn + 8H_2O = 555.72$]. Preserve it in small, well-closed containers." *U. S.*

Zinci Sulphocarbolas, *Br.* 1898; Zincum Sulphophenolicum; Zinc Paraphenolsulphonate; Sulphophénate de Zinc, *Fr.*; Phenolsulfosaures Zink, Sulfokarbolsaures Zink, *G.*

Properties.—It is officially described as in "colorless, transparent, rhombic prisms or tabular crystals or in granular form; odorless, and having an astringent, metallic taste. When exposed to the air the salt effloresces, and upon exposure to light and air may become slightly pink. One Gm. of Zinc Phenolsulphonate dissolves in 1.6 mils of water, and in 1.8 mils of alcohol at 25° C. (77° F.); also in 0.4 mil of boiling water. Its aqueous solution (1 in 10) is acid to litmus. When heated to 125° C. (257° F.), the salt loses all of its water of crystallization. At a higher temperature it chars, emitting inflammable vapors having the odor of phenol, and finally leaves an incombustible residue. An aqueous solution of the salt (1 in 20) yields a white, gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S. Ammonium carbonate T.S., when added in small portions to an aqueous solution of the salt (1 in 20), produces a white precipitate which redissolves completely upon the addition of an excess of the reagent. A dilute solution of the salt (1 in 100) is colored pale violet by ferric chloride T.S. The addition of a few drops of barium chloride T.S. to 10 mils of an aqueous solution of the salt (1 in 20), previously acidulated with 3 drops of hydrochloric acid, produces not more than a slight turbidity (*sulphate*). Ten mils of an aqueous solution of the salt (1 in 50), to which 1 mil of diluted hydrochloric acid has been added, does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

Assay.—"Dissolve about 1 Gm. of Zinc Phenolsulphonate, accurately weighed, in 100 mils of distilled water and proceed as directed in the assay under *Zinci Acetas*. The amount of zinc oxide obtained corresponds to not less than 73.7 per cent. nor more than 77.4 per cent. of $Zn(C_6H_5O_4S_2)_2$.

"Each gramme of Zinc Phenolsulphonate corresponds to not less than 0.146 Gm. nor more than 0.153 Gm. of ZnO.

"Zinc Phenolsulphonate may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

Uses.—Zinc phenolsulphonate has been employed as an antiseptic and astringent application to indolent or foul *ulcers*, and in subacute inflammations of the mucous membrane. The solutions used may be a little stronger than those of zinc sulphate employed for similar purposes. It has also been used as an intestinal antiseptic.

Dose, one to three grains (0.065–0.2 Gm.).

ZINCI STEARAS. U. S.

ZINC STEARATE Zinc. Stear.

(zĭn'cī stē'ăr-ăs)

"A compound of zinc with stearic acid and small, but variable proportions of palmitic acid, containing an amount of zinc corresponding to not less than 13 per cent. nor more than 15.5 per cent. of ZnO." *U. S.*

Stéarate de Zinc, *Fr.*; Zinkstearat, Stearinsaures Zinkoxyd, Talgsaures Zinkoxyd, *G.*

(See *Zinci Oleostearas*, Br., page 1211.)

Zinc stearate differs from the oleate of zinc of the U. S. P., 1890; the latter was of a soft ointment-like solid. It may be made by mixing a solution of sodium stearate with one of zinc acetate, at a temperature of 50° C. (122° F.), washing, and then drying the precipitate. For a process for zinc oleostearate by F. E. Niece in which he uses oleic and stearic acids and solution of zinc acetate, see *Proc. Penna. Pharm. Assoc.*, 1902, 135.

Properties.—It is officially described as "a fine, white, bulky powder, tasteless and having a faint, characteristic odor. Zinc Stearate is insoluble in water, alcohol or ether. The salt is neutral to moistened litmus paper. When heated, the salt fuses. At a higher temperature it is decomposed, giving off inflammable vapors and the odor of burning fat, and finally leaves a residue consisting chiefly of zinc oxide. Heat 1 Gm. of Zinc Stearate with a mixture of 25 mils of distilled water and 5 mils of hydrochloric acid; stearic acid is liberated and floats as an oily layer on the surface of the liquid. Boil 1 Gm. of Zinc Stearate with 25 mils of distilled water and 5 mils of hydrochloric acid, filter while hot and wash the filter with 25 mils of

hot water. Render the filtrate alkaline with ammonia water, warm it to 80° C. (176° F.), and add ammonium sulphide T.S. in excess, filter, evaporate the filtrate to dryness, and ignite the residue. Dissolve this residue in 10 mils of hot distilled water, filter, again evaporate, ignite, and weigh; not more than 1 per cent. of residue remains (*alkalies and alkali earths*). The insoluble residue of fatty acids obtained in the preceding test, when well washed, melts at a temperature not below 56° C. (132.8° F.).

Assay.—"Boil about 1 Gm. of Zinc Stearate, accurately weighed, with 50 mils of tenth-normal sulphuric acid V.S. for ten minutes and cool. Then titrate the excess of sulphuric acid with tenth-normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 13 per cent. nor more than 15.5 per cent. of ZnO.

"Each mil of tenth-normal sulphuric acid V.S. used corresponds to 0.0040685 Gm. of ZnO. Each gramme of Zinc Stearate corresponds to not less than 32 mils nor more than 38.1 mils of tenth-normal sulphuric acid V.S." *U. S.*

Uses.—Zinc stearate is employed in *eczema, acne* and other cutaneous diseases, in the form of powder, or made into an ointment.

Off. Prep.—Unguentum Zinci Stearatis, *N. F.*

ZINCI SULPHAS. U. S., Br.

ZINC SULPHATE Zinc. Sulph.

(zĭn'cī sŭl'phăs)

"It contains not less than 55.86 per cent. nor more than 58.65 per cent. of anhydrous zinc sulphate, corresponding to not less than 99.5 per cent. of the crystallized salt [$ZnSO_4 + 7H_2O = 287.55$]. Preserve it in well-closed containers." *U. S.* "Zinc Sulphate, $ZnSO_4$, $7H_2O$, may be obtained by the interaction of diluted sulphuric acid and zinc." *Br.*

Sulfas Zincicus, Vitriolum Album; White Vitriol; Sulfate de Zinc officinal, *Fr. Cod.;* Zincum Sulfuricum, *P. G.;* Zinksulfat, Schwefelsaures Zinkoxyd, Weisser Vitriol, Galitzenstein, *G.;* Solfato di zinco, *It.;* Sulfato zincico, *Sp.*

The Pharmacopœias no longer give detailed processes for preparing this salt.

Strong sulphuric acid is but slightly acted upon by zinc, some hydrogen sulphide being evolved by the reduction of the acid; but when it is *diluted,* the acid is instantly decomposed, and, while hydrogen escapes with rapid effervescence, it is replaced by the zinc with the production of zinc sulphate. From this it will be perceived that *hydrogen* is a collateral product of the process. The proportion of the zinc to the strong acid in the process is as 4 to 5.53. The molecular weights give the ratio of 4 to 6 almost exactly—which indicates that the metal is somewhat in excess. If the materials are mixed at once, without any precaution, the effervescence of hydrogen is apt to be excessive, and to cause the overflowing of the liquid. This may be avoided by commencing the solution of zinc with a very dilute acid, which, as the action slackens, is made by degrees stronger and stronger by the addition, at intervals, of small portions of fresh acid. As the zinc of commerce generally contains iron, this would contaminate the product, unless precautions were taken to prevent it. Hence the addition of chlorine, which reacts with ferrous sulphate to form ferric sulphate and ferric chloride, which, upon the addition of zinc carbonate, yield sulphuric acid and chlorine to the zinc, ferric oxide being deposited and carbon dioxide set free. The former is separated by filtration, the latter escapes during the evaporation, the additional zinc sulphate crystallizes with that first formed, and the zinc chloride remains in the mother waters.

Preparation on the Large Scale.—Impure zinc sulphate, as it occurs in commerce, is called *white vitriol.* It is manufactured by roasting *blende* (native zinc sulphide) in a reverberatory furnace. This mineral, besides zinc sulphide, contains small quantities of iron, copper, and lead sulphides, and by roasting is converted, in consequence of the oxidation of its constituents, into zinc sulphate, mixed with iron, copper, and lead sulphate. The roasted matter is then lixiviated, and the solution obtained, after having been allowed to settle, is concentrated by evaporation, so that, on cooling, it may concrete into a white crystalline mass. In this state it always contains ferrous sulphate, and sometimes a small proportion of copper sulphate. It may be purified from these metals by dissolving it in water and boiling the solution with zinc oxide, which converts the iron and copper sulphates into zinc sulphate and the respective hydroxides of iron and copper. The purified solution is then decanted or filtered, and, after due evaporation, allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under the impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on iron. F. Stolba recommends a process which has been used successfully for the purification of zinc sulphate by the use of zinc carbonate and zinc permanganate.

Properties.—Zinc sulphate is in "colorless, transparent, rhombic crystals, or as a granular, crystalline powder, without odor, and having an astringent, metallic taste. It is efflorescent in dry air. One Gm. of Zinc Sulphate dissolves in 0.6 mil of water, and in 2.5 mils of glycerin at 25° C. (77° F.); insoluble in alcohol. Its aqueous solution (1 in 10) is acid to litmus. When rapidly heated, the salt melts. When strongly ignited it is partly decomposed, losing both water and sulphuric acid. An aqueous solution of the salt (1 in 20) yields a white, gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S. and with barium chloride T.S. An aqueous solution of the salt (1 in 10) yields with ammonium carbonate T.S. a white precipitate, which redissolves completely in an excess of the reagent. Ten mils of an aqueous solution of Zinc Sulphate (1 in 50), after being

acidulated with 1 mil of diluted hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1). An aqueous solution of Zinc Sulphate (1 in 20) is not colored pink by methyl orange T.S. (*free acid*). Add 2 drops of nitric acid to a solution of 1 Gm. of Zinc Sulphate in 20 mils of distilled water, follow with 0.2 mil of tenth-normal silver nitrate V.S. and filter the mixture. The subsequent addition of a few drops of tenth-normal silver nitrate V.S. to the filtrate produces no cloudiness or opalescence (*chloride*). Dissolve 1 Gm. of Zinc Sulphate in 50 mils of distilled water, precipitate the zinc completely with ammonium sulphide T.S., filter, evaporate the filtrate to dryness, and ignite; not more than 0.5 per cent. of residue remains (*alkali and alkali earth salts*).

Assay.—"Dissolve about 1 Gm. of Zinc Sulphate, accurately weighed, in 100 mils of distilled water and estimate the salt as zinc oxide by the method given in the assay under *Zinci Acetas*. The salt yields an amount of zinc oxide corresponding to not less than 55.86 per cent. nor more than 58.65 per cent. of $ZnSO_4$.

"Each gramme of Zinc Sulphate corresponds to not less than 0.2815 Gm. nor more than 0.2955 Gm. of ZnO. Zinc Sulphate may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"Colorless, transparent, prismatic crystals. Taste metallic, styptic. Soluble in less than 1 part of *water*. Yields the *reactions* characteristic of zinc and of sulphates. Yields no characteristic *reactions* for lead, copper, cadmium, aluminium, calcium, magnesium, sodium, potassium, ammonium, or acetates, and not more than the slightest *reactions* for iron or chlorides. *Arsenic limit* 5 parts per million. When 0.5 gramme is dissolved in *water*, excess of *solution of ammonia* added, and the mixture allowed to stand, any precipitate that is obtained being filtered off and dissolved in *diluted nitric acid*, then this acid solution, diluted with *water* to about 15 millilitres and heated to boiling, does not acquire more than a faint pink coloration on the addition of 1 millilitre of *N/10 solution of silver nitrate* and 10 millilitres of an aqueous solution (1 in 10) of *ammonium persulphate* (limit of manganese)." *Br.*

Zinc sulphate is incompatible with alkalies and alkaline carbonates, sulphides, lime water, the soluble lead salts, and astringent infusions.

Composition.—Crystallized zinc sulphate consists of one sulphuric acid group, SO_4, one atom of zinc, and seven molecules of water. The *white vitriol* of commerce contains but three molecules of water.

The impure commercial variety of zinc sulphate is in the form of irregular white masses having some resemblance to lump sugar. The lumps usually exhibit, here and there on the surface, yellow stains, produced by ferric compounds. It is less soluble than the pure salt, on account of its containing less water by crystallization.

Uses.—Internally, zinc sulphate is, at present, employed only for its emetic action. Because of the promptness and certainty of its effect and its comparative freedom from danger it is one of the most valuable vomitants we possess in various *poisonings*. Externally, it is used as an active astringent, mild caustic, or disinfectant. Its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in *fluor albus* and *gonorrhea*, and as a collyrium in *ophthalmia*, also as a stimulant application to *ulcers* both of the mucous membrane and of the skin. Simpson, of Edinburgh, employed dried zinc sulphate in the form of powder, paste, or ointment, as a powerful, rapid, manageable, and safe caustic in indurated inflammatory ulcers of the cervix uteri, in *lupus*, in *ulcerous forms of skin diseases*, and in removing *urethral caruncles, condylomata, warty excrescences*, etc. The dried salt should be finely levigated. The caustic paste is made by incorporating an ounce of the powder with a drachm of glycerin; and the caustic ointment, by thoroughly mixing the same quantity of the powder with two drachms of lard.

Zinc sulphate, in an overdose, acts as an irritant poison. Besides vomiting and incessant retching, it produces anxiety, distressing restlessness, and extreme prostration. Few cases are on record of fatal poisoning by this salt, the patient being generally relieved by its prompt expulsion in vomiting. Death is said to have been caused, however, by an ounce and a half. The treatment consists in the free administration of bland drinks, the use of opium to allay irritation, and the employment of the usual antiphlogistic remedies should symptoms of inflammation arise.

Dose, from one-fourth to one-half grain (0.016–0.032 Gm.); as an emetic, from ten to thirty grains (0.65–2.0 Gm.). When used as a collyrium, an injection, or a gargle, or as a wash for indolent ulcers, from one to three grains (0.065–0.2 Gm.) or more may be dissolved in a fluidounce (30 mils) of water. For medicinal purposes the crystallized salt only should be used.

ZINCI VALERAS. U. S. (Br.)

ZINC VALERATE Zinc. Valer.

(zĭn'cī văl'ę-rās).

"It contains not less than 99 per cent. of the crystallized salt [$Zn(C_5H_9O_2)_2 + 2H_2O = 303.55$]. Preserve it in small, well-closed containers." *U. S.* "Zinc Valerate, $Zn(C_5H_9O_2)_2$, $2H_2O$, may be obtained by saturating iso-valerianic acid with zinc carbonate, or by the interaction of zinc sulphate and sodium iso-valerianate." *Br.*

Zinci Valerianas, *Br.;* Zincum Valerianicum; Valerianas Zincicus; Valérianate de Zinc, *Fr. Cod.;* Valérate de Zinc, *Fr.;* Zincvalerianat, Baldriansaures Zinkoxyd, *G.;* Valerianato zincico, *Sp.*

The present Pharmacopœias do not give a method for preparing this salt; for former formulas, see *U. S. Dispensatory,* 19th edition, p. 1359.

Properties.—"Zinc Valerate occurs as white, pearly scales, or as a white powder having the odor of valeric acid, and a sweetish, astringent, and metallic taste. On exposure to the air, it slowly loses valeric acid and becomes partially insoluble in water. One Gm. of Zinc Valerate dissolves in 70 mils of water at 25° C. (77° F.), usually leaving an insoluble residue of basic salt; soluble in 22 mils of alcohol at 25° C. (77° F.). Its aqueous solution (1 in 100) is acid to litmus. When gently heated, the salt melts. At a higher temperature it is decomposed, giving off inflammable vapors, and finally leaving a residue consisting chiefly of zinc oxide. Dissolve 0.5 Gm. of Zinc Valerate in a mixture of 0.5 mil of hydrochloric acid and 9 mils of distilled water; the valeric (isovaleric) acid is liberated and floats as an oily layer on the surface of the liquid. Filter the mixture just prepared through a small, wetted filter; the clear filtrate diluted with distilled water to 25 mils does not respond to the Test for heavy metals (see Part III, Test No. 3). Heat 0.5 Gm. of Zinc Valerate with a mixture of 7.5 mils of distilled water and 5 mils of diluted sulphuric acid and filter; 5 mils of the filtrate meets the requirements for the Test for arsenic (see Part III, Test No. 1). Zinc Valerate dissolves in ammonium carbonate T.S. without leaving a residue. Triturate 0.5 Gm. of Zinc Valerate with 3 mils of distilled water and 0.2 mil of ferric chloride T.S., and filter; the filtrate does not show a red color (*acetate*). Add a concentrated, aqueous solution of copper acetate to a concentrated aqueous solution of Zinc Valerate; the mixture remains perfectly clear (*butyrate*).

Assay.—"Dissolve about 1 Gm. of Zinc Valerate, accurately weighed, in 100 mils of distilled water, with the aid of a few drops of hydrochloric acid, if necessary, and estimate the zinc as zinc oxide by the method given in the assay under *Zinci Acetas.* The salt yields an amount of zinc oxide corresponding to not less than 99 per cent. of $Zn(C_5H_9O_2)_2 + 2H_2O$.

"Each gramme of Zinc Valerate corresponds to not less than 0.265 Gm. of ZnO. Zinc Valerate may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"White, pearly, tabular crystals. Disagreeable odor; taste metallic. Very slightly soluble in cold *water,* or in *ether;* soluble in hot *water,* and in *alcohol* (90 per cent.). Yields, when heated to redness, after moistening with a small quantity of *nitric acid,* not less than 26 or more than 27 per cent. of zinc oxide. Yields no characteristic *reactions* for lead, copper, cadmium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, acetates, or carbonates, and not more than the slightest *reactions* for chlorides or sulphates. *Arsenic limit* 5 parts per million. When heated in a retort with *diluted sulphuric acid* it yields a distillate which, when added to *a solution of copper acetate,* does not immediately become turbid or opalescent, but forms after a short time oily drops, which gradually pass into a bluish-white crystalline deposit (absence of butyrates). 0.2 gramme of the zinc oxide obtained on incineration, dissolved in *diluted sulphuric acid,* and tested as described under 'Zinci Sulphas,' yields a solution with not more than a faint pink coloration (limit of manganese)." *Br.*

The salt, as obtained by the British, 1885, and U. S. P., 1870, formulas, contained one molecule of water; but when formed by saturating zinc carbonate, made into a paste with water, with valeric acid, it contains six molecules of water, and when dried at 50° C. (122° F.), perfectly resembles the official salt. (Wittstein.) Other authorities (Flückiger, *Pharm. Chem.,* and Roscoe and Schorlemmer's *Chem.,* vol. iii, Part I) gave the formula of the stable crystallized salt as $Zn(C_5H_9O_2)_2 + 2H_2O$. Zinc acetate impregnated with oil of valerian has been substituted for this salt; but at present, from the relative costliness of the oil, there is no inducement to this fraud. Zinc butyrate has been sold in Paris for the valerate, and is so like it as not to be distinguished by its physical properties. The two salts, however, may be differentiated by adding a concentrated solution of the acid of the suspected salt obtained by distillation with sulphuric acid, to a concentrated solution of copper acetate. If the acid be the butyric, its addition to the solution of the acetate will disturb the transparency of the latter, by the formation of a bluish-white precipitate; if it be the valeric, no change will be produced. (Larocque and Huraut, *J. P. C.,* 3e sér., ix, 430.)

Uses.—This salt has been used in *neuralgia, epilepsy,* and other nervous diseases, but is probably without therapeutic value. It has also been suggested for *diabetes insipidus.*

Dose, one to two grains (0.065–0.13 Gm.), repeated several times a day, and given in the form of pill.

Off. Prep.—Elixir Zinci Valeratis, *N. F.*

ZINCUM. U. S.

ZINC Zinc.

(zĭn'cŭm)

"It contains not less than 99 per cent. of Zn (65.37)." *U. S.*

Spelтrum; Zinc pur. *Fr. Cod.;* Speltre, Zinc, *Fr.;* Zink, *G.;* Zinco, *It.;* Zinc, *Sp.*

Zinc occurs native in two principal states, as a sulphide, called *blende,* and as a carbonate or silicate, to which the name of *calamine* is applied indiscriminately, although the name belongs properly only to the latter. In this country there are two additional ores that are worked

for zinc. Both occur at Franklin and Mine Hill, New Jersey, and are characteristic of those localities. They are the native oxide, called *red oxide* or *zincite*, and a mixture of zinc oxide with manganese and iron oxide, known as *franklinite*. Zinc has been detected in the vegetable kingdom in a peculiar violet, *Viola calamina*, growing on the calamine hills of Rhenish Prussia. It is largely produced in Belgium, Germany, and this country, the chief American localities being the southwestern section of Missouri, together with the neighboring counties of Kansas, the New Jersey localities before mentioned, Lehigh County, Pennsylvania, Virginia, Wisconsin and Montana. The metal is extracted generally from blende or calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders placed horizontally over a furnace. When the reduction of the zinc commences, iron receivers are adapted to the opening of the cylinder to condense the volatilized metal. The metal is then melted and run into moulds, and forms *spelter*, or the zinc of commerce. In this state it contains iron, and traces of lead, cadmium, arsenic, copper, sulphur, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom and open at both ends, its upper extremity reaching a little more than half-way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and, passing down the tube by a descending distillation, condenses in the water below. In the arts zinc is purified sufficiently for commercial purposes without volatilization.

The production of spelter in the United States for the year 1914 amounted to 353,049 tons, and for 1915 to 489,519 tons, which is double the output in 1910. Previous to the European war Belgium produced about 200,000 tons a year and France about 64,000 tons; these are not, at present, available.

Properties.—Zinc has a bluish-white color, a peculiar taste, and a perceptible odor when rubbed. Its texture is laminated, and its fracture crystalline. Its malleability and ductility are not very great. When perfectly pure, it may be reduced to thin leaves at ordinary temperatures; but the zinc of commerce requires to be heated to a temperature between 100° and 148.8° C. (212° and 300° F.) to render it sufficiently malleable to be rolled into sheets. The softness of zinc is peculiar, as shown by the circumstance that it clogs the file when the attempt is made to reduce it to filings; and hence to have it in the divided form it is necessary to melt it, and triturate it at the moment of solidification. Subject to heat it fuses at 398° C. (748.4° F.). According to A. von Riemsdyk, it volatilizes to some extent before fusion at a temperature of 268.3° C. (515° F.). (*A. J. P.*, 1869, p. 424.) At full redness it boils, and in close vessels may be distilled over; but in open vessels it takes fire, and burns with a dazzling white flame, giving off dense white fumes. It dissolves in most of the acids with disengagement of hydrogen, and precipitates all the metals either in the metallic state or in that of oxide. It forms but one oxide (a monoxide) and but one sulphide. The monoxide is official, and has been described under another head. (See *Zinci Oxidum.*)

Zincum Granulatum, Br., 1885. *Granulated Zinc.*—"Take of Zinc of commerce *one pound.* Heat it in an earthen crucible, and immediately the metal is fused remove the crucible from the fire and pour the fluid in a thin stream into a vessel containing about two gallons of cold water. Drain off the water and dry the granulated zinc." *Br.*, 1885.

The official zinc is described as "a bluish-white metal, showing a crystalline fracture. It occurs in the form of thin sheets, or in irregular, granulated pieces, or moulded into thin pencils, or in powder, and having a specific gravity ranging from 6.9 when it is cast to 7.2 after it is rolled. It is dissolved by diluted sulphuric or hydrochloric acid with the evolution of hydrogen, usually leaving some insoluble residue. When heated above 100° C. (212° F.) and not above 150° C. (302° F.), the metal becomes malleable and ductile; above 200° C. (392° F.), it becomes sufficiently brittle to be (powdered in an iron mortar; at from 412° to 415° C. (773.6°–779° F.) it melts, and at 940° C. (1724° F.) it boils and may be readily distilled. Add 1 Gm. of Zinc to 25 mils of diluted sulphuric acid; the liberated hydrogen does not have a disagreeable odor, nor does it color a strip of paper moistened with lead acetate T.S. (*sulphur*), or with silver nitrate T.S. (*arsenic, antimony, and phosphorus*). The filtered solution is colorless, and yields a white gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S." *U. S.*

Assay.—"Dissolve about 1 Gm. of Zinc, accurately weighed, in a slight excess of hydrochloric acid and add sufficient distilled water to make 100 mils. Dilute 10 mils of the clear solution with distilled water to make 100 mils, render it slightly alkaline with ammonia water and subsequently treat it as directed in the assay for *Zinci Acetas* for the determination of zinc oxide. The metal yields an amount of zinc oxide corresponding to not less than 99 per cent. of Zn.

"Each gramme of Zinc corresponds to not less than 1.232 Gm. of ZnO. Zinc may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

Zinc of good quality dissolves in diluted sulphuric acid, with the exception of a scanty grayish-black residue. If absolutely pure, it would be wholly dissolved. The solution is colorless, and yields white precipitates with potassium ferrocyanide and ammonium sulphydrate. Ammonia throws down from this solution a white precipitate, which is wholly dissolved when the alkali is added in excess. Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction with copper or carbon, for galvanic combinations.

Its solution in diluted sulphuric acid furnishes the readiest method for obtaining hydrogen. With copper it forms *brass*, and, in the form of *sheet zinc*, it is employed to cover the roofs of houses, to line sinks, put under stoves, and for other purposes. It is also applied to the covering of iron, to protect it from oxidation, in the same manner as tin, forming what is commercially known as *galvanized iron*. A fine powder, known as *zinc dust*, obtained by the condensation of zinc vapor in the distillation of zinc from its ores, is much used in chemical laboratories as a convenient reducing agent in many reactions. Zinc should never be used for culinary vessels, as it is soluble in the weakest acids. Zinc and its oxide are dissolved to a certain extent by water containing common salt, a double zinc and sodium chloride being produced in solution. (*J. P. C.*, Nov., 1867, p. 397.)

Zinc Nitrate is sometimes used as a caustic either in the form of *paste* or in *pencils*. Lefort prepares it by dissolving commercial zinc with heat in equal volumes of nitric acid and water, maintaining an excess of zinc, and concentrating until a slight basic precipitate is formed, which carries down any iron present. Boiling water is then added, and, when cool, the solution is filtered, and evaporated at a gentle heat until slight ebullition takes place; if then left to cool, it forms a cake, which should be broken up and drained in a glass funnel. Of the zinc nitrate so prepared, 100 grammes are dissolved in 50 grammes of water, and afterwards incorporated with 50 grammes of wheaten flour. This forms a homogeneous paste, which remains soft, spreads easily over surfaces without afterwards contracting, and does not spread at the edges through absorption of moisture. When made into cylinders, it should not be dried by heat, as it slightly decomposes and becomes yellow and friable; it may be kept dry by placing it in a tin box with some pieces of quicklime, but not in contact with them. (*L. M. R.*, June 18, 1873; *A. J. P.*, Dec., 1873.) Chas. Rice prepares pencils by pouring fused zinc nitrate into paper cylinders which are made by rolling paper around a lead-pencil and sealing with wax. The mixed *mercury and zinc cyanide* was originally suggested as a practical antiseptic by Lister, who claimed for it the advantages of being non-volatile, unirritating, insoluble in water, and soluble only in three thousand parts of blood serum; so that it is not easily washed off the gauze by discharge from wounds. Its germicidal value is said to be very slight, but its inhibitory power to be such that a one twelve-hundredth solution will permanently prevent putrefaction in animal fluids. (See *N. R.*, 1876, p. 44; also *Mercuric and Zinc Cyanide*, Part II.) *Cyanide gauze* may be made actively germicidal by impregnation with a solution of one to four thousand of corrosive sublimate.

The compounds of zinc are poisonous, but not to the same extent as those of lead. The zinc oxide, used in painting as a substitute for white lead, is said to be capable of producing a colic resembling that caused by lead, and called *zinc colic*. It attacks the workmen exposed to the dust of the oxide while engaged in packing it in barrels, and is said to yield to the remedies appropriate to the treatment of lead colic. This latter statement, however, is, to say the least, very questionable.

Uses.—Zinc is never used as a medicine in the metallic state, but is employed in this state to prepare zinc sulphate and zinc chloride, and the Reduced Iron of the Br. Pharmacopœia. In combination it forms a number of important preparations.

ZINGIBER. U. S., Br.

GINGER Zingib.

(zĭn'jĭ-bẽr)

"The dried rhizomes of *Zingiber officinale* Roscoe (Fam. *Zingiberaceæ*), the outer cortical layers of which are often either partially or completely removed. Preserve it in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.* "Ginger is the scraped and dried rhizome of Zingiber officinale, *Roscoe*." *Br.*

Gingembre (gris et blanc), *Fr. Cod.*; Rhizoma Zingiberis, *P. G.*; Ingwer, *G.*; Zenzero, *It.*; Jengibre (Rizoma de), *Sp.*

There are about twenty species of the genus Zingiber, the commercial ginger being obtained from *Zingiber officinale*. According to Watt, this species is probably a native of tropical Asia, but is not known except in the cultivated state. It is now extensively cultivated in the tropical countries of both the Eastern and Western Hemispheres.

The ginger plant, *Zingiber officinale*, has a biennial or perennial, creeping rhizome, and an annual stem, which rises two or three feet in height, is solid, cylindrical, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The flower-stalk rises by the side of the stem from six inches to a foot, and, like it, is clothed with oval acuminate sheaths; but it is without leaves, and terminates in an oval, obtuse, bracteal, imbricated spike. The flowers are of a dingy yellow color, and appear two or three at a time between the bracteal scales. The flowers have an aromatic odor, and the stems when bruised are slightly fragrant; but it is in the rhizome that the virtues of the plant reside. This is fit to be dug up when a year old. The rhizome of the ginger is lifted from the soil by a single thrust of the fork at the time when the stems of the plant turn white, before the rhizome has begun to get tough and fibrous. The root is scalded in boiling water and rapidly dried, when it constitutes the *black* or ordinary ginger of commerce.

In Jamaica the so-called *white* or *Jamaica ginger* is produced by carefully peeling the fresh rhizomes so that only the epidermis is removed,

the cells immediately beneath the epidermis being the richest in volatile oil and resin. The peeled pieces are macerated sometimes in water and sometimes in lime juice, and not rarely the color of the ginger is improved by finally coating it with chalk. (See Kilmer, *A. J. P.*, 1898, p. 65; Harris, *P. J.*, 1909, xxix, p. 379.) An inferior white ginger is also produced in the East Indies. The thoroughness of desiccation is a matter of commercial importance. The moisture in ginger should not exceed 10 per cent., but in the poorer specimens may constitute one-fourth of the whole weight. In China the fresh ginger is rasped into a powder and as such dried. Formerly *East Indian ginger* was imported into the United States from Calcutta, while the *Jamaica* or *West Indian ginger* came usually through London. At present the cultivation of ginger is spread almost over the whole sub-tropical world, and the drug is produced in St. Lucia, Dominica and Africa, Cochin-China, Japan, etc. The world's production of ginger is estimated to be annually over 20,000,000 pounds. Of this nearly 4,000,000 pounds is annually exported from Jamaica, the United States using about 1,500,000 pounds. (*C. D.*, lxxvii, p. 489; *Cons. and Tr. Rep.*, 1910, p. 1085.)

In Martinique a ginger is said to be obtained by the cultivation of *Zingiber Zerumbet* Rosc. The ginger of Siam is said to be produced by *Alpinia Galanga*, and is the same drug, therefore, as the *Greater* or *Java Galanga Root*. The large, ordinary, *preserved ginger* of China is, according to C. Ford (*Kew Bulletin*, 1891) also the product of *A. Galanga*. It is made by boiling young, tender, carefully selected and decorticated rhizomes in syrup. Preserved ginger from the West Indies is made from the official plant. According to Hartwich and Swanlund, the rhizome of the *Zingiber Mioga*, which is cultivated in China and Japan, has a taste less pungent than that of the official ginger, and distinctly recalling bergamot. In commerce the varieties of ginger are known by the place of their production. African and Cochin ginger on an average yield more resin and volatile oil than do the older varieties.

The recent root is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light ash color with circular rugæ, internally yellowish-white and fleshy. It sometimes begins to grow when kept in a damp atmosphere. The *common* or *black ginger* is of the same general shape, but has a dark ash-colored wrinkled epidermis, which, being removed in some places, exhibits patches of an almost black color, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish, the cells being filled with starch. The powder is of a light yellowish-brown color. This variety is most extensively used. The *Jamaica* or *white ginger* is white or yellowish-white on the outside. The pieces are rounder and thinner, and afford when pulverized a beautiful yellowish-white powder.

The uncoated ginger of the East Indies resembles the Jamaica, but is darker, being gray rather than white. As the Jamaica commands a much higher price than even the uncoated East India production, the latter is occasionally altered to simulate the former. This is sometimes done by coating the exterior with calcium sulphate or carbonate, sometimes by bleaching with the fumes of burning sulphur or in other ways, by which not only the exterior but also the internal parts are rendered whiter than in the unprepared root. Powdered ginger which has been exhausted in the preparation of essence, technically known as "*spent ginger*," is used to a large extent in the adulteration of powdered ginger. Its detection without assay of some sort is almost impossible, unless so much is present as to sensibly alter the taste of the powder. Allen and Moor rely upon the proportion of cold water extract yielded and the soluble ash. Dyer and Gilbard state that the fixed ethereal extract is of little value, on account of its variability in genuine ginger, but that the extract obtained by alcohol after ether affords a valuable criterion. In genuine ginger the average yield is 2.9 per cent. while in spent ginger it is 1.2 per cent. They also affirm that in genuine ginger the ash produced is 2.7 per cent., in the exhausted ginger it is 0.3 per cent. A. Russell Bennett concludes that spent ginger can be detected by noting the alcoholic and cold water extracts and the soluble ash, affirming that ginger should yield not less than 5 per cent. of extract with 90 per cent. alcohol, 8.5 per cent. of cold water extract and 1.5 per cent. of soluble ash.

Commercial gingers are known as "scraped," "decorticated," and "coated." The "scraped" gingers are those from which the cortex has been removed in whole or in part by peeling, as seen in the Jamaica, Cochin and Japan varieties. In the "coated" gingers a portion of the outer natural layers are retained as in the African, Calcutta and Calicut varities. "Bleached" and "unbleached" gingers are also distinguished, the former being lighter in color due to careful washing or special treatment. All of the above varieties mentioned are recognized in the U. S. Pharmacopœia IX, and are described as follows:

"**Jamaica Ginger.**—Rhizomes free from the outer corky layers, in horizontal, laterally compressed, irregularly branched pieces, from 4 to 16 cm. in length; and from 4 to 20 mm. in thickness; externally light brown, longitudinally striate, ends of the branches with depressed stem-scars; fracture short-fibrous, mealy and resinous; internally yellowish to light brown, cortex thin, endodermis a thin yellow layer enclosing a large central cylinder with numerous groups of fibro-vascular bundles and yellowish oil cells; odor agreeably aromatic; taste aromatic and pungent.

"**African Ginger.**—Rhizomes with cork partly removed on the flattened sides, the patches without cork smooth and of a light brown color, the

portions with cork longitudinally or reticulately wrinkled and grayish-brown; fracture short or short-fibrous, internally lemon-yellow or dark bluish with yellowish oil-secretion cells and light yellow to reddish-brown resin cells; odor strongly aromatic; taste intensely pungent.

"**Calcutta Ginger.**—Rhizomes resembling the African Ginger, the branches or 'fingers' being somewhat larger, and with a considerable proportion of shriveled pieces, externally grayish-brown or grayish-blue; fracture short and mealy, or horny; internally light yellow or light brownish-yellow with numerous yellowish oil cells and yellowish-brown resin cells; odor aromatic; taste starchy and strongly pungent.

"**Calicut Ginger.**—Rhizomes resembling African Ginger, more of the periderm being usually removed; externally more or less uniformly light brown; fracture short or short-fibrous, and mealy; internally light-yellow or brownish-yellow with numerous yellowish oil and resin cells; odor aromatic; taste very pungent.

"**Cochin Ginger.**—Rhizomes with most of the corky layer removed on the flattened sides; externally light brown to grayish-yellow, fracture short and mealy; internally yellowish-white with numerous yellowish oil cells and brownish-red or blackish resin cells; odor aromatic; taste pungent but not so persistent as in the African variety.

"**Japanese Ginger.**—Rhizome somewhat resembling Cochin Ginger but usually with a thin coating of lime; externally nearly smooth or slightly wrinkled and of a whitish color; fracture short and very mealy; internally varying from a yellowish-white to light brown and with numerous brownish-red resin cells; odor aromatic; taste pungent.

"Powdered Ginger is light yellow, or light brown to dark brown; under the microscope it exhibits numerous starch grains varying greatly in form and size in the different varieties, being nearly spherical, ovoid, ellipsoidal or pear-shaped and frequently with a characteristic beak, usually from 0.005 to 0.04 mm., occasionally from 0.045 to 0.06 mm. in the long diameter; sclerenchymatous fibers long, thin-walled, non-lignified, with oblique pores and distinctly undulate on one side; oil-secretion cells with suberized walls and containing a light yellowish or yellowish-brown, oily substance; cork cells absent in the Jamaica variety. Introduce 4 Gm. of ground Ginger into a 200 mil flask, fill to the mark with distilled water, and agitate at half-hour intervals during eight hours. Then allow the mixture to stand for sixteen hours, and filter. Evaporate 50 mils of the filtrate, representing 1 Gm. of the drug, on a water bath, dry to constant weight at 100° C. (212° F.) and weigh; it yields not less than 8 per cent. of residue. Ginger yields not less than 2 per cent. of a non-volatile extract soluble in ether and not less than 4 per cent. of an extract soluble in alcohol. Ginger yields not more than 8 per cent. of ash." *U. S.*

"In flattish, irregularly branched pieces, usually from seven to ten centimetres long; each branch marked at its summit by a depressed scar. Fracture short with projecting fibres. Agreeable, aromatic odor; taste pungent. When 5 grammes of powdered Ginger are shaken with 100 millilitres of *alcohol* (90 per cent.) occasionally during twenty-four hours and filtered, 20 millilitres of the filtrate yield on evaporation not less than 0.050 gramme of residue dried at 100° C. (212° F.); and when 5 grammes are similarly treated with 100 millilitres of *water*, 20 millilitres of the filtrate yield not less than 0.085 gramme of residue dried at 100° C. (212° F.). Ash not more than 6 per cent.; and after deduction of that portion of the ash which is soluble in *water* not more than 1.5 per cent." *Br.*

The odor of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and are ultimately lost, by exposure. The morphology and pharmacognosy of ginger have been studied by Meyer (*Wissenschaftliche Drogenkunde*, vol. ii, p. 64) and Tschirch and Oesterle (*Anatomischer Atlas.*, Lief. vi, p. 109). Kraemer and Sindall have published an article on the "Microscopical and Chemical Examination of the Different Varieties of Commercial Ginger" (*A. J. P.*, 1908, p. 303). Spaeth reports on the adulteration and detection of adulterants of ginger and asserts that the more common adulterants are flour, curcurma, linseed and rapeseed cake, cayenne pepper hulls, and extracted ginger. (*Zeitschr. f. Unters. d. Nahr. u. Genussm.*, x, p. 23.)

The use of capsicum in preparations of ginger is not infrequent. When present, it may be detected by the method described under tincture of ginger (see page 1159).

The virtues of ginger are extracted by alcohol. The peculiar flavor of the root appears to depend on the volatile oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of pure white starch may be obtained from it. The volatile oil, examined by A. Papousek, was yellow, of the odor of ginger, and of a hot aromatic taste. Its sp. gr. was 0.893, and its boiling point 246.1° C. (475° F.). Deprived of water by distillation over phosphoric oxide, it consisted of carbon and hydrogen, with the formula $C_{10}H_{16}$, and therefore belongs to the terpenes. Tresh considers that the essential oil is mainly made up of a hydrocarbon, $C_{15}H_{24}$, or isomers of it, which boil at from 245° to 270° C. (473°–518° F.). (*P. J.*, No. 586, 1881.) Schimmel & Co. (*April*, 1897) state that the essential oil contains *camphene* and *phellandrene*, and hence the terpenes have the formula $C_{10}H_{16}$, as first stated. Flückiger obtained from one hundred and twelve pounds of Jamaica ginger four and a half ounces of the oil, or about one-fourth of one per cent. He states, however, that Schimmel & Co., of Leipsic, informed him that they obtained as much as 2.2 per cent. from good ginger. (*Pharmacographia*, 2d ed., p. 637.) H. von Soden and W. Rojahn (*Ph. Ztg.*, 1900, 414) obtained a new sesquiterpene from oil of gin-

ger by fractioning the saponified oil. They have named it *zingiberene.* It has the sp. gr. 0.872 at 15° C. (59° F.). Those pieces of ginger which are very fibrous, light and friable, or worm eaten, should be rejected. The commercial powder of ginger is very frequently adulterated, rice starch, powdered ginger which has been exhausted in making preparations, and even brick dust and chalk, being used, and the loss of pungency made good by the addition of capsicum or mustard.

Uses.—Ginger is a grateful stimulant and carminative, and is often given in *dyspepsia* and *flatulent colic.* It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. It is especially valuable in *alcoholic gastritis.* In the serous type of *diarrhea,* when due to a relaxed condition of the bowel, it is a remedy of much service but should not be employed in the presence of inflammatory conditions. The hot infusion is popularly employed under the name of "Ginger Tea" for its diaphoretic effect in *colds,* especially when accompanied with suppression of the menses. Externally it is rubefacient. Under the name of *"Essence of Ginger"* cheap alcoholic preparations of ginger were formerly sold and used as intoxicants. A number of cases of blindness produced by such use have been recorded, the amblyopia having been due to the large use of methyl alcohol in the making of these "essences." The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluidounces (30–60 mils).

Dose, ten to twenty grains (0.65–1.3 mils).

Off. Prep.—Fluidextractum Zingiberis, *U. S.;* Infusum Sennæ, *Br.;* Oleoresina Zingiberis, *U. S.;* Pilula Scillæ Composita, *Br.;* Pilula Urgineæ Composita, *Br.;* Pulvis Aromaticus, *U. PART II

DRUGS AND MEDICINES NOT OFFICIAL

In the present section it is proposed to consider remedies which are not recognized in the United States or British Pharmacopœias, but which, on account of their use in domestic or professional medicine, their toxic properties, their history, or the probability that they may prove in the future remedies of power, or valuable products, require notice in an encyclopedic work like the United States Dispensatory. The limit of the present volume forbids an exhaustive description of all these substances, but the attempt is made to give at least the essential information and the key to the literature about almost everything used in medicine. The substances treated of in this part are not considered to be of as great importance as those found in Part I, and hence the type and arrangement of titles are different; experience has shown that this method helps to educate the reader to distinguish between official and unofficial substances.

Abrastol. *Asaprol. Calcium betanaphtholsulphonate. Calcinaphthol.—Calcium α-monosulphonate of β-naphthol,*

$$C_{10}H_6\begin{cases}OH\\SO_3\end{cases}\!\!>Ca + 3H_2O.$$
$$C_{10}H_6\begin{cases}SO_3\\OH\end{cases}$$

This is a pinkish powder, soluble in water and alcohol, and resembling the salicylates in its taste. It is neutral in reaction, readily soluble in alcohol and water, and not altered by heat. On exposure to light and air it tends to darken and become less soluble. It is incompatible with quinine salts, antipyrine, ferric salts, and potassium iodide, soluble carbonates and oxalates, and when rubbed with some of the synthetic drugs, exalgin, urethane, etc., it forms masses. Asaprol was originally brought forward by A. Stackler as a germicide, antipyretic, and antirheumatic in *rheumatism, typhoid fever,* etc. (*B. G. T.,* 1892.) Dujardin-Beaumetz (*B. G. T.,* Jan., 1894) found that when given by the mouth to rabbits in the dose of 0.25 Gm. per kilo it has no deleterious effect, although less than 1 Gm. per kilo proved fatal. It escapes from the kidneys in the form of *naphthol sulphuric ester,* which may be recognized by the dark blue coloration of the urine on the addition of ferric chloride. In acute *rheumatism,* Dujardin-Beaumetz believed that the remedy is equal to salicylates, and that it has the advantage of not producing tinnitus aurium or eruptions upon the skin. Buck (*Ther. Woch.,* 1897) confirms the value of asaprol in *rheumatism.* Moncorvo (*B. G. T.,* March and April, 1895) recommends it in *chorea* and in *malarial diseases.* He also affirms that, used locally, it is an excellent antiseptic, hemostatic, and cicatrizant. He uses it in aqueous solution, 1 to 4 per cent., or as an ointment with vaseline. He even asserts that a 1 per cent. solution applied to the periglotteal region will rapidly cure *whooping cough.* It has been used to a limited extent as a food preservative, particularly for beverages, and is prohibited by statute in a number of states. It is detected by the yellow coloration produced by mercuric nitrate T.S. when added to the residue obtained by shaking out the acidulated solution, of the substance suspected of containing it, with ether, and evaporating the ether on a watch glass. The *dose* of abrastol is from ten to thirty grains (0.6–1.9 Gm.) three times a day.

Abroma. *Abroma angustum* L. f. (Fam. *Sterculiaceæ.*)—Under the name of *Olutkombul,* the glutinous sap of this plant has long been used in India in *dysmenorrhea.* According to Sircar (*Indian Medical Gazette,* 1900) and other English practitioners, it is a very efficient remedy in congestive and neuralgic *dysmenorrhea* when given in doses of two drachms (7.7 Gm.) at the time of the first premonitory pains and continuing to the end. The fresh root is sometimes used. *Dose,* half a drachm (2 Gm.).

Abrus. *Abri Semina. Jequirity. Prayer Beads. Abrus Seeds. Abrus precatorius* L. (Fam. *Leguminosæ.*)—The seeds of this plant, which grows in India and also in Brazil, are employed in India as a standard weight by druggists and jewelers, and also for criminal poisoning. The seeds are ovoid, from 5 to 8 mm. in length, smooth, shiny and of a bright scarlet, having a black marking at the lower, or hilum, portion. They are said to be inert when taken whole into the stomach. They contain *abric acid,* $C_{21}H_{24}N_3O$, and, according to the researches of Sidney Martin (*P. J.,* Sept., 1887; *Proc. Roy. Soc.,* 1889, vol. xlvi), two proteid poisons, a paraglobulin and an albumose (together called *abrin*), which are almost identical in their physiological properties with principles found in snake venom, although less powerful. According

to Flexner, the toxic action of these substances also closely resembles that of true toxins, the most characteristic result being focal necroses in various organs. Flexner suggests that these in turn are due to a lesion in the blood-vessel walls caused by the abrin. (*J. Ex. M.*, 1897, vol. ii.) The ordinary lethal dose of abrin for animals is said to be 0.00001 Gm. per kilo of weight. (Consult *The Non-Bacillous Nature of Abrus Poisoning*, J. H. Warden and L. A. Waddel, Calcutta, 1884; Bufalini, *Ann. di Chim. e di Farm.*, No. 2, 1886; Kobert, *W. M. Bl.*, Nov., 1889.) The root of Abrus, known as *Indian liquorice*, possesses toxic properties like the seeds and should not be used in place of licorice. According to David Hooper, it contains *glycyrrhizin*. (*P. J.*, 1894.) Abrin is used in the treatment of certain chronic diseases of the eye, especially in *corneal opacities*, and *trachomatous pannus*. It excites a purulent inflammation of the conjunctiva, which appears to lead to an increase in the local circulation, provoking thereby an absorption of inflammatory exudates. The remedy is capable of great harm in unsuitable cases, and extreme caution must be employed in its use. The infusion of jequirity, which was formerly employed for this purpose, has been almost abandoned because it was liable to cause an uncontrollable inflammation which in some instances has entirely destroyed vision. The infusion of the crude drug was employed in strengths of from 2 to 20 per cent., which must be prepared at a temperature below 50° C. (112° F.). According to Ehrlich, the solution of abrin should not be stronger than one part in 500,000; any increase of strength must be made with great care. Both Ehrlich and Calmette succeeded in immunizing rabbits against abrin, and obtained an antitoxic serum. P. Römer (Graefe's *Archiv. f. Ophthal.*, vol. lii, 1901) has introduced two preparations: *jequiritol*, an abrin solution, sterilized, of four different strengths; *jequiritol serum*, which, as commercially supplied, has such immunizing power that 0.1 mil suffices to protect a white mouse from the effects of a hundredfold lethal dose of jequiritol when the latter and jequiritol serum are injected conjointly. (For details and methods of use, see *Th. M.*, May, 1902; *M. R.*, 1902; Kattwinkel, *Jequiritol*, Bonn, 1902; Seefelder, *Klinische monatsblätter*, 1905, p. 273; Schoen, *Hospitalstidende*, No. 37, p. 921.)

Absinthium. *N. F. IV. Wormwood.*—It was official in the U. S. P. 1890 and is now recognized by the National Formulary. The definition is as follows: "The dried leaves and flowering tops of *Artemisia Absinthium* Linné (Fam. *Compositæ*), without the presence of more than 5 per cent. of foreign matter." *N. F. IV.* Several species of Artemisia have enjoyed some reputation as medicines. The leaves of *A. Abrotanum* L., or *southernwood*, are reported by Craveri to contain a crystallizable alkaloid, *abrotine;* they were formerly employed as a tonic and anthelmintic. *A. pontica* L. has been substituted for common wormwood, but is weaker. *A. vulgaris* L., or *mugwort*, has been used in Germany in *epilepsy, chorea*, and *amenorrhea*. *A. ludoviciana* Nutt., a native of the southwestern regions of the United States, has been commended as a stimulant to the hair. (*A. J. P.*, 1872, p. 106.) In China, *moxa* is prepared from *A. chinensis* L. and *A. indica* Willd.

Wormwood, also known as *Madderwort, Wermuth, Mugwort, Mingwort* and *Warmot*, is a shrubby, more or less herbaceous, finely canescent plant, growing to a height of 2 to 4 feet. The leaves are 1 to 3 pinnately divided, the lobes being lanceolate or obovate, the basal leaves being petiolate while the floral ones are linear and entire; the flowers are all fertile, yellowish, and occur in hemispherical panicled heads. The plant is a native of Europe and is to some extent cultivated in the United States. It is now naturalized and rather common in eastern Canada to Pennsylvania, growing along roadsides and waste places. It should be gathered in July or August, during flowering.

The N. F. description is as follows: "Stems and leaves gray-green, finely silky-hairy and glandular throughout; largest leaves reaching 10 or 12 cm. in length, and of nearly equal breadth, on long petioles, two to three times pinnately lobed or divided, the ultimate segments oblong or obovate, obtuse, entire or slightly toothed; upper leaves becoming shorter petioled, small and narrower, the uppermost being only about 2 cm. in length and resembling the ultimate segments of the larger ones; heads racemose-paniculate, drooping on short peduncles, greenish-yellow, from 3 to 4 mm. in breadth, round-ovoid, the outer bracts linear-oblanceolate, obtuse, the inner broader and scarious-margined; receptacle hairy; outer flowers sometimes pistillate. Odor characteristic, aromatic; taste very bitter. The powdered drug is brownish to yellowish-green and, when examined under the microscope, exhibits numerous, characteristic, T-shaped, non-lignified hairs, consisting of a short, one- to four-celled stalk bearing a single apical cell attached near the center and up to 0.8 mm. in length and 0.035 mm. in width. Many of the hairs are more or less collapsed, twisted or broken; glandular hairs, some with one- or two-celled stalk, the glandular portions consisting of from four to eight secreting cells surrounded by a membrane; few simple hairs from the flowers, some of which are very long and up to 0.085 mm. in width; epidermal fragments with elliptical stomata, the latter up to 0.035 mm. in length; fragments of mesophyll and palisade cells containing chloroplastids; tracheæ mostly spiral, up to 0.035 mm. in width; few sclerenchymatous fibers, with thick, usually lignified walls and simple pores, up to 0.02 mm. in width; pollen grains few, somewhat spherical or triangular in outline, up to 0.03 mm. in diameter; calcium oxalate crystals in rosette aggregates about 0.01 mm. in diameter. Absinthium yields not more than 10 per cent. of ash." *N. F.*

The volatile oil (*oleum absinthii*) is usually dark green, sometimes yellow or brownish or even blue, having a strong odor of the plant, an acrid peculiar taste, and the sp. gr. 0.925 to 0.950. It is sometimes adulterated with alcohol, oil of turpentine, etc., which lessen its specific gravity. It is composed of: *thujone* (*absinthol*), which has the specific gravity 0.926, composition $C_{10}H_{16}O$, boiling point 200° C. (392° F.) to 205° C. (401° F.), and when heated with phosphorus pentasulphide or zinc chloride yields cymene ($C_{10}H_{14}$); thujyl alcohol ($C_{10}H_{18}O$), both free and as the esters of acetic, isovaleric, and palmitic acids; phellandrene and possibly pinene; cadinene; and a *blue oil* of as yet undetermined composition. (Gildemeister and Hoffmann, *Aetherische Oele*, 1899.) The *absinthic acid* found by Braconnot is said to be succinic acid. Caventou first obtained *absinthin* in an impure condition. (See U. S. D., 14th ed., p. 5.) P. Senger (*A. Pharm.*, 230, p. 94) has obtained absinthin as a yellow substance of an intensely bitter taste

melting at 55° C. (131° F.). He gives it the formula $C_{15}H_{20}O_4$ and considers it to be a glucoside, as on boiling with diluted sulphuric acid it yields dextrose and absinthic acid. Kromayer gives the formula for absinthin as $C_{40}H_{56}O_8 + H_2O$. Absinthin is soluble in water, alcohol, and ether and has been introduced into medicine for use in the treatment of *constipation* and *chlorosis*. *Dose*, one and one-half to three grains (0.1–0.2 Gm.). Adrian and Trillat isolated a new crystalline body ($C_{53}H_{51}O_{20}$) from wormwood by treating an alcoholic extract with amyl alcohol, the absinthin having been previously removed. They also isolated another crystalline principle, *anabsinthin*, $C_{18}H_{24}O_4$ (*P. J.*, 1899, 1, 75). The old *salt of wormwood* (*sal absinthii*) was impure potassium carbonate, made from the ashes of the plant.

Wormwood, which was formerly in vogue as a stomachic tonic, antiperiodic, and anthelmintic, is at present very seldom used. The volatile oil is an active narcotic poison. In dogs and rabbits from thirty to fifty drops (1.5–2.5 mils) of it will cause trembling, stupor, hebetude, and even insensibility; one to two fluidrachms (3.75–7.5 mils) of it causes violent epileptiform convulsions, with involuntary evacuations, unconsciousness, and stertorous breathing, which may or may not end in death. (Marcé, *B. G. T.*, Mai, 1864; Amory, *B. M. S. J.*, March, 1868, p. 83.) In man the oil acts similarly; a half ounce (15 mils) of it caused, in a male adult, insensibility, convulsions, foaming at the mouth, and a tendency to vomit; though the patient recovered under the use of emetics, with stimulants and demulcents. (*L. L.*, Dec. 6, 1862.) According to J. L. Corning, the volatile oil is a powerful local anesthetic, locally useful in *rheumatic pains*. Böhm and Kobert affirm that the oil escapes through the kidneys unchanged. *Dose*, of wormwood in substance, from twenty to forty grains (1.3–2.6 Gm.); of the infusion (one ounce in a pint of boiling water), from one to two fluidounces (30–60 mils); of the oil, one to two minims (0.06–0.12 mil).

Absinthe is a liqueur containing oils of wormwood, angelica, anise, and marjoram. According to Baudrimont, the *absinthe ordinaire* contains 47.66 per cent. of alcohol, the *demi-fine* 50 per cent., the *fine* 68 per cent., and the *absinthe Suisse* 80.66 per cent. The preparation, if manipulated properly, possesses naturally a bright green color, brought to an olive-green by slight addition of caramel coloring; but artificial coloring was formerly often resorted to, and indigo, turmeric, cupric acetate, and aniline green have been used to produce the proper shade. The importation of absinthe liqueur into the United States is now prohibited by law. *Absinthism* differs from ordinary alcoholism in its manifestations; its characteristic symptoms are restlessness at night, with disturbing dreams, nausea and vomiting in the morning, with great trembling of the hands and tongue, vertigo, and a tendency to epileptiform convulsions.

Acalypha. *Br. Add.* 1900.—The fresh and the dried herb, *Acalypha indica* L. This euphorbiaceous plant is said to have expectorant and emetic properties similar to those of ipecac, and also to be employed by the native Indian practitioners in the form of the fresh leaves as a poultice for *ulcers*, and as a suppository for *constipation* in children. The *Succus Acalyphæ*, Br. Add., 1900, is prepared by adding one volume of 90 per cent. alcohol to three volumes of the juice expressed from fresh leaves, with subsequent filtration. It is given in doses of from one to four fluidrachms (3.75–15 mils). The *liquid extract* (*Extractum Acalyphæ Liquidum*, Br. Add., 1900), made with a menstruum of 90 per cent. alcohol, is given in doses of from five to thirty minims (0.3–1.8 mils).

Acetal. *Acetol. Diethylacetal. Diethylaldehyde.* $C_6H_{14}O_2$ or $CH_3CH(OC_2H_5)_2$.—*Ethidene* (*Ethylidene*) *diethylic ether*, a limpid volatile liquid boiling at 103°–104° C. (219°–223° F.), sp. gr. 0.831 at 22° C. (71.6° F.), and produced by the imperfect oxidation of alcohol. Sparingly soluble in water, readily soluble in alcohol, is stated to be narcotic in the *dose* of thirty minims (1.8 mils). Used as a hypnotic in *doses* of two or three fluidrachms (8–12 mils), preferably in emulsion. The title Acetal is also given to a proprietary remedy for *headache*.

Acetonitrile. *Methyl Cyanide.* CH_3CN. (C_2H_3N).—This is a colorless liquid, with a characteristic odor, miscible with both water and alcohol, and prepared from acetamide with glacial acetic acid by heat. Although it is probable that it is partly broken up in the system, methyl cyanide is not highly toxic. According to Lang (*A. E. P. P.*, 1894, xxxiv, p. 24), the fatal dose for rabbits is about one gramme. About one-fifth of the cyanogen which is introduced in the radical may be recovered from the urine in the form of an alkaline sulpho-cyanide. Its chief importance lies in the fact that it has been suggested by Hunt (*A. I. P. T.*, 1904, xii, p. 44) as a means for the biological standardization of the thyroid gland. (See *Thyroideum Siccum.*)

Aceto-Ortho-Toluid. *Ortho-tolyl-acetamid.* $C_7H_7.NH.C_2H_3O$.—Colorless needles, easily soluble in hot water, alcohol, and ether; powerfully depressant to animal temperature, although feebly poisonous. Used as an *antipyretic* in *doses* of from three to eight grains (0.2–0.5 Gm.). (E. Barbarini, *T. Mod.*, 1892, 532.)

Aceto-Para-Toluid. $C_6H_4(CH_3)NH.C_2H_3O$.—Colorless crystals slightly soluble in water, used in doses of fifteen to thirty grains (1.0–2.0 Gm.) as an *antipyretic*.

Acetophenone. *Hypnone. Phenyl-methyl-ketone. Phenylmethylacetone.* C_8H_8O or $C_6H_5CO.CH_3$.—A colorless liquid, boiling at 200° C. (392° F.), sp. gr. 1.035, having a very tenacious, persistent odor, suggesting that of bitter almonds and jasmine, not inflammable, not soluble in water or in glycerin, but very soluble in alcohol, ether, chloroform, petroleum benzine, and also certain fixed oils, especially that of sweet almonds. It is made by distilling a mixture of calcium acetate and benzoate. It was originally proposed as a somnifacient but has been shown to be both uncertain as a hypnotic and toxic in its action. The researches of Regnier, confirmed by Kamensky, have demonstrated that it acts powerfully on nutrition, rapidly lessening the hemoglobin in the blood and causing loss of weight. Norman, however, claims excellent results from hypodermic injections of from five to twelve minims (0.3–0.7 mil) in *insanity*. (*J. M. S.*, xxxiii.) *Dose*, from three to ten minims (0.2–0.6 mil), although Rey has given as much as twenty-three minims (1.5 mils) without producing sleep. It is usually administered in solution in olive or almond oil (1 in 10) either in gelatin capsules or suspended in an emulsion.

Acetophenone-Paramidophenol Ether.—This substance, prepared by G. Vignolo, has been studied physiologically by F. Badano (*Arch. I. C. M.*, xxxvi, 1897), who finds that it powerfully reduces bodily temperature by lessening the heat

production; that in poisonous doses it causes the formation in the blood of methemoglobin, and kills by respiratory paralysis.

Acetopyrine. *Acopyrin. Pyrosal. Antipyrinæ Acetyl-salicylas.*—This occurs as a white, crystalline powder, having an odor resembling acetic acid; melting point 63°–65° C. (145.4°–151° F.); sparingly soluble in cold but freely in warm water; freely soluble in alcohol, chloroform, and in warm toluol; less so in ether and in petroleum benzin. It was originally introduced into medicine by Winterberg and Braun (*W. K. W.*, 1900, No. 39) as combining the activities of antipyrine and acetyl-salicylic acid, into which substances, according to W. Meitner (*St. P. M. W.*, xx, 1900), it is broken up in the stomach; the acetyl-salicylic acid undergoing further decomposition in the intestines. Acetopyrine has been much used as an analgesic in *migraine, sciatica, neuritis,* and also as an antipyretic in *typhoid* and other low fevers. It has also been employed as an antirheumatic, especially in subacute and chronic cases. Goldmann (*All. W. M. Z.*, April, 1901) claims that it is valuable in *bronchitis;* and Bolognesi (*B. G. T.*, March, 1901) recommends it in *gonorrhea.* Its physiological and therapeutic activities are probably those of its constituents. It may be given in *doses* of five to ten grains (0.32–0.65 Gm.), in capsules or suspended in water, and repeated up to thirty grains (2 Gm.) in the twenty-four hours when necessary. In fevers two doses may be given two hours apart about the time of the exacerbation. Its incompatibilities are the same as those of antipyrin, it being also incompatible with iron compounds and acids.

Acetylene. C_2H_2.—Acetylene was first prepared by Berthelot, who obtained it by passing the electric spark between carbon points in an atmosphere of hydrogen. It is now prepared on a large scale by the decomposition of carbides, like calcium carbide, with water according to the reaction:

$$CaC_2 + 2H_2O = C_2H_2 + Ca(OH)_2$$

The product so obtained is almost always contaminated with phosphine, and this should always be removed by washing the acetylene with bromine water. It is produced by a number of other methods involving the reduction of higher hydrocarbon and is produced to a limited extent when the flame of a bunsen burner or gas stove strikes back and burns at the base, giving rise to its characteristic odor, by which the condition of the burner is frequently detected.

Acetylene is a colorless gas of ethereal odor, slightly soluble in water, more readily in alcohol and ether, and most abundantly in acetone. It burns ordinarily with a very smoky flame, but from a burner with a fine slit gives a clear white flame. It forms an explosive mixture with air, also a series of explosive compounds with copper, silver, and other metals. These compounds are in reality the carbides of the respective metals, the formula of the copper compound being Cu_2C_2.

According to Mosso and Ottolengui (*Rendiconti Della R. Academia dei Lincei.*, 1896) acetylene gas is an active poison, causing death in the dog in about one minute through respiratory failure, and always producing a fatal result when present in the air in more than 20 per cent. Rosemann (*A. E. P. P.*, xxxvi, 1895) asserts that its toxic properties are very feeble, and that it has no action upon hemoglobin.

In Moissan's experiments from 40 to 79 per cent. of the vapor was necessary in the air breathed before toxic manifestations were produced (*C. R. A. S.*, cxxi), while Oliver found that no symptoms were caused so long as even a moderate amount of atmospheric air was maintained with the vapor, and when the animal was made to breathe pure acetylene gas the symptoms were very similar to, if not identical with, those of asphyxiation. (*B. M. J.*, 1898, i.)

Calcium carbide, CaC_2, from which acetylene is made, is prepared by melting a mixture of powdered lime and coke dust in an electrical furnace. It is a grayish-brown, dense substance having a crystalline metallic fracture and the specific gravity of 2.26. It evolves a peculiar odor when exposed to the atmosphere, due to the action of moisture which causes partial decomposition with the production of acetylene. When exposed to the air, it lumps, it becomes coated with a layer of calcium hydroxide, which to a great extent protects the interior of the lumps from further deterioration. Calcium carbide is not inflammable and one pound, if pure, yields 5.9 cubic feet of acetylene gas at 18° C. (64.4° F.). The production of calcium carbide throughout the world in 1909 was 280,000 tons, of which the United States and Canada produced 45,000 tons.

Acetylphenylhydrazin. $C_6H_5.(NH)_2.C_2H_3O$. —This substance, first introduced into medicine in an impure form, under the name of *pyrodin,* has since been used in an alleged pure condition under the name of *hydracetin.* It is chemically closely allied to acetanilid, which possesses only one imido-group, (NH); it is, as indicated by its name, hydrazin in which hydrogen atoms are replaced by phenyl and acetyl. It is made by heating together phenylhydrazin and glacial acetic acid, and purifying the product by recrystallization. It forms colorless, inodorous crystals, melting at 128.5° C. (263° F.), soluble in fifty parts of water and readily soluble in alcohol. Guttmann (*Pr. M. W.*, 1889) demonstrated that this substance is a powerful poison, seven and a half grains (0.5 Gm.) being sufficient to kill a rabbit, with a remarkable destruction of the red blood cells. He found it a powerful antipyretic, in *doses* of from one and a half to two and a half grains (0.096–0.16 Gm.) but believes it to be a very dangerous remedy on account of its action on the blood. Externally he considered it to be safe, and allied to pyrogallic acid in its influence upon *skin diseases;* but Basch (*L. L.*, 1890) has seen very violent poisoning from the use of a 10 per cent. ointment, without benefit to the *psoriasis.* On the other hand, Lemoine (*B. M.*, 1889) finds it, in *doses* of three-fourths of a grain (0.048 Gm.), a valuable remedy in the treatment of *hectic fever of phthisis,* reducing the temperature and checking night sweats. When the *dose* of two and a half grains (0.16 Gm.) per day is exceeded, violent symptoms (cyanosis) are apt to be produced.

Acetylsalicyl Amide. *Ethrisin. Arthrisin.*—This occurs as white crystals which are soluble in alcohol and acetic acid. It is intended for the treatment of *rheumatism.*

Achillea. *U. S.* 1870.—The flowering tops of *Achillea Millefolium* L. *Milfoil,* or *yarrow* is a perennial herb, very common both in Europe and America. It is from a foot to eighteen inches in height, and is specifically distinguished by its doubly pinnate, downy, minutely divided leaves, with linear, dentate, mucronate divisions, from which it derived the name of milfoil, by its furrowed stem and involucre, and by its dense

corymbs of whitish flowers, which appear throughout the summer, from June to September. The whole herb has medicinal properties. *Achillea nobilis*, L., and *A. moschata* Jacq., or *Iva* of Europe, are sometimes used as substitutes for *A. Millefolium*.

Both the flowers and leaves of *A. Millefolium* have an agreeable, though feeble, aromatic odor, which continues after drying, and a bitterish, astringent, pungent taste. The aromatic properties are strongest in the flowers, the astringency in the leaves. The plant contains a blue volatile oil, tannin, and a peculiar principle, *achillein*, which was discovered by Zanon. (*Ann. Ch. Ph.*, lviii, 21.) As analyzed by von Planta (*Ann. Ch. Ph.*, clv, 1870) its formula is $C_{20}H_{38}N_2O_{15}$. It occurs in a brownish-red mass of a strongly bitter taste, soluble in water, more feebly in alcohol, and not at all in ether. *Achilleic acid*, also discovered by Zanon, is affirmed by Hlasiwetz to be identical with aconitic acid. The oil, which may be obtained separately by distillation with water, has a beautiful azure-blue color, and the peculiar flavor of milfoil. Schimmel & Co. (*Ber. d. Chem. Ges.*, 1894, p. 50) found its most important constituent to be *cineol*, $C_{10}H_{18}O$. The high boiling blue portion is probably identical with the *azulein* of chamomile oil. *Ivaïn*, $C_{24}H_{42}O_5$, has also been isolated; it occurs as a dark-yellow resinous mass, insoluble in water, readily soluble in alcohol, and producing an intensely bitter solution.

The active principles of the drug are extracted both by water and alcohol. Milfoil is a mild aromatic sudorific tonic and astringent. Pappi states that *achillein* given in divided doses up to from thirty to seventy-five grains (2–5 Gm.) causes marked irregularity of the pulse. The infusion is sometimes used in acute *suppression of the menses*. The *dose* of achillea is thirty to sixty grains (1.9–3.9 Gm.); the volatile oil has been used in doses of ten to fifteen minims (0.6–1.0 mil).

Acitrin.—The ethyl ester of 2-phenyl-cinchoninic acid, $C_9NH_5(C_6H_5)COOC_2H_5$, is found in commerce under the name of *acitrin*. It occurs as a pale yellow, crystalline powder, without odor or taste. It is very slightly soluble in water, but more readily in alcohol or ether. It melts at 61° C. (141.8° F.).

It is used in the treatment of *gouty* and *rheumatic* affections in the same manner as phenyl-cinchonic acid. The *dose* is eight to fifteen grains (0.5–1 Gm.).

Acocanthera.—The Wa Nyika, the Wa Gyriama, and the Wa Kamba tribes of Eastern Africa, and the natives of Obok on the Gulf of Aden, prepare vegetable arrow poisons probably from different species of plants, although the names *wabayo* and *ouabaïo* seem to have been used as synonyms by missionaries and others sending the extract to Europe.

The botanical sources of these arrow poisons are uncertain. It is certain that several species of the apocynaceous genus *Acocanthera* are used for arrow poisons by the natives of Africa. Of the four principal species, *A. schimperi* B. and H. is found abundantly in the highlands of Abyssinia and throughout a great portion of Eastern Africa; *A. deflersii* Schwf., which resembles the last-named species closely, but, according to Schweinfurth, differs in that its flowers are larger, sweet-smelling and pure white, has been found in the neighborhood of Yemen; *A. ouabaïo* Arnaud is a native of Somaliland, and *A. venenata* Don, of South Africa. For details, see *A. de S.*, cvii, p. 1162; abs. in *J. P. C.*, 1889, p. 245. From *Acocanthera abyssinica* is prepared *Shashi-poison* of German Eastern Africa.

In 1882 Arnaud obtained from an unidentified species of the genus Acocanthera (which he named provisionally *A. Ouabaïo*), a crystalline glucoside, and in 1893 Lewin separated from the *Acocanthera Deflersii* an amorphous glucoside.

Owing to the imperfect identification of the plants from which the principles have been obtained, there has been much confusion in the names which have been applied to the principles which various investigators have separated from these arrow poisons. According to Lewin (*B. K. W.*, 1906, p. 1583), there are two glucosides found in the various species of acocanthera, one of which is crystalline, and the other amorphous. The amorphous substance, or, as it is generally known, *amorphous ouabain*, corresponds to the *abyssinin* of Briege (*A. I. P. T.*, 1903), and the *carissin* prepared by Bancroft from the *Carissa ovata* R. Br. (Fam. *Apocynaceæ*), an Australian plant. The *acocantherin* of Frazer he regards as identical with the crystalline ouabain of Arnaud, and probably is isomeric with the amorphous variety. It is generally conceded that the crystalline ouabain is chemically identical with the glucoside discovered by Thoms in the *Strophanthus gratus* (see page 1068). Its action seems to be precisely the same as that of strophanthus. Ouabain was apparently first employed clinically by Stadelmann (*B. K. W.*, 1906, vol. xliii, p. 1586), and has more recently been used by others with more or less success in the treatment of various forms of *cardiac weakness*. Stadelmann used an amorphous glucoside prepared by Merck from the wood of the *Acocanthera Schimperi*, in *doses* of from one three-hundredth to one two-hundredth of a grain (0.0002–0.0003 Gm.) three times a day.

Acoine. $HCl.C{=}NC_6H_4O(C_2H_5)$, $NHC_6H_4O(CH_3)$, $NHC_6H_4O(CH_3)$.

Di-para-anisyl-mono-phenetyl-guanidine-hydrochloride.—A white, crystalline powder, melting point 176° C. (348.8° F.), and soluble in water (six parts to one hundred). It is incompatible with iodine or alkaline iodides. Acoine was introduced as a local anesthetic by Trolldenier. (*Th. M.*, xiii; also *Zeit. T. M.*, 1901.) It has been specially used by ophthalmologists in a 1 per cent. aqueous solution, stronger solutions being very irritant or even corrosive. It is not absorbed through a normal conjunctiva, but when the epithelial covering is destroyed, or when the drug is injected into the sub-conjunctival tissues, it is said to act more powerfully than cocaine, and to be specially efficacious in the relief of deep-seated ocular pains. It is also actively antiseptic, the 1 per cent. solution remaining free from bacteria. Acoine has also been used with asserted excellent results in dentistry and in operations upon the nose. For dental purposes a 2 per cent. solution is preferred. One per cent. of common salt should be added to hypodermic solutions, which are preferably made with distilled water.

Acrolein. *Acrylic Aldehyde. Allyl aldehyde.* C_3H_4O. $CH_2{=}CH.CHO$.—Acrolein, a decomposition product of glycerin or glycerides, is a fluid which emits an intensely pungent odor, is soluble in two or three parts of water, and boils at 52.5° C. (126.5° F.). It is asserted by E. Koch and G. Fuchs (*Cb. B.*, 1899, xxvi) to be a valuable bactericide, but its exceedingly disagreeable odor and

tendency to undergo decomposition have prevented its coming into use. It is the cause of the irritating vapors given off when glycerin or fats are heated in air to the point of decomposition.

Actæa. *Actæa spicata*, L. *Baneberry. Herb Christopher. Radix Christophorianæ. Racine de Saint Christophe*, Fr. *Christophswurz, Wolfswurz*, G.—This is a perennial herbaceous plant (Fam. *Ranunculaceæ*) growing in the woods of mountainous regions from Japan to Central Europe as well as in Siberia. Its dark-brown, bitterish, somewhat acrid root resembles that of *Helleborus niger*, for which it is said to be occasionally substituted. It is an active emeto-purgative, capable of producing, when in overdose, dangerous effects. There are two American species which probably have medicinal properties similar to those of *A. spicata*,—namely, *A. alba* (L.) Mill., or *white cohosh*, and *A. rubra* (Ait.) Willd., or *red cohosh*, distinguished by the color of their berries. *Actæa racemosa* was the former name of the official *Cimicifuga racemosa*. (*Proc. A. Ph. A.*, 1858.)

Actinium.—This was discovered in 1899 in uranium pitch blend by De Bierne, and is asserted to be identical with the *anemium* of Giesel (De Bierne, *C. R. A. S.*, 1899, cxxix and 1904, cxxxix, p. 538). It has been used by Czerny and Caan (*M. M. W.*, 1911, p. 1801) in the treatment of various forms of *cancer*. They inject intramuscularly from one-sixth to two grains of actinium suspended in normal salt solution (0.01–0.12 Gm.).

It occurs commercially as a brownish-red powder, insoluble in water, but soluble in strong nitric or hydrochloric acids.

Actinomeris. *Verbesina helianthoides* Michx. (*Actinomeris helianthoides* Nutt.) (Fam. *Compositæ.*)—At one time known as *Gravel Weed, Diabetes Weed*, now known as *Sunflower Crownbeard*. It is a perennial herb growing in the thickets and on dry prairies from Ohio and Missouri to Texas and Georgia. The root is said to be largely used in Upper Georgia in *dropsy* and *chronic cystitis*. *Dose* of infusion (one ounce to a pint), one fluidounce (30 mils).

Adalin. *N. N. R.* 1917.—This remedy, which is *bromine-di-ethyl-acetyl-carbamid*, $C(C_2H_5)_2BrCONHCONH_2$, is a white, crystalline powder with a slightly bitter taste, almost insoluble in water. It melts at 116° C. (240.8° F.). According to Impens (*Ther. Geg.*, 1912, p. 158), it is slowly absorbed and partially broken up in the system, being eliminated both as an inorganic bromide and in the original form. It was introduced into medicine with the idea that it would combine the sedative effects of bromine with the narcotic action of the aliphatic series. The dose of bromine which is administered under this circumstance is, however, so small that it seems improbable that it could seriously modify the action of the drug, and the conclusions of Takeda (*A. I. P. T.*, 1911, xxi, p. 203), that its effects are due to the whole molecule, are probably correct. It is used in medicine as a somnifacient, nerve sedative and analgesic. As a hypnotic it is frequently useful in the milder forms of *sleeplessness*, but in severe cases is uncertain in its effects. The somnifacient dose should be from fifteen to twenty grains (1–1.3 Gm.). Adalin differs markedly from most of the other aliphatic narcotics in that it possesses distinct analgesic properties and is useful in *neuralgia* and various forms of neurotic *pains*. As a general nerve sedative it has been employed in *neurasthenia, hysteria, epilepsy, whooping cough*, and a host of other conditions accompanied with hyper-irritability of the central nervous system. The *dose* in these conditions is ordinarily from five to fifteen grains (0.2–0.9 Gm.). According to Finck (*Med. Klin.*, 1910, p. 1860), it may be given safely up to forty-five grains (2.9 Gm.) in the twenty-four hours.

Adamon.—Adamon is the dibromo-dihydro cinnamic acid ester of borneol. It is used as a sedative in *neurasthenia, hysteria* and other conditions of nervous erethism. According to Oppenheim (*D. M. W.*, 1913, p. 1103), it is especially valuable as an anaphrodisiac in *nymphomania*. *Dose*, eight to twelve grains (0.5–0.7 Gm.).

Adansonia. *Adansonia digitata*, L. *Baobab.*—A tree of enormous magnitude, belonging to *Bombaceæ*. It is a native of Africa, extending quite through that continent from Senegal to Abyssinia, and has been introduced into the West Indies. The leaves and bark of this tree abound in mucilage, and have little odor or taste. By the Africans the leaves are used as a diaphoretic, and the subacid pulp of the fruit in *dysentery*. Under the name of *cream-of-tartar tree* various trees have been described. Their fruits contain, or have been supposed to contain, potassium bitartrate. The most important of these is the *Adansonia Gregorii* F. Muell., of North Australia. Another cream-of-tartar fruit is yielded by a tree of South Africa, which, according to E. M. Holmes, is probably the *Adansonia madagascariensis* Baillon. This fruit has been examined by E. J. Millard (*P. J.*, April, 1890), who found that it contains no cream of tartar at all. It is probably identical with a cream-of-tartar fruit examined by F. L. Slocum. (*A. J. P.*, 1880). Heckel and Schlagdenhauffen (*Nouv. Rem.*, xxi, 487) have found in the fruit of the *Adansonia digitata* as much as 2 per cent. of free tartaric acid and 12 per cent. of potassium bitartrate. Duchassaing, of Guadeloupe, West Indies, and Pierre, of France, commended the bark of *A. digitata* highly as an antiperiodic. (*A. G. M.*, 3e sér., xxiii, 535.) It is said to be acceptable to the stomach, and to produce no other observable physiological effect than increase of appetite, increased perspiration, and perhaps diminished frequency of pulse. An ounce may be boiled in a pint and a half of water to a pint, and the whole taken in a day. (*J. P. C.*, 3e sér., xiii, 412 and 421.)

Adenanthera. *Adenanthera pavonina* L. *Zangavara.*—Rochebrune (*Toxicologie Africaine*) states that he has obtained from this plant a crystalline principle which resembles in its activity physostigmine, but does not affect the muscles.

Adenia. *Adenia venenata* Troost.—A climbing passion-flower of Africa, said by Schweinfurth to be used as a vesicant. (*P. J.*, March, 1874.) The *Adenium hongkii* is employed by the natives of the Soudan as an ordeal poison. Perrott and LePrince (*P. J.*, 1910, lxxxiv, p. 82) have separated an active principle which is neither glucosidal nor alkaloidal, and which has a strophanthin-like effect.

Adhatoda. *Br. Add.* 1900. (Fam. *Acanthaceæ.*)—The fresh and dried leaves of *Adhatoda Vasica* Nees. (*Justicia Adhatoda*, L.) "The fresh leaves are four or six inches (about ten to fifteen centimeters) long and about an inch and a half (nearly four centimeters) broad, they are opposite lanceolate, entire short petiolate, taper-pointed, smooth on both sides. The dried leaves are of a dull brownish-green color which becomes much

lighter when the leaves are powdered. They have a strong characteristic tea-like odor and a bitter taste." *Br. Add.*, 1900.

The leaves are stated to contain an alkaloid, *vasicine*, and an organic acid, *adhatodic acid* (see *Pharmacog. Indica*, vol. iii). Vasicine, isolated by Hooper, is soluble in water, sparingly in benzin and carbon disulphide, readily soluble in ether and chloroform. The claim is made for it that it exerts a powerful toxic influence upon lower forms of vegetable and animal life, and is not poisonous to the higher animals. The leaves are stated to be actively poisonous to frogs and are considerably used in India as an expectorant and antispasmodic, especially in the treatment of *asthma*. The Br. Add. recognized the *liquid extract* (*Extractum Adhatodæ Liquidum*, Br. Add., 1900), made with alcohol and given in doses of from twenty to sixty minims (1.3–3.75 mils); the freshly *expressed juice* (*Succus Adhatodæ*, Br. Add., 1900), *dose*, from one to four fluidrachms (3.75–15.0 mils); the *tincture* (*Tinctura Adhatodæ*, Br. Add., 1900), *dose*, from one-half to one fluidrachm (1.8–3.75 mils).

Adiantum. *Maidenhair.*—Tradition has attributed to various species of this genus of ferns valuable properties in chronic pulmonic *catarrhs*. *A. pedatum*, L., of America, *A. Capillus-Veneris*, L., of Europe, *A. lunulatum* Burm., of India, are the most important of these alleged medicinal species. The European species is sometimes employed on the Continent as an emmenagogue under the name of *polytrichi*, *polytrichon*, or *kalliphyllon*, and is given in the form of infusion, sweetened with sugar or honey, and a syrup prepared from it is said to be popular in France under the name of *sirop de capillaire*, and is official in the French Codex.

Adonis. *N. F. IV. Vernal Pheasant's Eye. Sommerteufelsauge*, G.—It is official in the N. F. IV, in which it is defined as "the dried, overground portion of *Adonis vernalis* Linné (Fam. *Ranunculaceæ*), without the presence of more than 5 per cent. of foreign matter." This ranunculaceous plant of Northern Europe and Asia has long been used as an abortifacient, while its rhizome sometimes occurs in commercial black hellebore as an adulteration. Linderos examined the leaves and found in them 10 per cent. of *aconitic acid*. (*Ann. Ch. Ph.*, 1876, 340.) Cervello, in 1882, obtained from the plant a glucoside, to which he gave the name of *adonidin*. For improved method of preparation, see *P. J.*, vol. xvi, 145, and *A. J. P.*, 1887, 609. This glucoside occurs in the form of a somewhat hygroscopic, canary-yellow powder of an intensely bitter taste; soluble in water, alcohol, and in amyl alcohol; insoluble in anhydrous ether, chloroform, oil of turpentine, or petroleum benzin. Its reaction is neutral. It reduces Fehling's solution, if previously heated with a few drops of hydrochloric acid. It exists in small quantities in all portions of the plant. For further details as to reactions, see *P. J.*, xv, 145. Podwyssotzki found commercial samples of adonidin to be mixtures of the active principle with other constituents of the plant. He gives the name of *picroadonidin* to the active principle, which he describes as an amorphous glucoside having an excessively bitter taste, possessing the properties of a cardiac poison in the highest degree, and being easily soluble in water and alcohol and entirely soluble in ether. (*P. J.*, xix, 1888, 346.) According to Fuckelman, confirmed by Mercier (*Nouv. Rem.*, 1914), commercial adonidin is a mixture of a neutral body with a hemolytic acid, *adonic acid*. Cervello states (*A. E. P. P.*, xv) that adonidin exists also in the *Adonis cupaniana* of Southern Europe, and F. Borgiotti affirms the value of *A. æstivalis*, L., in heart affections. (*D. M. Ztg.*, Aug., 1888.) Tahara asserts that the glucoside of *Adonis autumnalis*, L., is distinct, and calls it *adonin* ($C_{24}H_{40}O_9$) (*Ber. d. Chem. Ges.*, xxiv), while Y. Inoko (*A. E. P. P.*, xxviii) affirms that the glucoside of *A. amurensis* of Japan is also peculiar, and assigns to it the formula $C_{30}H_{40}O_9$, allied to adonidin, but much less powerful.

Merck has described an additional crystalline principle, which fuses at 102° C. (216° F.), is very soluble in water and warm alcohol, and crystallizes in clear needle-like prisms. It has a neutral reaction, does not reduce Fehling's solution, and is not colored brown by alkalies. Its analysis seems to indicate a formula $C_5H_{12}O_5$, and Merck considers that it is a hitherto undescribed pentatomic alcohol, and calls it *adonite*. Whether it be identical with the *adonidulcite* announced in a preliminary communication by Podwyssotzki shortly before his death, Merck is not able to state, as no details of fusing point, formula, or chemical reactions were given by the former. (*M. Bull.*, Jan., 1893.) E. Fischer (*Ber. d. Chem. Ges.*, 1893, 633) confirms the formula $C_5H_{12}O_5$ given by Merck, as well as the statement that it is a pentatomic alcohol; by oxidation with sodium hypobromite it is changed into *ribose*, $C_5H_{10}O_5$, which treated with sodium amalgam again yields adonite.

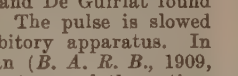
The National Formulary description is as follows: "Glabrous, with the exception of the younger portions, which may be slightly grayish-puberulent; stems from 15 to 50 cm. in length, thick, but soft and weak; shining, simple or branched, the branches mostly from near the base and similar to the main stem; naked below, except for some scale-like leaf-vestiges, densely leafy above; leaves from 2 to 4 cm. in length and two-thirds or more as broad, pinnately divided into several segments, the larger of which are again divided, the ultimate segments being narrowly linear, and acute; flowers terminal, yellow but usually drying to a cream color, from 3 to 6 cm. in breadth; sepals five, green or grayish-puberulent, more than half the length of the petals, oblong, obtuse, finely nerved; petals from five to twenty, oblong, obtuse, finely nerved; stamens indefinite; pistils numerous, in fruit forming an ovoid, obtuse, dense head of ovoid akenes, which are tipped with the very small, persistent styles. Odor faint; taste bitterish, afterward somewhat acrid. The powdered drug is grayish-green and, when examined under the microscope, exhibits numerous fragments of pith parenchyma, the cells with few simple pores, up to 0.05 mm. in width and 0.25 mm. in length; groups of long narrow sclerenchyma fibers, mostly with lignified walls from 0.005 to 0.007 mm. in thickness and having a few rounded or oblique simple pores; tracheæ spiral or with bordered pores and up to 0.017 mm. in width; epidermal cells from the stem and petiole, elongated in surface view and with elliptical stomata, the latter about 0.064 mm. in length; fragments of the epidermal tissue from the lamina of the leaf, composed of finely striated cells with wavy, vertical walls; associated with broadly elliptical stomata, the latter up to 0.047 mm. in length; brownish colored fragments from the scales at the base of the stem, composed of elongated cells with somewhat rounded ends and yellowish-brown walls; starch grains

and calcium oxalate crystals few or absent. Adonis yields not more than 12 per cent. of ash."

Adonidin belongs physiologically to the digitalis group. Although in Hare's experiments (*T. G.*, 1886) the frog's heart was arrested in diastole. Cervello (*A. E. P. P.*, xv) and De Guirlat found that the arrest is systolic. The pulse is slowed by stimulation of the inhibitory apparatus. In the experiments of Henrijean (*B. A. R. B.*, 1909, xxiii, p. 363) in the early stages of the action, electrical stimulation of the pneumogastric nerve produced an unwonted degree of retardation of the pulse rate, which would indicate an increased excitability of the peripheral ends of the nerves. All investigators are in accord that the slowing of the pulse is to a large extent abolished by section of the vagi, so that the inhibitory influence must be largely also of central origin. There occurs also a pronounced rise of the blood pressure, which, according to Hare, is due partly to a stimulant action upon the heart, and partly to an effect upon the vasomotor mechanism. In the more exact experiments of Henrijean, vaso-constriction appeared only late in adonidin poisoning. After large toxic doses, the heart becomes irregular, and the blood pressure falls. According to Kakowski (*A. I. P. T.*, xv, p. 21), adonidin differs from most of the other digitalis group in that it dilates the coronary arteries, while most of these drugs produce constriction.

Adonis vernalis was introduced as a cardiac tonic by Bubnow in 1879. Clinical experience confirms the conclusion of the pharmacologist, that it resembles digitalis in its action, and is a useful agent in the treatment of chronic *heart disease*. The advantages which have been claimed for it are, that it is more prompt in its action, and that it manifests less cumulative tendency than digitalis, but it appears to be less certain in its effect. Bechterew asserts that it is a useful remedy in *epilepsy* when used in conjunction with the bromides. The *dose* of adonis vernalis is from two to ten grains (0.12–0.6 Gm.), which may be given in the form of an infusion. The glucoside adonidin may be given in doses of one-twelfth to one-fourth of a grain (0.005–0.015 Gm.).

Æsculus. *Horse-chestnut.*—Chestnut (*Æsculus Hippocastanum*, L.) said to have been originally a native of Asia, but introduced about the middle of the sixteenth century into Europe, whence it has spread to this country. It is to this species that this article especially applies, though it is probable that any medicinal properties which the tree may have are shared by the other species of the genus. The seed or nut abounds in starch, but its bitter, disagreeable taste has prevented its general use as a food, although as long ago as 1856 starch was made from it in France, and recently a pleasant and nutritious article of diet is said to have been prepared by removing its bitter principle by means of alcohol. For analysis of the oil it contains, see Stillesen, *Proc. A. Ph. A.*, 1909, lvii, p. 201. In the leaves Rochleder found *quercitrin*, and a bitter principle, *esculin* (*æsculin*); and in the capsules of the fruit a peculiar acid, *capsulæsic acid* (*J. P. C.*, May, 1859; Aug., 1860). (For Rochleder's method of extracting esculin, see *U. S. D.*, 18th edition; for a second process, see *A. J. P.*, xliv, 400.) Esculin is in shining, white, prismatic crystals, inodorous, bitter, but slightly soluble in cold water, more soluble in boiling water, and very readily so in boiling alcohol and in alkaline solutions. Its solution, which is fluorescent, is precipitated by lead subacetate, and its formula, according to Schiff, is $C_{15}H_{16}O_9 + 1\frac{1}{2}H_2O$. When treated with dilute sulphuric acid, it is converted into grape sugar and a substance called *esculetin*, $C_9H_6O_4$, which is now known to be a *dioxycoumarin*,



Tannin is found in all parts of the tree, including the leaves as well as the bark and fruit. According to Rochleder, when pure, it is white and soluble in water, alcohol, and ether; becomes red by the absorption of oxygen; colors ferric salts green, but violet on the addition of a little alkali; fluorescent when it is in alkaline solution; in concentrated solution is precipitated, at least partially, by sulphuric, hydrochloric, and metaphosphoric acids, but not by acetic acid, and forms also, with potassium and sodium sulphites and ammonium sulphide, precipitates which are readily dissolved by dilute acetic acid. (*J. P. C.*, Jan., 1868, 72.)

The powdered kernel of the nut is a sternutatory. The extract of the wood has been used in dyeing silk black. The fixed oil, extracted from the kernels by ether, has been employed in France as a topical remedy in *rheumatism;* and the bark as an antiperiodic in doses of half an ounce (16 Gm.) in the twenty-four hours, given in the form of decoction. The flowers are stated to contain quercitrin. In the United States a decoction of the leaves is popularly employed for *whooping cough*, and to the seeds themselves, when "carried in the pocket of the patient," is attributed the marvellous property of curing *hemorrhoids*, *rheumatism*, etc. Esculin has also been administered in *malarial disorders*, in fifteen-grain (1 Gm.) *doses* repeated once during the intermissions. (*Ann. Thér.*, 1859, 1860.) The glucoside esculin has the property, like other fluorescent substances, of absorbing ultra violet rays which are then gradually given off. Because of these properties, it is used on the one hand, as a protective against the effects of sunlight and on the other as a means of continuing the effect of heliotherapy. Thus Freund has found it useful not only against *sunburn*, but as a prophylactic against *snow blindness* (*Zeit. f. Neuere Physikal. Med.*, 1908, ii), and Graham (*L. L.*, 1905, ii, p. 1769) recommends it in the Finsen light treatment of *lupus vulgaris* and similar conditions. For this purpose he injected five minims (0.3 mil) of a 2 or 3 per cent. solution immediately beneath the skin in the region to be treated by the light. Under the name of *zeozon* and *ultra-zeozon* there are upon the market pastes whose exact compositions are not stated but which are claimed to contain oxyderivatives of esculin.

The fruit of the *Æsculus pavia* L., or *Red Buckeye* of the Southern United States, is said to be an active convulsant. E. C. Batchelor (*A. J. P.*, xlv, 144) found in the cotyledons of the seeds about 2½ per cent. of a peculiar glucoside. *Æsculus glabra* Willd., the *Ohio Buckeye*, is asserted to be useful in *portal congestion*. (*N. P.*, ii, 21.)

Æthusa. *Fool's Parsley. Æthusa Cynapium*, L. (Fam. *Umbelliferæ.*)—A fetid herb naturalized from Europe and growing in waste places or cultivated grounds in the northern United States and Canada. In 1859, Walz stated that the fruit of the *Æthusa Cynapium* contains a volatile base similar to coniine. This statement has been confirmed by Power and Tutin (*J. Am. C. S.*, 1905, xxvii) who recovered, besides various inert mat-

ters, about one forty-thousandth of 1 per cent. of the volatile alkaloid. This plant has been variously attributed with poisonous properties, but Harley (*P. J.*, 1880, xi, p. 43) denies any noxious quality, and, in the experiments of Power and Tutin, the extract from five hundred grammes of the dry herb caused in a small dog, vomiting and salivation, but the animal entirely recovered.

Afridol. *Sodium hydroxymercuric toluylate. N. N. R.* 1916. $C_6H_3(CH_3)(COONa)HgOH$ 2:3:1. —This is an odorless, tasteless white powder, difficultly soluble in neutral or acid media, but soluble in ammoniacal solution containing ammonium chloride. It is said to be of value for rendering parts of the body antiseptic for surgical operations. It has also been recommended in the treatment of parasitic skin diseases, *acne*, *sycosis*, etc., the afridol soap being proposed for this purpose.

Agaric. *Agaricus Albus. White Agaric. Larch Agaric. Touchwood. Spunk. Tinder. Fungus purgatif*, Fr. *Larchenschwamm*, G.—It is defined in the National Formulary IV as "the dried fruit body of the fungus *Polyporus officinalis* Fries (Fam. *Polyporaceæ*) [growing on one or more species of *Pinus* Linné, *Larix* Adanson, and *Picea* Link (Fam. *Pinaceæ*)], deprived of its outer rind, and without the presence of more than 10 per cent. of foreign matter." The term Agaric is more properly applied, however, to the fungi of the genus Agaricus, but most medical writers and the N. F. limit it to the fungus from *Polyporus officinalis* Fries (*Boletus laricis* Jacquin; *B. purgans* Persoon), which is found upon the old trunks of the European larch and upon *Larix sibirica* Ledebour, of Asia. The same species is found on various coniferous trees in some of the western United States and British Columbia. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but, as found in commerce, it is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. That which is most esteemed is said to be brought from Siberia; but it is probably produced wherever the European larch grows. It is described in the N. F. as in "light, fibrous, somewhat spongy pieces of irregular shape; grayish-white to pale brown externally; yellowish and resinous internally; fracture tough, fibrous; friable but difficult to powder. The powdered drug, examined under the microscope, shows numerous non-septate, narrow, mycelial threads and many cubical crystals of calcium oxalate from 0.01 to 0.02 mm. in diameter. It yields to boiling alcohol not less than 50 per cent. of a resinous extract. Agaric yields not more than 2 per cent. of a white ash, rich in phosphates." *N. F.* Wm. M. McPheeters (*St. L. M. S. J.*, x, 421) found a specimen brought from the Rocky Mountains decidedly cathartic in *doses* of twenty-four grains (1.6 Gm.).

Agaric has a sweetish, very bitter taste. It owes its medicinal virtues to *Agaric acid* (*N. N. R.*, 1916), which is also called *laricic* and *agaricinic acid*. This is a tribasic acid, $C_{19}H_{36}OH(CO OH)_3 + 1\frac{1}{2}H_2O$, occurring as an odorless, tasteless, micro-crystalline powder, melting at 141.5° C. (286.5° F.). According to J. Schmieder, agaric contains a small amount of soft resin, $C_{15}H_{20}O_4$, extracted with petroleum benzin, and from 4 to 6 per cent. of a fatty body, which is made up of (1) *agaricol*, $C_{10}H_{16}O$, fusing at 223° C. (433.4° F.); (2) *phytosterin*, $C_{26}H_{44}O$; (3) solid hydrocarbons, $C_{23}H_{46}$ and $C_{29}H_{54}$; (4) cetyl alcohol, $C_{16}H_{33}.OH$; (5) a liquid aromatic alcohol, $C_9H_{18}O$; (6) a fatty acid, $C_{14}H_{24}O_2$; and (7) ricinoleic acid, $C_{18}H_{34}O_3$. (Schmidt, *Lehrbuch der Pharm. Chem.*, ii, 3te Auf., 1528.) J. D. Riedel has produced two phenetidides of agaric acid, for which antipyretic and anhidrotic properties are claimed. (*Ph. Ztg.*, xlvii.) *Sodium, Lithium* and *Bismuth agaricinates* have been prepared and introduced into medicine.

According to Hoffmeister (*A. E. P. P.*, 1889, xxv, p. 189), in a moderate dose, agaric acid has no effect upon the system, except to paralyze the nerves of the sweat glands. When given in very large doses, it produced primary excitation of the medulla, followed by paralysis, increasing at first the blood pressure and the respiratory rate, which was followed by diminishing activity in both. The large doses also acted as an irritant to the stomach and intestine, causing vomiting and purging. The depressant action shown on the sweat glands was not shared by the other glands of the body. McCartney (*J. P. Ex. T.*, 1917, x, 83) offers the remarkable theory that its antihydrolic action is due to spasm of the muscular layer of the skin. The most important use of agaric is in the treatment of the *colliquative sweats* of wasting conditions, such as *phthisis*. Its value in these conditions has been abundantly confirmed by clinical experience. Aside from the solanaceous drugs, it is probably the most reliable remedy that we possess for this purpose. Rosenbaum has found the *fluid extract of agaric* (*Med. Klin.*, 1906) of service in various catarrhal conditions of the alimentary tract, even in *intestinal tuberculosis*.

Under the name of *agaricin* are marketed preparations containing the active *agaric acid*, with larger or smaller amount of impurities. The *dose* of the pure principle is from one-sixth to one-half of a grain (0.01–0.03 Gm.).

Thoerner obtained from *Agaricus atramentosus* crystalline, dark-brown scales, which he believed to be *dioxykinon*. (*Ber. d. Chem. Ges.*, 1878, 533.) According to T. L. Phipson, *Agaricus ruber* contains a rose-red coloring matter, *ruberin*, which appears bright-blue by transmitted light; being soluble in water, it is washed out of the head of the fungus by a heavy fall of rain. Ether extracts from the fungus a yellowish-white alkaloid, *agarythrine*, which has a bitter, afterwards burning taste, somewhat like aconitine; its chloride is soluble, but the sulphate insoluble in water, the latter dissolving in alcohol; it dissolves in nitric acid with red color, and is colored red by chlorinated lime and afterwards bleached. On agitating the solution of the alkaloid with ether, it is oxidized by the air to a red coloring matter, which is probably the cause of the red color of the surface of the fungus. (*Chem. News*, 1882, 199.) An agaric growing on the *Larix leptolepis*, and used in Japan as a sacred medicine under the name of *Toboshi* or *Eburiko*, has been found by Y. Inoko to contain agaric acid. (*Sei-I-Kwai*, April, 1891.)

Fungus chirurgorum. Boletus chirurgorum, Wundschwamm, G.—*Surgeon's agaric* is the product of *Polyporus fomentarius* (L.) Fries, which is found upon the oak and beech trees of Europe. It is shaped somewhat like the horse's foot, with a diameter of from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon

the bark of the tree, without any supporting footstalk. On the upper surface it is smooth, but marked with circular ridges of different colors, more or less brown or blackish; on the under surface, it is whitish or yellowish, and full of small pores; internally it is fibrous, tough, and of a tawny-brown color. It is composed of short tubular fibers compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting the fungus is August or September. It has neither taste nor odor. Among its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, nitrogenous matter also in small quantity, potassium chloride, and calcium sulphate, and in its ashes are found iron, and calcium and magnesium phosphate. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting *hemorrhage*, being applied with pressure. *P. ignarius* (L.) Fries and *P. marginatus* Fries yield similar products.

When prepared polyporus (so-called agaric) is steeped in a solution of nitre, and afterwards dried, it constitutes *spunk*, *punk*, or *tinder*, the *amadou* of the French, which occurs in flat pieces, of a consistence somewhat like that of very soft, rotten buckskin leather, of a brownish-yellow color, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared also from various other species of *Polyporus*, as *P. ungulatus*, *P. ribis*, etc.

Agathin. $C_6H_5.N(CH_3).N : CH.C_6H_4.OH$. *Salicyl-α-methyl-phenyl-hydrazine.*—This is obtained by the reaction of salicylic aldehyde upon α-methyl-phenyl-hydrazin. It is a yellowish crystalline substance, without odor or taste, is insoluble in water, soluble in alcohol and ether and melts at 74° C. (165.2° F.). It was proposed as a remedy by Israel Roos, and is said by E. Rosenbaum to act like salicylic acid. Although excellent results (see *D. M. Ztg.*, 1892, Nos. 50, 93) have been claimed for it in *neuralgia* and *rheumatism*, without unpleasant effects other than headache, in trials by H. C. Wood it did not seem serviceable. *Dose*, from five to ten grains (0.3–0.65 Gm.).

Agave. *Agave americana*, L. *American Agave. American Aloe. Maguey.* (Fam. *Amaryllidaceæ.*)—An evergreen succulent plant, indigenous to Florida, Mexico, and other parts of tropical America, and largely cultivated, chiefly for hedges, in the south of Europe, especially in Spain. Although the *Agave americana* is the best known form, botanists have described fifty species of the genus, which are indigenous to South America and the southern portions of North America, and many of which contribute to the economic products produced in that country from the agave plant. The number of these products is very great. *Sisal grass* or *sisal hemp* and *Tampico hemp*, also known as *Pita hemp* or *Pita fiber*, are the most important of the various fibers obtained from the agave leaves, though a number of other forms are locally known in Mexico. From a number of species of *Agave*, are produced in Mexico, large quantities of fermented liquors, known as *pulque*, and distilled liquors known as *mescal* or *tequila*. All of the pulque agaves have thick leaves. When they are about to bloom the central bud is cut out, leaving a large cavity into which the sap (*aguamiel* or *honey water*) exudes rapidly. At first clear green, yellowish or whitish, this sap soon by fermentation becomes milky and acquires a cider-like taste or, if the process is allowed to go on, is rapidly converted into vinegar. *Pulque* is said to contain about 7 per cent. of alcohol, and is very largely used as a beverage by the Mexicans, but its odor and taste are disagreeable to unaccustomed palates. The juice has in it an optically inactive reducing sugar, *agavose*, $C_{12}H_{22}O_{11}$. The leaves and roots and stocks of the agave contain saponin and are used in Mexico in the place of soap. The fresh juice is said to be laxative, diuretic, and emmenagogue, and in doses of two fluidounces (60 mils) useful in *scurvy*. The leaves are said to be used as counter-irritants, and Lenoble has found in them an acrid volatile oil. (*J. P. C.*, xv.) *Agave Gum* has been compared to gum arabic, but differs in containing a much larger proportion of lime, and in being only partially soluble in water, the soluble portions resembling pure gum, but the larger insoluble portions having all the characteristics of bassorin.

Agave virginica, L., which grows in our Southern States, is known in South Carolina by the name of *rattlesnake's master*, has a very bitter root, which is used, in the form of tincture, in *colic*.

Agelæa. *Agelæa Lamarckii* Planch.—Under the name of *Cephan-Mahi*, *Soandrou*, *Vahé-mainti*, this African plant is used as an anti-blenorrhagic. According to Rochebrune (*Toxicologie Africaine*), it contains a poisonous glucoside, *agelætoxine*.

Ageratum. *Ageratum conyzoides* L. (Fam. *Compositæ*), a Brazilian plant commonly known in cultivation as ageratum, is said by Barker Smith (*C. D.*, May 15, 1876) to be used as an emmenagogue.

Agrimonia. *Agrimonia Eupatoria*, L. *Common Agrimony. Herba Agrimoniæ. Aigremoine, Eupatoire des Grecs*, Fr. *Odermœning, Leberklette*, G. (Fam. *Roscaceæ.*)—This species of agrimony is a perennial herb, indigenous to Europe, and while somewhat resembling one or more species of Agrimonia growing in the United States, it differs, according to Britton, markedly in foliage and fruit from any of our species. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. A volatile oil may be obtained from the plant by distillation. Agrimony is a mild astringent and alterative. It also contains a bitter principle. *Dose*, one drachm (3.9 Gm.) or more. (See 16th ed., U. S. D.)

Ailanthus. *Ailanthus glandulosa* Desf. *Tree of Heaven. Chinese Sumach. Tree of the gods. Ailanto. Götterbaum*, G.—This well-known shade-tree, belonging to the Fam. *Simarubaceæ* in its general aspect and the character of its foliage, appears like a gigantic sumach, and was at one time considered to be a Rhus. In France it is cultivated for the sake of its leaves, upon which the Chinese silkworm is fed, and is known by the name of *Japan varnish* (*vernis de Japon*), from its having been mistaken for the true Japan varnish tree, which is a species of Sumach. (*P. J.*, vii, 370.) The powdered bark is of a greenish-yellow color, possesses a strong, narcotic, nauseating odor, in the fresh condition, and has a strongly bitter taste. When chewed, it is said to produce a general uneasiness, a sense of increasing weakness,

vertigo, cold sweats, with shivering and a sensation of nausea. It has been found to contain lignin, chlorophyll, a yellow coloring principle, a gelatinous substance (pectin), quassiin, an odorous resin, traces of a volatile oil, a nitrogenous fatty matter, and several salts. F. H. Davis detected traces of a crystallizable organic acid, but no alkaloid or glucoside. (*A. J. P.*, 1885, 600.) By the action of alcohol, there is obtained from the bark an *oleoresin* which has the consistence of tar, a very dark greenish-brown color, and in a high degree the odor and taste of the bark. Hetet found the bark to produce in dogs copious stools and the discharge of worms. The resin purged, but rarely acted as an anthelmintic. The powdered bark has been used successfully against the *tapeworm*. In China the bark is very popular as a remedy in *dysentery* and other *bowel complaints*. (*A. J. P.*, 1874, 276; *P. J.*, vii, 372.) *Dose*, from seven to thirty grains (0.45–2.0 Gm.). The oleoresin produces the same effect in a somewhat smaller dose, and keeps better than the bark, which loses its powers with age. (*J. P. C.*, March, 1859, 163.)

In India the bark of the *Ailanthus excelsa* Roxb. is used as a bitter tonic. It occurs in rough, dirty-green pieces. Narayan Daji found in it a bitter uncrystallizable principle and a bitter nitrogenous acid, *ailanthic acid*, to which he attributes medicinal virtues. (*P. J.*, Aug., 1870, Oct., 1876, June, 1877.) This acid is not used medicinally in this country.

Air. *Liquid Air.*—This substance is produced commercially for the manufacture of oxygen and nitrogen. In its manufacture air is subjected to a pressure of 200 atmospheres, then cooled by a salt and ice mixture, and suddenly allowed to expand to 20 atmospheres. This compression and expansion is repeated until the temperature reaches −189° C. (−308.2° F.), when most of the air liquefies. It is difficult to transport, owing to its tendency to return to gas, and is therefore usually used near the point of manufacture. It is usually a milky liquid, from the presence of solid carbon dioxide, but may be freed from CO_2 and becomes transparent and of a slightly bluish color. Substances such as rubber, meat, eggs, mercury, etc., when plunged into it are frozen in a few moments. When applied to the skin it freezes the parts and may be utilized as a local anesthetic for minor surgical operations. Taylor and McKenna (*Lancet*, 1909, ii, p. 1774) have used liquid air with good results in the treatment of *lupus erythematosus* and also for the destruction of *nævi*. The method of applying it is to wrap a piece of absorbent cotton around the end of a stick about ten inches long. This is immersed for a moment in liquid air and then pressed firmly against the part to be treated.

Ajowan. *Ajava. Ajwan.*—The ripe fruit of *Carum copticum* Benth. et Hook. (*Carum Ajowan* Benth. et Hook., *Ptychotis Ajowan* D. C.), an annual of the Fam. *Umbelliferæ*. It is cultivated in India, Egypt, Persia and Afghanistan. The fruits resemble those of parsley, but are distinguished by their odor. They yield 3 to 4 per cent. of volatile oil which contains from 45 to 55 per cent. of thymol. This oil is official in the B. P. (see *Oleum Ajowan*). The fruits also contain from 25 to 32 per cent. of a fixed oil and from 15 to 17 per cent. of protein, making them a very good cattle food. They are used in the form of an extract and water, viz.: *Extractum Ptychotis Liquidum* P.I. and *Aqua Ptychotis* P.I. The water known as *Omum water* is used in India in the treatment of *cholera*. The *dose* of the *Fluidextract of ajowan* is ten to thirty minims (0.6–2.0 mils).

Ajuga.—Of this genus *A. chamæpitys* (L.), or *Ground Pine; A. reptans*, L., *Mountain Bugle*, or *Common Bugle;* and *A. pyramidalis*, L., all of them European species, the last naturalized in America, have been used in medicine, and are probably mild astringents and tonics. The ground pine is said to contain a volatile oil, and has been used to some extent in *amenorrhea* and in various forms of *rheumatism*, in *doses* of from one to two drachms (3.9–7.7 Gm.). *Ajuga Iva*, L., of Sardinia, is said to be a depressomotor, an active bactericide, and an antiperiodic. (*A. I. B.*, xxxiv.)

Akazga. *Boundou. Quai. Ikaga. Icaya.*—An ordeal poison, largely used in a district on the west coast of Africa, extending far into the interior, north and south of the equator. The precise botanical character of the plant is unknown, but it is thought to belong to one of the *Loganiaceæ*. Thomas R. Fraser found in the plant an alkaloid, *akazgine*. The alcoholic extract or the alkaloid acts on the system similarly to nux vomica. (For further description, see *U. S. D.*, 19th ed., p. 1373 and also *A. J. P.*, March, 1867.)

Alangine.—This alkaloid, according to Scheriff, occurs in the bark of the stem and root of *Alangium Lamarckii* Thwaites (Fam. *Coruaceæ*), a shrub indigenous to the tropical forests of India and Burma. It is very bitter, soluble in alcohol, chloroform, and acetic ether, but insoluble in water. In small doses it acts as a febrifuge; in *doses* of fifty grains (3.2 Gm.) it is emetic.

Alanin (Alpha). $CH_3CH(NH_2)COOH$. *Propionic Glycocoll. Alpha-aminopropionic acid.*—Prepared from aldehyde ammonia by hydrocyanic and hydrochloric acid and forms white crystals that are soluble in alcohol and water. It is used as the basis for the preparation of alanin compounds.

Alanin Mercury. *Hydrargyri Amidopropionas. Mercury Amidopropionate.*—Lucca asserts that this compound may be administered internally or subcutaneously, in *doses* of from one-twelfth to one-sixth of a grain (0.005–0.01 Gm.). To prepare "alanin mercury," crystallized amidopropionic acid is dissolved in water, heated to boiling, and mercury added as long as it is dissolved. The filtrate is rapidly evaporated, and the compound then separates in white, crystalline needles.

Alantol. (*Pinguin.*) $C_{10}H_{16}O$.—Prepared by distillation from the root of *Inula Helenium* (*Elecampane*). It is a yellowish to a brownish-yellow liquid with a taste and odor similar to peppermint. It is insoluble in water and soluble in the immiscible solvents. It has been used in place of turpentine in *pulmonary tuberculosis*. *Dose*, one-sixth minim (0.01 mil) 10 times daily in pill or powder form.

Alboferrin. *Alboferine.*—A light-brown, odorless, non-hygroscopic and permanent powder consisting of a phospho-albumin preparation of iron, freely dissolving in cold water and possessing a slightly saline taste. Its composition is stated to be as follows: albumin, 90.14 per cent.; iron, 0.68 per cent.; phosphorus, 0.32 per cent.; amido nitrogen, 0.13 per cent., and mineral substances, 9.5 per cent. This preparation has been recommended by a number of German clinicians as a good ferruginous tonic in *anemia, scrofulosis, rickets*, and other diseased conditions. *Dose*, for

a child, fifteen to forty-five grâins (1–3 Gm.); for adults, forty-five to seventy-five grains (3–5 Gm.) a day.

Alchemilla. *Alchemilla vulgaris*, L. *Lady's Mantle.* (Fam. *Rosaceæ.*)—This astringent, bitterish perennial European herb was formerly employed in *diarrhea.* By the ancients it was highly esteemed; extraordinary powers were ascribed to it by the alchemists. (*P. J.*, 1885, 791.)

Alcornoque.—For an account of this bark, which has long since fallen into entire neglect, see 16th edition *U. S. D.*, p. 1545.

Aldehydes.—Aldehyde is a generic term that applies to a class of bodies holding an intermediate position between the alcohols and the acids derived from the former by oxidation. The word itself was coined from the Latin *al*cohol *dehyd*rogenatum, meaning alcohol deprived of hydrogen. They are generally prepared by the oxidation, by chromic acid, of the respective alcohols.

Anisic Aldehyde. Anisaldehyde.—Prepared from anethol by oxidation. Formula $C_6H_4(O.CH_3).CHO$.—A colorless liquid with an aromatic odor. Soluble in alcohol and ether. Boiling point 245°–246° C. (473°–474.8° F.). Sp. gr. 1.126 at 15° C. (59° F.). It is used in admixture with other odorous substances in perfumery, the addition of other odors being necessary to bring out the agreeable hawthorn odor of the aldehyde.

Butylic Aldehyde. (*Iso-butyryl aldehyde.*) $(CH_3)_2CH.CHO$.—A transparent, colorless, highly refractive liquid. Sp. gr. 0.797. Miscible with water and alcohol and possessing a pungent odor.

Ethyl Aldehyde. CH_3CHO. *Acetic Aldehyde. Ethylic Aldehyde. Aldehyde, Acetaldehyde. Aldéhyde acetique* (*vinique*), Fr.—This substance is commonly given the name "Aldehyde," which, being a generic name, is misleading and indefinite. The following formula for its preparation is given: One part of ethyl alcohol, of sp. gr. 0.842, and 1 part of potassium dichromate are introduced into a large tubulated retort, and 1⅓ parts of sulphuric acid dropped in through the tubulure. Sufficient heat is evolved to start the distillation, but heat must be applied towards the end. The distillate is slightly contaminated with acetic acid. If the aldehyde be desired pure, the distillate is to be mixed with twice its volume of ether, surrounded with cold water, and dry ammoniacal gas passed in to saturation. Aldehyde-ammonia crystallizes out. This is to be decomposed in a retort by a mixture of 3 parts of sulphuric acid and 4 parts of water, and the distillate rectified and dried by contact with calcium chloride. Aldehyde is a colorless, mobile, inflammable liquid, having a decidedly pungent, ethereal, and suffocating odor. Its sp. gr. is 0.790, and boiling point 22° C. (71.6° F.). It mixes in all proportions with water, alcohol, and ether, and is rapidly converted into acetic acid on exposure to the air, through absorption of oxygen. It possesses very marked anti-putrescent properties, meat being preserved for months by its 2 per cent. aqueous solution. The intoxication caused by it in animals is characterized by a very great loss of sensibility. It appears to paralyze the vagi, although its cardiac action is comparatively feeble. Upon the respiration it exerts a most powerful influence, in small doses quickening it, in large doses depressing it. The temperature is much diminished. Applied locally aldehyde is very irritating. (*M. T. G.*, Sept., 1875.)

Heptoic Aldehyde. Oenanthol. Heptanal. $C_6H_{13}CHO$.—A highly refractive liquid, colorless and possessing an agreeable aromatic odor. It is prepared from castor oil by heating and fractional distillation, and is soluble in alcohol and ether and slowly in water. It is used in perfumery and as the basis of the preparation of other odorous aldehyde compounds.

Iodaldehyde may be made by mixing together iodine, iodic acid, and a solution of aldehyde and separating by adding water. (See paper by P. Chautard, *P. J.*, 1886, 224.)

Paracuminic Aldehyde. Cuminol. Cumyl Hydride. $(C_6H_4)(CH_3)_2.CH.CHO$.—A yellowish oily fluid with a persistent strong odor and an acid burning taste. It is one of the constituents of Roman chamomile. It is soluble in alcohol and ether and has a sp. gr. of .9382 at 0° C. (32° F.).

Propylic Aldehyde. Propionic Aldehyde. $CH_3CH_2.CHO$.—A colorless liquid with a suffocating odor, soluble in water, and boiling at 48° C. (118.4° F.). It is claimed to be a powerful antiseptic and an effective preservative.

Valeric Aldehyde. Isovaleric aldehyde. $(CH_3)_2CH.CH_2.COCO$.—A colorless liquid with a pungent, apple-like odor. It is miscible in all proportions with alcohol and ether, boils at 92° C. (197.6° F.), and has a specific gravity of 0.804 at 15° C. (59° F.). It is used commercially as an artificial flavoring agent and in the art of perfumery. It was also proposed at one time as a hypnotic and sedative, but was later on abandoned.

A condensation product of Aldehyde is known as "*Aldol,*" $CH_3CH(OH)CH_2CHO$, and is exploited as a hypnotic and sedative. Like formaldehyde it will, on spontaneous evaporation, leave a solid residue of *Paradol*, a polymeric substance.

Aletris. *N. F. IV. Unicorn Root. Star Grass. Aletris farinosa* L. *Blazing Star. Mealy Starwort. Colic Root. Ague Root. Alétris farineux. Unicorn Root true*, Fr. *Mehlige Aletris*, G. (Fam. *Liliaceæ.*)—It is described in the N. F. as "the dried rhizome and roots of *Aletris farinosa* Linné (Fam. *Liliaceæ*). Rhizome horizontal or slightly oblique, nearly cylindrical or laterally compressed above, from 2 to 4 cm. in length and from 5 to 12 mm. in diameter; externally grayish-brown, upper portion with circular stem scars from 3 to 7 mm. in diameter and with numerous leaf bases, the sides and lower portion with numerous tough, wiry, whitish or reddish-brown roots which are more or less flexuose and provided with short branches; fracture short; internally light brown, cortex from 1 to 2 mm. in thickness, central cylinder with numerous twisted and branching fibro-vascular bundles. Odor slight, acetous; taste sweetish, somewhat bitter. Examined microscopically, the greater part of the drug is found to consist of parenchyma cells filled with spherical or ellipsoidal starch grains from 0.008 to 0.016 mm. in diameter. Some of the parenchyma cells contain raphides, the latter being from 0.025 to 0.045 mm. in length. The tracheæ are reticulate or provided with simple pores and around these are several layers of lignified cells with thick walls and simple, large oblique pores. The endodermis is composed of several layers of thick-walled and closely-lamellated cells of a deep yellow color and the cortex is readily separated. Aletris yields not more than 16 per cent. of ash." *N. F.* An indigenous perennial plant, the leaves of which spring immediately from the rhizome, and spread on the ground in the form of a star. This drug is often contaminated with other drugs collected by mistake for it, being most fre-

quently confused with *Helonias* species. The bitterness is extracted by alcohol, and the tincture becomes turbid upon the addition of water. The decoction is moderately bitter, but much less so than the tincture. It affords no precipitate with the salts of iron. (Bigelow.) In small doses of about ten grains (0.65 Gm.), it appears to be a simple, bitter tonic. In very large doses, it is said to be cathartic and emetic. It has been employed, with asserted benefit, in *colic, dropsy* and *chronic rheumatism. Aletrin,* a resinoid, is prepared by exhausting the drug with alcohol and evaporating the percolate to dryness, treating with water, and drying the residue; it is asserted to be a *uterine stimulant* in *doses* of from one to two grains (0.065–0.13 Gm.). *Dose,* of aletris, thirty grains (1.9 Gm.).

Aleudrin.—*Dichloroisopropyl alcohol carbamate,* $CH_2Cl.CHO(CONH_2).CH_2Cl$, a white, odorless, crystalline powder; melting at 82° C. (179.6° F.); sparingly soluble in water; readily dissolved by organic solvents.

According to Maass (*D. M. W.*, 1912, p. 1232), aleudrin exercises on the lower animals an hypnotic effect without influence upon temperature, circulation, or respiration. According to Burchard (*D. M. W.*, 1913, p. 1044), it has a marked analgesic action and is a useful remedy in *neuralgias* and other painful neuroses. It has also been used as a general sedative in various conditions of nervous excitation, such as *hysteria, chorea, mania,* etc. In full doses it has an hypnotic action and may be used in *insomnia.* The *dose* is from eight to twenty-five grains (0.5–1.5 Gm.).

Algarobilla, the pod of *Cæsalpinia brevifolia,* (Clos.) Benth. (Fam. *Leguminosæ*), a drug containing over 60 per cent. of tannin and a quantity of *ellagic acid,* is obtained from Chili. (Gehe's Report, *N. R.*, 1878, 332; *J. Chem. S.*, 1891, 918.)

Alisma. *Alisma Plantago-aquatica,* L. *Water Plantain. Plantain d'eau. Pain de grenouilles,* Fr. *Froschlöffel, Wasserwegerich,* G. (Fam. *Alismaceæ.*)—A perennial herbaceous plant, common to Asia, Europe, and the United States. The root has, when fresh, an odor like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It contains a pungent volatile oil and an acrid resin, to which all its virtues must be ascribed. The Calmucks in Russia are said to use it for food. The *leaves* are rubefacient, and will sometimes even blister. They have been recommended in *gravel* and *cystitis. Dose,* a drachm (3.9 Gm.).

Alkanet. *Anchusæ Radix. Alkanna Root, Alkanet Root, Orcanette,* Fr. *Spanish Bugloss. Alkannawurzel,* G.—This is the root of *Alkanna tinctoria* L., or *dyers' alkanet,* an herbaceous perennial plant, of the Fam. *Boraginaceæ,* growing in the Grecian Archipelago and the south of Europe, where it is cultivated. See E. M. Holmes, *P. J.*, 1897, p. 61. For an account of Syrian alkanet and allied plants, see *Proc. A. Ph. A.*, 1896, 565. Alkanet, as found in commerce, is in pieces 7 to 10 cm. long, and from 5 to 15 mm. thick, somewhat twisted, consisting of a dark-red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the center, and composed of numerous distinct, slender, cohering fibers. As it comes to us it is usually much decayed internally, very light, and of a loose, almost spongy texture. The fresh root has a faint odor, and a bitterish, astringent taste; but when dried it is nearly inodorous and insipid. Its coloring principle, which abounds mostly in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a deep red color, but is insoluble in water. It may be obtained by first exhausting the root with water, and then treating it with a weak solution of potassium or sodium carbonate, from which the coloring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses acid properties, forming with the alkalies and earths neutral compounds, which are of a blue color, and soluble in alcohol and ether. Its weak acid character resembles that of alizarin, to which it is chemically related, as when distilled with zinc dust it yields *methyl-anthracene.* It has also received the names of *anchusin* and *alkannin.* The *anchusin* has been extracted and studied by C. J. S. Thompson. (*A. J. P.*, 1886, 409.) He finds it to vary in amount between 5.25 and 6.02 per cent. It is red, resin-like, insoluble in water, soluble in oils, alcohol, chloroform, and ether, and with a rich deep blue color in alkali hydroxides, the color changing again to crimson on addition of an acid. According to A. Gawalowski, the red coloring matter of alkanet root consists of two distinct bodies, the one turning blue, the other green by the action of alkalies. The first of these, *alkannic acid,* is extracted by ether and alcohol. The second, *anchusic acid,* is obtained by extraction with benzene. Both form characteristic colored salts. (*Ph. Ztg.*, 1902, 817.) Alkanet is somewhat astringent, and was formerly used in several diseases; but it is now employed exclusively for coloring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. The best way to use it with this object in view is to suspend the alkanet, after tying it in a piece of flannel, in the melted fat. A fine color is obtained by previously washing the alkanet with water and then thoroughly drying it before suspending it in the fat or oil. It is said also to be used in the preparation of spurious *port wine.* The *Oleum Hypericum,* formerly much used under that title or the name *Red Oil,* consisted of fixed oil colored with alkanet.

Allamanda.—*Allamanda cathartica,* L., is a shrub of the Fam. *Apocynaceæ,* growing in Porto Rico, the extract of whose bark is said to be an excellent hydragogue cathartic, in *doses* of from one to two grains (0.065–0.13 Gm.).

Alliaria. *Alliaria officinalis* Andrz. [*Sisymbrium Alliaria,* Scop. *Erysimum Alliaria,* L. *Alliaria Alliaria* (L.) Brit.] *Hedge Garlic.*—A perennial European herb, a native also of Northern Asia, and naturalized from Canada to Virginia, having an alliaceous odor when rubbed, and a bitterish, somewhat acrid taste. When eaten it communicates its odor to the breath. Wertheim obtained from the root a volatile oil, apparently identical with that of mustard. (*Ann. Ch. Ph.*, liii, 52.) The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and are used as external applications in *gangrenous affections,* and to promote *suppuration.*

Allophanic Acid. *Acidum Allophanicum.* $NH_2.CO.NH.CO.OH$.—This is a *urea-carbonic acid,* but occurs only in the form of salts and esters, as at the moment of liberation the acid splits into urea and carbonic acid gas. Its best known derivative is its amide, called *biuret.* Apparently it exercises no influence on the system of itself, but according to Overlach (*B. K. W.*, 1908, p. 1403) is valuable because it has the power of forming compounds with a number of substances of unpleasant taste and penetrating odor, and rendering them

much less disagreeable. For instance, santalol unites with allophanic acid to form a tasteless, dry, crystalline powder (having the composition $NH_2.CO.NH.COOC_{15}H_{23}$). The same is true of castor oil and of creosote.

The combination of santalol and the allophanic acid has been used in the treatment of *gonorrhea* under the name of *Allosan;* it represents about 72 per cent. of santalol. The *dose* is fifteen to thirty grains (1–2 Gm.).

Almatein.—This proprietary article is a condensation product of formaldehyde with hematoxylin and is given the concrete formula $CH_2O_2.(C_{16}H_{12}O_5)_2.CH_2$. It is a bright red, light powder, odorless and tasteless, insoluble in water, but soluble in dilute alkalies, alcohol or glycerin. Astalfoni (*Press. Med.*, 1908) finds that it has a powerful antiseptic action and is non-poisonous. It passes through the system unchanged, and is split up by the alkaline intestinal juices, with the slow liberation of formaldehyde, and is employed as an intestinal disinfectant. It has been used also as a dusting powder on *wounds* (Werndorff, *M. M. W.*, 1909), also dissolved in glycerin as an injection in cold *abscesses*. One drawback to its use is its staining powers. The *dose* for internal administration is from five to fifteen grains (0.3–0.9 Gm.).

Alnus. *Alder.*—Of this genus of small trees or bushes, *A. glutinosa* (L.) Medic., or *European Alder, Black Alder; A. rugosa* (Du Roi) K. Koch (*A. serrulata* Willd.), or *American Alder; A. incana* (L.) Willd., or *Tag Alder*, are tonic and astringent, and have been used in intermittent fever, the bark being the part employed. *A. glutinosa* has been used for dyeing and also for tanning. According to Eitner, the bark contains from 16 to 20 per cent. of tannic acid. The tannic acid, however, appears to differ from that of galls and oak bark, as, according to Stenhouse, it does not yield glucose when acted on by sulphuric acid. (*P. J.*, Dec., 1861.) F. Dreykorn and E. Reichardt, however, state that it is resolved by sulphuric acid into *alnine red* and sugar. (*A. J. P.*, xlii, 403.)

Alpha-naphthol. $C_{10}H_7OH$.—A coal tar constituent obtained in colorless prisms or powder of a disagreeable taste. It is sparingly soluble in water, but more soluble in alcohol and ether. It melts at 94° C. (201.2° F.), and boils at 278°–280° C. (532°–536° F.). In antiseptic action it is about equivalent to its isomer, beta-naphthol. It is used internally as an antiferment in five grain (0.3 Gm.) doses; in *typhoid fever* thirty to sixty grains (2–4 Gm.) a day. Externally it has been used in a 10 to 20 per cent. oily solution in *erysipelas, scarlet fever* and *smallpox*, as well as in various *skin diseases*. According to Maximovitch, alpha-naphthol has the same action upon pathogenetic germs as has beta-naphthol, having the superiority over the latter compound, however, of being less poisonous to the higher animals in proportion to its germicidal power. It may be used in the same strength of solution and the same dose as beta-naphthol. Alpha-naphthol has been proposed as a test for sugar in urine. Posner and Epenstein have studied the action of the test, and considered it to be free from many of the objections raised against other tests for sugar. The test depends upon the fact that a solution of sugar, in the presence of pure concentrated sulphuric acid and a solution of alpha-naphthol, gives a violet-colored reaction, due, according to Udransky, to the separation of furfurol. This reaction occurs not only with sugars, but with all carbohydrates and with certain albuminoids; hence *the urine must be free from albumin.* The test is said to be extremely sensitive, showing one-hundredth of one per cent. of sugar. The urine must always be previously diluted. *Winkler's test* for hydrochloric acid in the stomach is performed as follows: 5 Gm. of alpha-naphthol are dissolved in 100 mils of alcohol, to which is added from 0.5 to 1.0 Gm. of grape sugar. A mixture of the filtered gastric juice is then evaporated with a few drops of the reagent in a porcelain dish on a water bath; if free hydrochloric acid be present, a bluish-violet marginal zone will appear and rapidly become inky black. Various compounds of naphthol have been proposed in medicine. The substance recommended by Polaillon, under the name of *microcidin*, as being ten times more powerful than phenol and less toxic than beta-naphthol, is said to be *sodium naphthol.* (Helbing's *Mod. Mat. Med.*, 79.)

Alphol.—*Salicylic Ester of Alpha-naphthol, Alpha-naphthol salicylate,* $C_6H_4\begin{cases}OH\\COOC_{10}H_7\end{cases}$, is obtained by reaction between salicylic acid and alpha-naphthol. It is a white, crystalline powder, melting at 83° C. (181.4° F.). Soluble in alcohol, ether, and fixed oils; insoluble in water, decomposed in the alkaline secretions of the intestinal tract into alpha-naphthol and salicylic acid. It is incompatible with alkalies and with ferric compounds. Used as an antiseptic and antirheumatic. *Dose,* eight to fifteen grains (0.5–1.0 Gm.).

Alphozone. *Succinic Dioxide. N. N. R.* 1916. $(COOH.CH_2CH_2CO)_2O_2$.—This powerful oxidizing agent occurs as a fluffy, white, crystalline powder, the crystals being small, irregular plates. It is fairly soluble in water and alcohol, sparingly so in ether and insoluble in chloroform and benzene. It is devoid of odor and deteriorates slightly on exposure to air. It is employed for the germicidal and antiseptic properties of its oxygen, being used both externally and internally. Unlike hydrogen peroxide it does not effervesce on contact with pus. A 1 to 1000 solution in water is generally used externally.

Aluminum.—Under the name of *escalin*, a mixture of two parts of the finely powdered metallic aluminum with one part of glycerin has been employed by Klemperer (*Ther. Geg.*, May, 1907) as a substitute for the insoluble salts of bismuth, especially in the treatment of *gastric ulcers.* Sussman (*Ther. Geg.*, May, 1908) has also found this preparation useful in the treatment of *anal fissures.* It is marketed in the form of tablets, which when thrown into water disintegrate and yield on stirring a uniform suspension of the metal. Four of these tablets may be given at a dose, preferably on an empty stomach and repeated daily for three or four days. For description of physiological action of aluminum see p. 124.

Aluminum Acetate as well as the *subacetate* is largely employed in medicine. The deliquescent acetate may be made by the direct combination of hydrated alumina with acetic acid or by reaction between aluminum sulphate and lead acetate,

$$Al_2(SO_4)_3 + 3Pb(C_2H_3O_2)_2 = 3PbSO_4 + Al_2(C_2H_3O_2)_6.$$

The *neutral aluminum acetate* is a valuable astringent and antiseptic in *sore throat* and similar inflammatory conditions. It may be employed in the form of a gargle containing from 1 to 3 per cent. The relatively insoluble *basic acetate* is used as a dusting powder in *sweating feet*, in which it exercises both a dessicating and deodorizing influence, and in chronic *leg ulcers*,

weeping eczema, and the like. A solution containing 7.5 to 8 per cent. of *basic aluminum acetate* is official in the N. F. under the title *Liquor Alumini Subacetatis*, which is practically identical with the *Liquor Aluminii Acetici* P. G. This must not be confused with the *Liquor Alumini Acetatis* N. F. or *Burow's Solution*, which is the solution of the neutral acetate also used for much the same purposes. (See Part III). Stansburg (*Am. J. Surg.*, 1912, xxvi, p. 82) has found the N. F. solution of aluminum subacetate a valuable local application in *furunculosis*, *erysipelas* and *ivy poisoning*. He dilutes the solution with from seven to ten parts of water and saturates gauze with this solution and applies it over the diseased area.

Preparations asserted to contain the basic aluminum acetate have been introduced into therapeutics under the names of *lenicet* and *eston*. It seems probable, however, that the latter is a mixture of several aluminum salts. (See Friedlander, *Ap. Ztg.*, 1907, p. 819.) From eston is prepared two other compounds, one known as *formeston*, in which two of the acetyl radicals are replaced by formic acid, and the other *subeston*, which is a double basic acetate. These appear to be not only astringent, but also germicides of considerable power; Blasius (*Hyg. R.*, 1908, xviii, p. 941) finds that the saturated solution of eston, representing about 2 per cent., is fatal to most non-sporulating bacteria after thirty minutes' exposure.

Aluminum Acetico-tartrate. *Alsol.*—Under the name of alsol has been employed a 50 per cent. aqueous solution of the acetico-tartrate of aluminum. According to Aufrecht, this solution is a more powerful germicide than phenol. It has been found clinically valuable by Hanau and Pinner (*Med. Klin.*, 1909) wherever an antiseptic astringent is necessary, especially in the treatment of catarrhal conditions of the female genitalia. They applied it by means of gauze soaked in a 5 to 10 per cent. alsol solution. As a gargle or spray in *pharyngitis* and the like, it may be used in from 1 to 3 per cent. solution. A creamy solution of aluminum acetico-tartrate has been highly recommended by Lewitt (*Ther. Geg.*, 1910, p. 95) in the treatment of *pruritus*, *intertrigo*, *acne vulgaris*, and other skin diseases. A solution similar to alsol is recognized in the N. F. as *Liquor Alumini Acetico-tartratis* (see Part III).

Aluminum and Iron Sulphate. *Ferroso-Aluminic Sulphate. Sulphate of Aluminum and Iron.* $AlFe(SO_4)_2 + 12H_2O$.—This double salt was brought forward by Sir James Murray of Dublin, as an astringent, styptic, and vermifuge. His method of preparing it is not very clearly expressed, but it may be presumed to be formed by dissolving alumina and ferrous carbonate, both recently precipitated, in sulphuric acid, and evaporating the solution. Klauer states that it is produced in crystalline tufts when a solution of the component salts mixed with an excess of sulphuric acid is left to stand in a warm place. (*Watt's Dict.*, vol. v, 583.) Murray recommended it in *chronic dysentery*, *diarrhea*, *fluor albus*, and the *colliquative sweats* and *diarrhea* which attend *hectic fever* and *consumption*. Externally he found it a powerful styptic, useful as a gargle in *relaxation of the tonsils and uvula*, and in *salivation*, as an injection in *hemorrhages*, and as a wash for foul and flabby *ulcers*. *Dose*, from five to ten grains (0.32–0.65 Gm.), dissolved in some aromatic water.

Aluminum and Potassium Salicylate. *Alkasal. Alkasol.*—It is prepared by the combination of aluminum salicylate and potassium acetate with the use of heat. It is used for the same purposes as aluminum acetate.

Aluminum and Sodium Acetate. *Acetonal.* $Al_2(OH)_2.(C_2H_3O_2)_5Na$.—It is used as a 10 per cent. solution, and its equivalent can be prepared by dissolving 82 parts of sodium acetate in 4050 parts of liquor alumini acetatis *N. F.*

Aluminum Boroformate, $Al_2O_3B(OH)_3.H_2CO_2 + 5H_2O$, occurs in lustrous crystals, and may be prepared by introducing freshly precipitated alumina into a mixture of two parts of formic acid, one part of boric acid, and seven parts of water. The solution is evaporated and crystallized. Used as an antiseptic and astringent. (*Ph. Rund.*, 1894, 256.)

Aluminum Boro-tannate. *Cutal, Lutol.*—A brownish powder, insoluble in water, used as an astringent and disinfectant in diseases of the skin. It may be applied as an ointment or as a dusting powder.

Aluminum Boro-tartrate. *Boral.*—This is a crystalline substance, with a sweetish astringent taste, soluble in water. It is used, generally in powder form, as a local astringent in diseases of the nose and throat.

Aluminum Carbonate. $Al_2(CO_3)_2$.—This occurs in chalky white, easily pulverized, tasteless lumps. It is used as a mild antiseptic styptic in *croup*, *ocular affections*, *diarrhea*, etc. It is incompatible with acids, phosphates and lead acetate.

Aluminum Caseinate.—A yellowish-white, tasteless powder containing 5 per cent. of aluminum; insoluble in water, sparingly dissolved when macerated in saliva, and yielding aluminum to dilute acids. It was introduced by Rud. Meyer (*Ap. Ztg.*, Sept. 23, 1899, 566) as a remedy in *intestinal catarrh*, given in doses of four to five grains (0.26–0.32 Gm.). It is prepared as follows: Milk, freed from albumin by repeated heating to 62° C. (143.6° F.) and straining, and then sterilized, is precipitated with solution of aluminum subacetate (*Liquor Alumini Subacetatis*); the precipitate is washed completely with water, and after removing the water with alcohol, deprived of fat by means of ether. The product is dried at a moderate temperature, and while drying powdered.

Aluminum Chlorate, $Al(ClO_3) + 6H_2O$.—Under the name of *prophylacticum mallebrein* there has been introduced a solution which is stated to contain 25 per cent. of aluminum chlorate. It is claimed to have the property of detoxicating bacterial toxins and hence to be useful in certain infectious diseases, notably *diphtheria* and laryngeal *tuberculosis*. It is applied either as a spray or gargle in strengths of from 0.5 to 1 per cent.

Aluminum Chloride, *N. F. IV. Alumini Chloridum.*—According to the N. F., "it contains, when dried over sulphuric acid, $AlCl_3 + 6H_2O$ (241.58) corresponding to not less than 20.5 per cent. of aluminum oxide (Al_2O_3). Preserve it in well-closed containers." It "occurs as a white, or yellowish-white, deliquescent, crystalline powder; nearly odorless; taste sweetish and very astringent. One gramme dissolves in about 0.5 mil of water and in about 4 mils of alcohol at 25° C. (77° F.), also soluble in glycerin. An aqueous solution of the salt (1 in 10) is clear, and is acid to litmus. Separate portions of an aqueous solution of the salt (1 in 10) yield with silver nitrate T.S. a white curdy precipitate insoluble in nitric acid, with ammonia water a white gelatinous precipitate almost insoluble in an excess of ammonia

water, and with sodium hydroxide T.S. a white gelatinous precipitate completely soluble in an excess of the reagent. Ten mils of an aqueous solution of the salt (1 in 100), after the addition of 0.2 mil of barium chloride T.S., does not become cloudy within one minute (*sulphate*). The addition of 0.3 mil of potassium ferrocyanide T.S. to 20 mils of an aqueous solution of the salt (1 in 150) does not produce a blue coloration within one minute (*iron*). The addition of hydrogen sulphide T.S. to 10 mils of an aqueous solution of the salt (1 in 10) does not produce a white precipitate or turbidity (*zinc*). An aqueous solution of the salt does not respond to the Test for heavy metals (see *U. S. P.*, Test No. 3, Part III). An aqueous solution of the salt meets the requirements of the Test for arsenic (see *U. S. P.*, Test No. 1, Part III)."

Assay.—"Dissolve about 0.5 Gm. of the salt, previously dried in a desiccator and accurately weighed, in 100 mils of distilled water, add 1 Gm. of ammonium chloride and then precipitate the aluminum hydroxide by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it with distilled water, dry, ignite thoroughly and weigh. The weight of the aluminum oxide so obtained is not less than 20.5 per cent. of the weight of the Aluminum Chloride taken for the assay." *N. F.* Externally it is used as an astringent and antiseptic, especially in *hyperidrosis*. Internally it has been employed in locomotor ataxia in *doses* of five grains (0.3 Gm.).

Aluminum Lactate.—Perutz (*M. M. W.*, 1913, p. 1261) has used solutions of aluminum lactate in strengths of from 0.1 to 2 per cent. for its astringent effect in *chronic gonorrhea, eczema, mercurial ptyalism*, etc. He was unable to demonstrate any direct antiseptic effect, but found that in suppurative conditions it exercises a beneficial influence. Under the trade name of *Fixin* a proprietary form of this salt has been suggested as a gastro-intestinal disinfectant.

Aluminum Oleate. $Al_2(C_{18}H_{33}O_2)_6$.—A white to a yellowish tenacious mass, soluble in alcohol and ether, and is used as an antiseptic in skin diseases.

Aluminum Phenolsulphonate. *Sozal. Aluminum sulphocarbolate.* $Al_2(C_6H_4HSO_4)_6$.—This forms a reddish-white powder of slight phenol odor and astringent taste. It is soluble in water and alcohol. Merck recommends it as a substitute for iodoform, especially commendable in *cystitic* and suppurating *ulcers*.

Aluminum Salicylate. *Salumin.* $Al(C_6H_4OH\,COO)_3$.—A reddish-white powder, insoluble in water and alcohol, but soluble in dilute alkalies. It is employed in nasal and throat affections by insufflation. *Ammoniated aluminum salicylate*, a yellowish, water-soluble powder, is also used in the same manner, and in solution is employed in *catarrh* and *ozena*, as a spray.

Aluminum Silicate.—An aluminum silicate sold under the name of *neutralon* has been recommended by Rosenheim and Ehrmann (*D. M. W.*, 1910, xxxvi, p. 111) in the treatment of *hyperchlorhydria* and *gastric ulcer*. Its value depends in part upon its protective action but also partly due to the fact that it is slowly decomposed by the hydrochloric acid forming an aluminum chloride which exercises a mild astringent effect. The *dose* is from one-half to one teaspoonful (2–4 Gm.) in half a glass of water, taken an hour before meals.

Aluminum Subformate. *Aluminum formate.* $Al(HCOO)_2OH$.—Under the name of *alformin*, a solution containing about 16 per cent. of aluminum subformate has been used as an astringent and disinfectant. In *pharyngitis*, five to ten drops of this solution may be added to a glass of water and used as a gargle.

Aluminum Subgallate. *Gallal.* $Al_4(C_7H_2O_5)_3 + 4H_2O$.—Basic aluminum gallate is an amorphous, brownish powder prepared from solutions of alum and sodium gallate. It is insoluble in water, but soluble in diluted acids. It is employed, chiefly in *ozena*, as an antiseptic astringent.

Aluminum Sulphate, *N. F. IV. Aluminum Sulphas.* $Al_2(SO_4)_3 + 16H_2O = 630.67$. *Sulfate d'Alumine*, Fr. *Aluminium sulfuricum*, P. G. *Aluminium sulfat, Schwefelsaure Thonerde*, G.—A process was given in the *U. S. P.*, 1870, for the preparation of this salt, but the 1880 Committee of Revision very properly omitted the process, merely giving a description and tests for the salt. It was not admitted to the U. S. IX but was introduced into the N. F. IV. It may be manufactured by various methods (see *U. S. D.*, 19th ed., p. 124), but is now obtained chiefly as one of the by-products in the manufacture of soda from cryolite or from bauxite. The American production, chiefly from bauxite, in 1914 amounted to 164,954 short tons, and importations to 2891 tons.

It contains not less than 99.5 per cent. of $Al_2(SO_4)_3 + 16H_2O$ and is thus described (N. F. IV): "Aluminum Sulphate occurs as a white crystalline powder, shining plates, or crystalline fragments; without odor, having a sweetish and afterwards an astringent taste; permanent in the air. One gramme dissolves in 1 mil of water at 25° C. (77° F.), more soluble in boiling water, but insoluble in alcohol. When gradually heated to about 200° C. (392° F.), it loses its water of crystallization (about 45.7 per cent. of its weight). An aqueous solution of the salt (1 in 20) is acid to litmus. Separate portions of an aqueous solution of the salt (1 in 20) yield with barium chloride T.S. a white precipitate insoluble in hydrochloric acid, and with sodium hydroxide T.S. a white gelatinous precipitate which is soluble in an excess of the alkali, but which is again separated on the addition of a sufficient amount of ammonium chloride T.S. Gently heat 1 Gm. of Aluminum Sulphate with 10 mils of sodium hydroxide T.S.; the liquid does not evolve the odor of ammonia. A filtered aqueous solution of the salt (1 in 10) does not become more than faintly opalescent within five minutes after the addition of an equal volume of tenth-normal sodium thiosulphate V.S. (*free acid*). The addition of 5 drops of potassium ferrocyanide T.S. to 20 mils of an aqueous solution of the salt (1 in 150), does not produce at once a blue coloration (*iron*). An aqueous solution of the salt does not respond to the Test for heavy metals (see *U. S. P.*, Test No. 3, Part III). An aqueous solution of the salt meets the requirements of the Test for arsenic (see *U. S. P.*, Test No. 1, Part III)."

Assay.—"Dissolve about 0.5 Gm. of Aluminum Sulphate, accurately weighed, in 100 mils of distilled water, add 1 Gm. of ammonium chloride and then precipitate the aluminum hydroxide by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it with distilled water, dry, ignite thoroughly and weigh. The weight of the aluminum oxide so obtained is not less than 16.1 per cent. of the weight of the Aluminum Sulphate taken

for the assay, corresponding to not less than 99.5 per cent. of $Al_2(SO_4)_3 + 16H_2O$." *N. F. IV.*

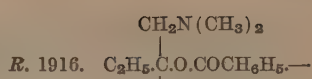
It has been employed in aqueous solution (20 grains in a fluidounce up to saturation *pro re nata*) as an antiseptic, detergent application to *foul ulcers*, and as an injection in *fetid discharges from the vagina*. Solution of aluminum sulphate is capable of dissolving a considerable quantity of recently precipitated gelatinous alumina. Such a solution, impregnated with benzoin, has been proposed by Mentel as a hemostatic, under the name of *benzoinated solution of alumina*. It resembles the *styptic liquid of Pagliari*. It is prepared by saturating with gelatinous alumina a solution made of eight ounces of aluminum sulphate dissolved in a pint of water. To the saturated solution six drachms of bruised amygdaloid benzoin are added, and the whole is kept at a temperature of about 65.5° C. (150° F.) for six hours, with occasional agitation, so that the liquid, after filtration, may have about the density 1.26. This liquid, put in a cool place for several days, so as to deposit some crystals of alum, forms the benzoinated solution, remarkable for its very sweet odor and astringent balsamic taste. Benzoinated solution of alumina, diluted in the proportion of from two to five fluidrachms to the pint of water, has been found useful as an injection in *leucorrhea*.

Aluminum Tannotartrate.—Yellowish-white lamellæ or powder, strongly astringent taste, soluble in two parts water. It has been employed as an insufflation or gargle in rhinolaryngological and other catarrhal affections. It is incompatible with iron compounds, phosphates and alkalies.

Alumnol. *Aluminum beta-naphthol-disulphonate.* $Al_2(C_{10}H_5(OH)(SO_3)_2)_3$. *Alumini naphthol sulphonas, N. N. R.* 1916.—A whitish, nonhygroscopic powder darkening slightly on exposure to air, easily soluble in cold water and very soluble in glycerin, slightly soluble in alcohol. Its aqueous solution has a slight bluish fluorescence, feeble acid reaction, and is colored blue by iron chloride. The solution of 40 per cent. is made with hot water and remains clear on cooling. Though it coagulates albumin, it is said to be dissolved in an excess of albumin, and, therefore, to be able to reach deep recesses of wounds.

It has been strongly recommended as an astringent and antiseptic in nasal, urethral, and other catarrhal inflammations. The strength of the solution employed varies from 1 per cent. in *gonorrhea* to 10 per cent. in *abscesses*. (See *B. K. W.*, 1892; *Dermatologen-Congress zu Wein*, 1892; *Th. M.*, 1892, 644.) Two to ten parts of alumnol mixed with ten parts of starch has been used by insufflation in cases of *laryngitis*. Alumnol, however, would appear to be very feeble and slowly acting as a germicide, a 1 per cent. solution requiring twenty-four hours to destroy bacilli of anthrax. As a surgical dressing from 1 to 2 per cent. solution may be used. In *infected wounds* the caustic 20 per cent. solution is employed. In diseases of the skin alumnol is used with talc or starch as a powder, or with lanolin as an ointmnet, the strength varying from 2 to 20 per cent. Its solutions are incompatible with caustic alkalies and alkaline carbonates, with albumen, gelatin solutions, soluble nitrates, silver salts, and other reducible salts. Rubbed with phenol it produces a plastic mass.

Alypin. *N. N. R.* 1916.



Alypin is 2-benzoxy-2-dimethyl-amino-methyl-1-dimethyl-amino-butane-hydrochloride. It bears a close relation to *Stovaine*, which see. Its preparation is a complicated process starting with ethyl magnesium bromide dissolved in ether and dichloracetone. It occurs as a crystalline hygroscopic powder, freely soluble in both water and alcohol, with a melting point of 169° C. (336.2° F.). Its solution will stand boiling for a period of five minutes. The *nitrate* of this same base has been also introduced, especially for the purpose of using in combination with silver salts.

Alypin has been employed as a substitute for cocaine in the production of surgical anesthesia either by local application or injecting into the subarachnoid space. It differs from cocaine in that it produces relaxation of the blood vessels, when applied locally, instead of constriction. According to Le Brocq (*B. M. J.*, March 27, 1909), alypin is about equally anesthetic to cocaine but is more highly toxic. Several cases of alypin poisoning have been reported of which at least two have ended fatally. The symptoms have been cyanosis, convulsions, stupor and arrest of respiration (see Lichtenstein, *Ther. Geg.*, 1914, xvi). Braun (*D. M. W.*, 1905) reports that it produces pronounced irritation at the point of injection, and this view has been confirmed by other investigators, especially as regards its ophthalmic use. As a local anesthetic it would, therefore, appear to have no advantages over the other preparations of its class. It has also been employed in doses of one-sixth to one-third of a grain (0.01–0.02 Gm.) for the relief of *vomiting*. As a local anesthetic it may be used in strengths of from 2 to 5 per cent. and its solutions in these strengths are stable but become moldy when further diluted. An alkali hydroxide or carbonate gives a precipitate with an aqueous solution of alypin, and mixed with calomel and dampened with alcohol it gives a black color.

Amapa Milk.—The milky sap of the bitter bark of *Plumeria Fallax* (Fam. *Apocynaceæ*), a Brazilian tree, has come into general use as a vermifuge and antimalarial, having been used and known by the natives of Brazil and South America from time immemorial. It is also used externally in the treatment of *cancerous sores*. *Dose*, for children, one minim for each year of age.

Amber. *Succinum. Ambre, Succin*, Fr. *Bernstein*, G.—Amber is a fossil resin, occurring generally in small detached masses, in alluvial deposits, in different parts of the world. According to Goefert, there are about fifty species of extinct coniferous trees of which amber represents the resinous exudation. It is found chiefly in East Prussia, either on the seashore, where it is thrown up by the Baltic, or underneath the surface. Large deposits occur in some lakes on the eastern coast of Courland, and an extensive bed of yellow amber was discovered in 1854, on sinking a well in the coal mines near Prague. The largest mass of amber yet found weighed thirteen pounds. Amber also occurs in considerable quantities near Catania, in Sicily. It is usually associated with lignite, and sometimes encloses insects and parts of plant tissues. In the United States, it was found at Cape Sable, Maryland, by Troost. In this

locality it is associated with lignite and iron pyrites. It has also been discovered in the greensand formation of Martha's Vineyard, Harrisonville, N. J., and elsewhere. The amber consumed in this country is brought from the ports of the Baltic. A mine of it is said to have been discovered near Rockwood in Australia.

It is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. It becomes negatively electric by friction. Its color is generally brownish-yellow, either light or deep, but is occasionally reddish-brown or bluish from staining with ferric phosphate. It has no taste, and is inodorous when cold, but exhales a peculiar, aromatic odor when heated. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is about 1.07. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts at 286.7° C. (548° F.), swells, and at last inflames, leaving, after combustion, a small portion of ashes. Subjected to distillation in a retort furnished with a tabulated receiver, it yields, first, a yellow acid liquor, and afterwards a thin yellowish oil, with a yellow waxy substance, which is deposited in the neck of the retort and the upper part of the receiver. This waxy substance, exhausted by cold ether of the part soluble in that menstruum, is reduced to a yellow micaceous matter, identical with the *chrysen* of Laurent. A white, crystalline substance, identical with the *idrialin* of Dumas, may be separated from the micaceous substance by boiling alcohol. Both chrysen and idrialin are hydrocarbons. (Pelletier and Walter, *J. P. C.*, v, 60.) As the distillation proceeds, a considerable quantity of combustible gas is given off, which must be allowed to escape. By continuing the heat, the oil gradually deepens in color, until, towards the end of the distillation, it becomes black and of the consistence of pitch. The oil obtained is called *oil of amber* (*Oleum Succini*), and the acid liquor is a solution of impure *succinic acid*. Repeatedly distilled from nitric acid, amber yields an acid liquor, from which, after it has been neutralized with potassium hydroxide, ether separates pure camphor. (Doepping, *J. P. C.*, vi, 168.) Borneol is also obtained by distilling to dryness powdered amber with an extremely concentrated solution of potassium hydroxide. (G. Reich, *J. P. C.*, xiii, 33.)

Tschirch (*Harze und Harzbehälter*, 278) has made within recent years a careful study of amber. He finds the main constituents to be a *succinoabietic ether of borneol*, which is extracted by prolonged treatment with alcohol, and amounts to 30 per cent. of the amber, and the *succinic ester of succinoresinol*, which is insoluble in alcohol and makes up 70 per cent. of the amber. This latter compound holds a small amount of sulphur (about 0.47 per cent.).

Amber was held in high estimation by the ancients as a medicine, but at present is never so used. The *oil of amber* is an empyreumatic product which is prepared by destructive distillation of amber. The heat requisite for the complete decomposition of amber cannot be supported by a glass retort; and, in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware retort, which may be placed immediately upon the fire; sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark-colored liquid, of a peculiar, strong, empyreumatic odor. In this state it is occasionally employed as a liniment, but for internal use it should be rectified.

The U. S. Pharmacopœia of 1870, under the name of *Oleum Succini Rectificatum*, or *Rectified Oil of Amber*, gave the following process. "Take of Oil of Amber *a pint;* Water *six pints*. Mix them in a glass retort, and distil until four pints of Water have passed with the Oil into the receiver; then separate the Oil from the Water, and keep it in a well-stopped bottle." *U. S.*, 1870.

By successive distillations oil of amber becomes thinner and more limpid, till at length, it is obtained colorless. The first portions which distil are less colored than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled. As usually found in commerce, the rectified oil is of a light yellowish-brown or amber color. As first distilled it has an amber color, sp. gr. 0.903 at 15.6° C. (60° F.), and a boiling point from 170.5°–186.1° C. (339°–367° F.). (Ebert.) When quite pure it is said to be colorless, as fluid as alcohol, of the sp. gr. 0.758 at 23.8° C. (75° F.), and to boil at 85.5° C. (186° F.). It has a strong, peculiar, unpleasant odor, and a hot acrid taste. It imparts these properties in some degree to water, without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0.847, in five parts of the sp. gr. 0.825, and in all proportions in absolute alcohol, ether, chloroform, carbon disulphide, and the fixed oils. (Ebert.) On exposure to light and air, it slowly changes in color and consistence, becoming ultimately black and solid. It appears, when quite pure, to be a hydrocarbon of the terpene class. It is said to be sometimes adulterated with oil of turpentine, which may be detected by passing hydrochloric acid gas through the suspected oil. If pure it will remain wholly liquid; while oil of turpentine, if present, will give rise to the formation of a solid compound. (*P. J.*, xiii, 292.) It was officially described as "a colorless or pale yellow, thin liquid, becoming darker and thicker by age and exposure to air, having an empyreumatic, balsamic odor, a warm, acrid taste, and a neutral or faintly acid reaction. Sp. gr. about 0.920. It is readily soluble in alcohol. When mixed with fuming nitric acid, it acquires a red color, and, after some time, is almost wholly converted into a brown, resinous mass of a peculiar musk-like odor." *U. S.*, 1870.

Rectified oil of amber is stimulant and antispasmodic, and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in *amenorrhea*, *hysteria*, and *whooping cough*. The *dose* is from five to fifteen minims (0.3–0.9 mil), diffused in some aromatic water by means of sugar and gum arabic. Externally applied the oil is rubefacient.

Ambergris. *Ambra grisea* (*cinerea*). *Ambre, Ambre gris*, Fr. *Amber, Graue Ambra*, G.—This substance, which is found floating on the sea, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus* L., or *sperm whale*. It is in roundish or amorphous pieces, usually small, but sometimes weighing as much as 50, 100, or even 200 pounds. These pieces are often composed of concentric layers. They are of various colors, usually gray, with brownish, yel-

low, and white streaks, often dark brown or blackish on the external surface. They are opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odor, is almost tasteless, softens with the warmth of the hand, melts under 100° C. (212° F.), is almost completely volatilizable by heat, and is inflammable. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterin, and denominated by Pelletier and Caventou *ambrein*. This may be obtained by treating ambergris with heated alcohol, filtering the solution, and allowing it to stand. Crystals of ambrein are deposited. It is incapable of forming soaps with the alkalies. When pure it has little or no odor. Beauregard and Gouchet believe that ambergris is a calculus composed of crystals of *ambrene* mixed with black pigment and star-coral débris. When fresh it is soft in consistence and disagreeable in odor. If kept for a year or two in air tight containers it loses its excrementitious odor and acquires the characteristic perfume for which it is valued, although its use in perfumery is more for the purpose of fixing delicate floral odors than for any odor which it contributes to the mixture itself. This change Beauregard believes is due to a microbe (*Spirillum recti physeteris*). (*C. R. A. S.*, cxxv, 254.) Ambergris is very frequently adulterated, and it then does not exhibit its ordinary odor, fusibility and volatility.

Ambergris was long regarded as a cordial and antispasmodic, somewhat analogous to musk, useful in *typhoid fevers*, and various nervous diseases. It formerly entered into many official preparations, and is still retained in some European pharmacopœias. The *French Codex* formerly directed a tincture to be prepared by macerating, for ten days, 100 parts of powdered ambergris with 1000 parts of alcohol of sp. gr. 0.864, expressing and filtering. Martin affirms that the tincture will keep better, deposit nothing, and have a more agreeable odor, if the ambergris, instead of being merely powdered in a mortar, be subjected to porphyrization, especially with the addition of washed sand. Heat, he says, should never be used in its preparation. (*J. P. C.*, 4e sér., i, 448.) It is, however, feeble as a remedy, and is chiefly used in perfumery. It is comparatively rare and very expensive, the black variety commanding a price of from $10 to $15 an ounce, while the white or gray variety costs in the neighborhood of twice that figure. *Dose*, five grains to a drachm (0.32–3.9 Gm.).

Ambrine.—The trade name for a French proprietary preparation which has been on the market for many years, but has come into prominence because of its large use during the European war in the treatment of *burns*. Similar preparations are on the market sold under the trade names *mulene, parresine, thermozine, hyperthermine,* etc. It is essentially solid paraffin with the addition of ingredients which increase its adhesiveness and plasticity. According to Leach, a similar preparation may be made by dissolving 5 drops of asphalt (asphalt varnish or *B. asphaltum*) in 1.5 mils of olive oil with the aid of heat, and incorporating the solution with 97.5 Gm. of melted paraffin (melting point 47.2° C. (117° F.). (*J. A. M. A.*, lxviii, p. 1498.) A number of other formulas have been proposed, among them paraffin, 96 per cent., and yellow wax, 4 per cent. The essential factor seems to be a melting point between 38° and 53° C. (100.4°–127.4° F.), a sterile product, sufficient strength to the film so that it may readily be lifted from the burn and a pliability which will prevent breaking if bent. In applying it to the burn the melted mixture is sprayed or painted over the area, to form a thin layer, absorbent cotton is then applied and afterwards more of the melted mixture. (Sollmann, *J. A. M. A.*, lxviii, p. 1037.)

Ambrosia. *Ambrosia trifida* L. *Ragweed, Roman Wormwood, Hog-weed, Bitter-weed, Ambrosie*, Fr. *Traubenkraut*, G. (Fam. *Compositæ.*)—This and another indigenous annual, *A. artemisiifolia* L., are deemed by the eclectics astringent and stimulant, and are given in low forms of *fever*. L. W. Schwab has found in *A. artemisiifolia* a bitter glucoside (*A. J. P.*, 1890), and Schimmel & Co. have obtained from it about 0.15 per cent. of a green volatile oil (sp. gr. 0.876). (*Schim. Rep.*, 1904, p. 96.) The pollen of this plant is also said to be one of the causes of *hay fever*. It is estimated that there are about 90,000,000 pollen grains in a gramme of ragweed pollen.

Amenyl.—Amenyl was first prepared by Freund and Heim. It is the hydrochloride of *methylhydrastimide*. It occurs as yellowish needles, melting at 227° C. (440.6° F.), soluble in hot water and alcohol. Amenyl has been used by Falk (*Th. M.*, 1909, p. 581) in the treatment of *amenorrhea*. In cases of functional amenorrhea, especially occurring during the period of puberty, he obtained good results, but in the more severe menstrual disturbances it was of little value. He believes that its action depends upon a dilatation of the blood vessels. The *dose* is one grain (0.065 Gm.).

Amidoacetal. $H_2N.CH_2CH(O.C_2H_5)_2$.—According to the experiments of A. Mallèvre (*A. Phys.*, xlix), this substance is an active poison, causing death in mammals by respiratory paralysis.

Amido-azotoluol.—Under the name of *epithermol* has been introduced a purified form of amido-azotoluol. It is asserted to have a marked power in stimulating the growth of epithelium and to be a useful application to aid the healing of skin over large *wound surfaces*, and *old ulcers*. It may be applied in the form of ointment containing 8 per cent. or in 4 per cent. alcoholic solution, or as a 10 per cent. dusting powder. Curbski (*Cb. Chir.*, 1910) has reported a case of poisoning from the use of this ointment in which the symptoms resemble those of aniline poisoning. According to Curschmann (*Th. M.*, 1911, p. 717) the acetylization of amido-azotoluol diminishes its toxicity and does not affect its therapeutic value. This preparation is on the market under the name of *azodermin*.

Amidophenols. *Derivatives of p-amidophenol*, $C_6H_4(OH)NH_2$.—In an elaborate series of experiments (*Cb. I. M.*, 1897) Treupel and Hinsberg find that derivatives from amidophenol are active as antipyretics in proportion as they are decomposed in the system, and that the decomposition is to be measured by the amount of indophenol in the urine. Among these substances is *dulcin*, called also *para-phenetolcarbamide* and *sucrol*,

$$CO\begin{cases} NH.C_6H_4.OC_2H_5 \\ NH_2 \end{cases}$$

which occurs in white, glittering, needle-like crystals, melting at from 173°–174° C. (343.4°–345.2° F.), soluble in 800 parts of cold and 55 of boiling

water, and 25 of alcohol, having a taste which is said to be two hundred times sweeter than sugar. (Dulcitol, the carbohydric alcohol related to gelatose, is sometimes assigned the name of "dulcin," and should not be confused with the amidophenol "dulcin" which possesses distinctly different characteristics.) It has been recommended as a substitute for sugar, in *diabetes*, and, on account of its solubility, to improve the flavor of castor, cod liver, or other oils. According to Treupel and Hinsberg, fifteen grains (1 Gm.) of it will reduce the temperature in fever about one degree Centigrade in the course of about three hours, and no unaltered dulcin is to be found in the urine, but indophenol.

Besides dulcin, Treupel and Hinsberg examined physiologically the following amidophenol derivatives: *Lactylamidophenolethylcarbonate, benzoylacetamidophenol, ethyldiacetamidophenol, oxyphenacetinsalicylate.*

The use of dulcin and other artificial sweetening agents as substitutes for cane sugar is prohibited by most food laws.

Aminol.—This is an antiseptic liquid, colorless, slightly turbid, and having the odor of trimethylamine. It is alkaline in reaction. Sp. gr. 1.01. It is obtained commercially from herring pickle. It is supposed to contain in each liter 1.5 Gm. calcium hydroxide, 3.5 Gm. sodium chloride, and 0.3 Gm. trimethylamine. A tablespoonful (15 mils) diluted with a fluidounce of water may be used for a lotion, gargle, or spray.

Ammi. *Ammi visnaga* Lam.—The fruit of this umbelliferous plant, indigenous in the countries around the Mediterranean, contains a crystalline principle, *kellin* (*C. R. A. S.*, August, 1879), which is said (*Union Méd.*, April, 1886) to act upon the heart and spinal cord. Mild antipyretic and antilithic properties have been attributed to the fruit.

Ammonium Anacardate. *Acid Ammonium Anacardate.*—This is the ammonium compound of beta and delta resinous acids of *Anacardium Occidentale.* (*Cashew Nut.*) It is a brownish mass, soluble in alcohol and decomposed by heat with liberation of ammonia. It is used as a hair dye and is incompatible with acids or acid salts and with lead acetate.

Ammonium Arsenate. *Ammonii Arsenas.* $(NH_4)_2HAsO_4$.—This salt is obtained in crystals by saturating a concentrated solution of arsenic acid with ammonia or ammonium carbonate, and allowing it to evaporate spontaneously. The crystals, which belong to the trimetric system, effloresce on exposure to the air, and lose half their ammonia. Its solution is alkaline. It has been used with advantage by Biett in several inveterate *diseases of the skin.* It is administered in solution, one grain of the salt in a fluidounce of distilled water; twenty to twenty-five minims (1.2–1.6 mils) of this solution may be given in divided portions in the course of the day.

The *arsenite of ammonia*, NH_4HAsO_2, a water-soluble, white powder, has also been used after the manner of and for the same purposes as the arsenate.

Ammonium Bicarbonate. *Acid Carbonate of Ammonium.* $H(NH_4)CO_3$.—This salt was brought into notice by Wm. Procter, with reference to its antacid properties. It is formed by exposure of the ordinary carbonate to the air, and is found in considerable quantities on the sides of casks in which that salt is imported, and less largely even in the bottles in which it is kept in commerce. For further information concerning this salt, see *U. S. D.*, 19th ed.

Ammonium Binoxalate. *Acid Ammonium Oxalate.* $NH_4H_2CO_4 + H_2O$.—Colorless trimetric crystals soluble in water and used solely for removing ink stains, and ecchymotic spots from the face.

Ammonium Bisulphite. NH_4HSO_3.—White crystals soluble in water and used internally in fermentative *dyspepsia* in ten to thirty grain (0.66–2.0 Gm.) doses and externally as a wash in *sore mouth* and *skin affections.* The *bisulphate*, NH_4HSO_4, colorless water-soluble crystals, has been given in fifteen to sixty grain (0.9–3.9 Gm.) doses in *gastric affections.*

Ammonium Borate. *Ammonium Metaborate.* $(NH_4HB_4O_7) + 3H_2O$.—Only the acid salt is known. By dissolving one part of boric acid in excess, in three parts of heated water of ammonia, sp. gr. 0.960, and allowing the solution to cool slowly, this salt is obtained in crystals. These are rhombic octahedrons, with truncated summits, and often truncated edges, and are semi-transparent. The taste of the salt is alkaline, and it has an alkaline reaction. On exposure, it effloresces, losing ammonia, and becoming in time the tetraborate. It is soluble in about twelve parts of water. (Gmelin, ii, 435.) Becker has used it with asserted great advantage in *stone in the bladder* and *renal colic.* Under its influence the urine becomes loaded with uric acid and the earthy phosphates. It is said also to be an excellent remedy in *chronic catarrh of the bladder.* It is believed by Becker to be the *ludus* of Paracelsus, which had a great reputation in the treatment of *urinary calculi. Dose*, ten to twenty grains (0.65–1.3 Gm.) every hour, in water sweetened with licorice. (*Journ. de Thérap. Méd.-Chir.*, Sept. 1, 1866.)

Ammonium Camphorate. *Ammonium Bicamphorate.* $NH_4HC_{10}H_{14}O_4 + 3H_2O$.—A white, crystalline powder soluble in water and possessing a sedative action on the nervous system. *Dose*, one to three grains (0.06–0.18 Gm.).

Ammonium Caseinate. *Ammonii Caseinas. Eucasinum. Casein-ammonium.*—A compound made by passing ammonia over casein until it is soluble in water, forming a nearly clear solution. In the form of a white or slightly yellow powder, almost without odor or taste. It is recommended as a dietetic, given in soups, chocolate, etc.

Ammonium Hypophosphite. *N. F. IV. Ammonii Hypophosphis.*—According to the N. F. "it contains, when dried to constant weight at 100° C. (212° F.), not less than 97.5 per cent. of $NH_4PH_2O_2$ (83.10). Preserve it in well-closed containers. It occurs in deliquescent, colorless, hexagonal plates, or as a granular powder, odorless and having a saline and bitter taste. One gramme dissolves in about 1 mil of water, and in about 20 mils of alcohol at 25° C. (77° F.); very soluble in boiling water or boiling alcohol. When heated, the salt is decomposed with the evolution of hydrogen phosphide, which is spontaneously inflammable. Dissolve 1 Gm. of Ammonium Phosphate in 20 mils of distilled water; the resulting solution is not more than slightly turbid (*calcium, aluminum*). Ten mils of an aqueous solution of the salt (1 in 100), acidulated with nitric acid, is not rendered more than slightly opalescent by silver nitrate T.S. (*chloride*). Ten mils of an aqueous solution of Ammonium Phosphate (1 in 100) mixed with 2 mils of hydrochloric acid is not rendered turbid at once by the

addition of a few drops of barium chloride T.S. (*sulphate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see *U. S. P.*, Test No. 3, Part III). An aqueous solution of the salt meets the requirements of the Test for arsenic (see *U. S. P.*, Test No. 1, Part III)." *N. F.*

Assay.—"Transfer about 1 Gm. of Ammonium Phosphate, accurately weighed, to a distilling flask, dissolve it in 300 mils of distilled water and add 25 mils of an aqueous solution of sodium hydroxide (1 in 4). Connect the flask with a small glass condenser, the lower outlet tube of which is inserted beneath the surface of 50 mils of half-normal sulphuric acid V.S., contained in a flask of about 500 mils capacity, and distil the liberated ammonia into the acid. Titrate the excess of acid with half-normal potassium hydroxide V.S., using methyl orange T.S., as an indicator and calculate the percentage of ammonia in the salt. It shows not less than 20 per cent. of NH_3. Each mil of half-normal sulphuric acid V.S. used corresponds to 0.008515 Gm. of NH_3. Each gramme of Ammonium Phosphate corresponds to not less than 23.5 mils of half-normal sulphuric acid V.S." *N. F.* It possesses the therapeutic properties of the hypophosphites with the additional stimulating property of the ammonium. It is recommended by clinicians particularly in the latter stages of *bronchitis* and *laryngitis*. *Dose*, two to five grains (0.13–0.3 Gm.) every two or three hours.

Ammonium Nitrate. *Ammonii Nitras. U. S.* 1890. *Nitrate of Ammonia.* NH_4NO_3.—Ammonium nitrate may be prepared by treating commercial ammonium carbonate with nitric acid so long as effervescence takes place, or to saturation, filtering, and evaporating the solution. By careful evaporation and slow refrigeration the salt may be obtained in well-defined crystals. If crystallized after rapid concentration by boiling and sudden cooling, it forms long, flexible and elastic threads. If the solution be heated till all the water has been driven off and the fused mass kept at a temperature not exceeding 160° C. (320° F.), the commercial salt is produced. It is usually obtained as a by-product in the manufacture of other chemicals.

"Colorless crystals, generally in the form of long, thin, rhombic prisms, or in fused masses, without odor, having a sharp, bitter taste, and somewhat deliquescent. Soluble, at 15° C. (59° F.), in 0.5 part of water, and in 20 parts of alcohol; very soluble in boiling water, and in 3 parts of boiling alcohol. When gradually heated, it melts at 165°–166° C. (329°–330.8° F.); at a temperature between 230° and 250° C. (446°–482° F.) it is decomposed into nitrogen monoxide gas and water, leaving no residue. The aqueous solution of the salt is neutral to litmus paper, and when gently heated with potassium or sodium hydrate test-solution, it evolves the odor of ammonia. On heating the salt with sulphuric acid, it emits nitrous vapors." *U. S.*, 1890.

For further information concerning this salt, see *U. S. D.*, 19th ed., p. 1380.

For the mode of preparing nitrogen monoxide (hyponitrous oxide), or nitrous oxide gas, from ammonium nitrate, see *Nitrogen Monoxide*, p. 719.

Ammonium Persulphate, $(NH_4)_2S_2O_8$, is prepared by electrolyzing an acid solution of ammonium sulphate, and is a most efficient oxidizing agent in acid, neutral, or alkaline solutions. It occurs in small, colorless crystals, soluble in water. Its solution evolves oxygen when heated, and is used as an antiseptic and as a cheap and effective mouth wash. Ammonium persulphate is used in photography. In medicine it is chiefly valuable as forming the basis of *Klett's test* (*Chem. Ztg.*, 1900, p. 690) for indican in urine. To 10 mils (160 minims) of urine add 5 mils (80 minims) of 25 per cent. hydrochloric acid together with a crystal of ammonium persulphate, to which add chloroform, when a blue color develops in the latter.

Ammonium Phosphate. *N. F. IV, Br.*, 1898. *Ammonii Phosphas. Ammoniæ Phosphas. Phosphate of Ammonia. Phosphas Ammonicus. Phosphate d'Ammoniaque*, Fr. *Ammonium Phosphoricum. Phosphorsaures Ammoniak*, G. *Ammon. Phos.*—"It contains diammonium hydrogen phosphate [$(NH_4)_2HPO_4 = 132.13$] and ammonium dihydrogen phosphate [$NH_4H_2PO_4 = 115.09$], corresponding to not less than 20 per cent. of combined ammonia ($NH_3 = 17.03$). Preserve it in well-closed containers in a cool place." *N. F. IV.* "A salt, $(NH_4)_2HPO_4$, which may be obtained by neutralizing phosphoric acid with solution of ammonia." *Br.* (1898).

The *diammonium hydrogen phosphate* was formerly official, under the name of ammonium phosphate, in both the United States and British Pharmacopœias. The preparation recognized at present, by the N. F., is a mixture of this salt with the more acid ammonium di-hydrogen phosphate.

The process formerly given in the British Pharmacopœia involved treating diluted phosphoric acid with stronger ammonia water until the solution was slightly alkaline, then evaporating until crystals formed on cooling, ammonia being added from time to time in order to maintain constantly a slight excess of this base. Without such a precaution a portion of the more acid phosphate will be formed owing to the escape of the ammonia during the process of evaporation. This salt may also be made by saturating the excess of acid in acid calcium phosphate by means of ammonium carbonate. Calcium phosphate is precipitated and ammonium phosphate obtained in solution, which, being duly concentrated by a gentle heat, affords the salt in crystals upon cooling. The method of obtaining the acid calcium phosphate is given under the head of sodium phosphate. (See *Sodii Phosphas.*) Ammonium phosphate prepared in this way is a white salt, crystallizing in six-sided tables, derived from oblique quadrangular prisms, efflorescent, insoluble in alcohol, and soluble in four parts of cold water. The solution has an alkaline, somewhat saline taste, and an alkaline reaction, and gives off ammonia when heated.

The other acid phosphate, $NH_4H_2PO_4$, is obtained by boiling a solution of either of the other salts so long as ammonia escapes, and then crystallizing. Its crystals are four-sided prisms, permanent in the air, of an acid taste and reaction, and soluble in 5 parts of cold water. (Bridges.)

The ammonium phosphate of commerce is a mixture of these two phosphates and hence corresponds more closely with the N. F. definition.

The variety of phosphoric acid employed in this formula is the tribasic, which forms three salts with ammonia, one containing three atoms of ammonium without basic hydrogen, which is called the neutral phosphate, the second, two molecules of ammonium and one of basic hydrogen, forming an acid phosphate, and the third, one molecule of ammonium and two of basic hydrogen, forming also an acid phosphate. The second of these was

the one intended by the U. S. (1880) and British Pharmacopœias, and is represented by the formula $(NH_4)_2HPO_4$.

The description of this salt in the N. F. is as follows:

"Ammonium Phosphate occurs in colorless crystals, or as a white crystalline powder, losing ammonia on exposure to the air. One Gm. dissolves in about 4 mils of water; it is insoluble in alcohol. An aqueous solution (1 in 20) is neutral or alkaline to litmus. Separate portions of an aqueous solution of the salt (1 in 20) yield with magnesia mixture T.S. a white precipitate, with silver nitrate T.S., a yellow precipitate, and, upon warming with ammonium molybdate T.S., a yellow precipitate. Dissolve 1 Gm. of Ammonium Phosphate in 20 mils of distilled water; the resulting solution is not more than slightly turbid (*calcium, aluminum*). Ten mils of an aqueous solution of the salt (1 in 20), acidulated with nitric acid, is not rendered more than slightly opalescent by silver nitrate T.S. (*chloride*). Ten mils of an aqueous solution of Ammonium Phosphate (1 in 100) mixed with 2 mils of hydrochloric acid is not rendered turbid at once by the addition of a few drops of barium chloride T. S. (*sulphate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see *U. S. P.*, Test No. 3, Part III). An aqueous solution of the salt meets the requirements of the Test for arsenic (see *U. S. P.*, Test No. 1, Part III)." *N. F.*

Assay.—"Transfer about 1 Gm. of Ammonium Phosphate, accurately weighed, to a distilling flask, dissolve it in 300 mils of distilled water and add 25 mils of an aqueous solution of sodium hydroxide (1 in 4). Connect the flask with a small glass condenser, the lower outlet tube of which is inserted beneath the surface of 50 mils of half-normal sulphuric acid V.S., contained in a flask of about 500 mils capacity, and distil the liberated ammonia into the acid. Titrate the excess of acid with half-normal potassium hydroxide V.S., using methyl orange T.S. as an indicator, and calculate the percentage of ammonia in the salt. It shows not less than 20 per cent. of NH_3. Each mil of half-normal sulphuric acid V.S. used corresponds to 0.008515 Gm. of NH_3. Each gramme of Ammonium Phosphate corresponds to not less than 23.5 mils of half-normal sulphuric acid V.S." *N. F.*

The British Pharmacopœia (1898) gave the following quantitative test: "When 2 grammes are dissolved in *water*, and *solution of magnesium ammonio-sulphate* is added in excess, a crystalline precipitate should be formed, which, after being well washed upon a filter with *solution of ammonia* diluted with an equal volume of *water*, and then dried and heated to redness, weighs 1.68 grammes." The amount of the residue, which is magnesium pyrophosphate, indicates the quantity of phosphoric acid contained in the salt. This quantitative test for phosphoric acid was for the purpose of identifying the di-ammonium hydrogen phosphate.

This salt was first brought to the notice of the profession as a remedy for *gout* and *rheumatism*, by T. H. Buckler (*A. J. M. S.*, 1846), and has since been so employed with apparently useful results.

Dose, from five to thirty grains (0.32–1.9 Gm.), three or four times a day, dissolved in a tablespoonful of water.

Ammonium Sulphate. *Ammonii Sulphas. U. S.* 1880. *Sulphate of Ammonium.* $(NH_4)_2SO_4$; 131.21. *Ammonium Sulphuricum. Sal Ammonium Secretum Glauberi. Sulfate d'Ammoniaque, Sel secret de Glauber*, Fr. *Schwefelsaures Ammon, Ammonium, Ammoniak*, G.—Gas liquor is distilled with lime and the gas received in sulphuric acid, which yields a purified product. Most of the ammoniacal liquor is worked up into ammonium sulphate at present. In the United States the production of ammonium sulphate has increased enormously in recent years, owing to the introduction of by-product coke ovens. In 1915 the production from this source was 197,000 tons, of which 50,700 tons additional were obtained from coal gas plants. The total value was $11,175,000. (*U. S. Geological Survey Report*). "Colorless, transparent, rhombic prisms, permanent in the air, odorless, having a sharp, saline taste and a neutral reaction. Soluble in 1.3 parts of water at 15° C. (59° F.) and in 1 part of boiling water; insoluble in absolute alcohol, but slightly soluble in alcohol of sp. gr. 0.817; when heated to about 140° C. (284° F.), the salt fuses, is gradually decomposed, and on ignition is wholly dissipated. The aqueous solution of the salt, when heated with potassa, evolves vapor of ammonia. With test-solution of chloride of barium it yields a white precipitate insoluble in hydrochloric acid. A 1 per cent. solution of the salt should not be blackened by test-solution of sulphide of ammonium (lead and iron), nor, when acidulated with nitric acid, should it be rendered more than opalescent by test-solution of nitrate of silver (limit of chloride)." *U. S.*, 1880. It is not used as a medicine, but enters into the composition of ammonium alum and the iron and ammonium sulphate, and is the principal source of ammonia gas used in chemical manufacturing, refrigeration, etc.

Ammonium Tartrate.—The neutral ammonium tartrate has been used by Clausen for the clearing up of *corneal opacities*. The eye is irrigated with a warm neutralized solution containing 5 per cent. of ammonium tartrate for twenty to thirty minutes two or three times a day.

Ammonium Uranate. *Ammonii Uranas.* $NH_4 U_2O_7 + (H_2O)_n + Aq$.—This is a reddish-yellow, amorphous powder, insoluble in the usual solvents. It has been used by Weil (*S. M.*, 1907, p. 573) with asserted favorable results in the treatment of *syphilis*. The remedy was administered in doses of five-sixth grain (0.05 Gm.), suspended in a liquid petrolatum, by intra-muscular injection. The strength of the suspension was 5 per cent. and the injections were made once a week. The treatment required on an average of two months. It is used in the arts for painting on porcelain.

Ammonium Urate. *Ammonii Uras.* $C_5H_3(NH_4)N_4O_3$.—This is an acid salt, and may be formed by digesting uric acid in solution of ammonia, or by adding sal ammoniac to the solution of other urates. Uric acid is frequently obtained from the dried and powdered excrements of the boa constrictor, and of other large snakes, by dissolving it in a weak solution of potassium hydroxide with the aid of heat, and precipitating the uric acid from the filtered solution by hydrochloric acid, added in excess. Ammonium urate is a white, amorphous, very sparingly soluble salt. It is a constituent of some varieties of guano. It has been used with asserted good effects externally in chronic *eczema*, in the form of an ointment (twenty grains to the ounce). (See 16th edition

U. S. D.) Neubauer found that when given internally to rabbits it causes increase in the urea, uric acid, and oxalates of the urine. (*Ranking's Abstract*, 1857.)

Amygdophenin. *Phenetidin Amygdalate.* $C_6H_4.OC_2H_5NH.CO.CH.OH.C_6H_5$. *Phenyl-glycol-phenetidin.*—This is a derivative of *p-amidophenol*, analogous to phenacetin. In constitution it is a light, crystalline, grayish-white powder, soluble with difficulty in water. It is obtained by the action of mandelic acid upon *p-phenetidin* in the presence of dehydrating agents. R. Stüve asserts that it is practically free from antipyretic properties; that it is an analgesic which is often useful in *neuralgias* and the pains of *spinal scleroses;* and that it is very useful in *rheumatism*, it having had more effect in some comparative trials than the salicylates. It is best administered in capsules, fifteen grains (1 Gm.), from three to six times a day.

Amyl Alcohol. *Alcohol Amylicum. Amylic Alcohol*, $C_5H_{11}OH$. *Hydrated Oxide of Amyl. Fousel Oil. Fusel Oil. Hydrate of Amyl. Grain Oil. Potato Spirit Oil. Alcool Amylique, Huile de Grain*, Fr. *Amylalcohol, Fuselöl*, G.—This alcohol is always present in the products of alcoholic fermentation, and, according to the experiments of L. Perdrix (*J. Chem. S.*, 1892, 90), the bacillus *B. amylozymicus* produces a fermentation in starch resulting in a large production of amyl alcohol. It is an ingredient in the ardent spirit obtained from various grains, but is most abundant in that procured from fermented potatoes. In grain spirit it is present in the proportion of about one part in five hundred by measure. When grain or potato whisky is distilled for the purpose of obtaining alcohol, the pure spirit will continue to come over for a certain time, after which, if the distillation be continued, a milky liquid will be obtained, which, upon standing, will be covered with a stratum of amyl alcohol. Subjected to distillation, the milky liquid will at first boil at a comparatively low temperature, and yield water and a little of the alcohol; but after a time the boiling point will rise to 132° C. (269.6° F.), when the amyl alcohol will come over pure, and by changing the receiver may be so collected.

Properties.—Amyl alcohol is an oily, colorless liquid, of a strong, characteristic odor, and an acrid, burning taste. As usually prepared it has a pale yellow color. Its sp. gr. is 0.818; that of its vapor 3.15. It boils at 132° C. (269.6° F.), and congeals at −25° C. (−13° F.) in the form of crystalline leaves. It is very sparingly soluble in water, but unites in all proportions with alcohol, ether, and essential oils. It dissolves iodine, sulphur, and phosphorus, and is a good solvent for fats, resins, camphor, and alkaloids. When dropped upon paper it does not leave a permanent greasy stain. It does not take fire like alcohol by the contact of flame, but requires to be heated to a temperature of about 54.5° C. (130° F.) before it begins to burn. Pasteur first observed that the ordinary amyl alcohol of fermentation was a mixture of two distinct alcohols, one present in smaller amount, optically active, levogyrate, and the other, the main portion, optically inactive. Their boiling points are very close, but they may be separated by the difference in solubility of the barium amyl-sulphates, and yield different sets of derivatives. (*C. R. A. S.*, 41, 296.) Heated with phosphoric acid, it loses a molecule of water, and forms a hydrocarbon, C_5H_{10}, homologous with ethylene, called *amylene* or *valerene*, which has been proposed as an anesthetic. According to Long and Linebarger, American fusel oil consists chiefly of active and inactive amyl alcohol, with some isobutyl alcohol, isopropyl and ethyl alcohols, and traces of normal propyl and normal butyl alcohols. (*Chem. News*, lxi, 185–187.) Amyl alcohol should not affect the color of litmus paper, previously moistened with water, should leave no fixed residue upon evaporation, should require to dissolve it about 40 parts of distilled water at 15° C. (59° F.), and should become not more than slightly turbid upon mixture with petroleum benzin (absence of more than a little alcohol, or water). (See *Amylene* below.) When subjected to oxidizing agents, it loses two atoms of hydrogen and gains one of oxygen, and becomes $C_5H_{10}O_2$, or *valeric acid*, the acid found in valerian. Hence the test given in the Br. Pharmacopœia of 1885: "Exposed to the air in contact with platinum-black, it is slowly oxidized, yielding valerianic (valeric) acid." This acid bears the same relation to amyl alcohol that acetic acid does to ethyl alcohol, and formic acid to methyl alcohol. The free amyl, $(C_5H_{11})_2$, has been isolated by E. Frankland. It is a colorless, transparent liquid, of the sp. gr. 0.7704. (*Chem. Gaz.*, March 15, 1850.) Its hydride, $C_5H_{11}H$, was discovered to be an energetic anesthetic by Simpson of Edinburgh. A mixture of amyl alcohol, green soap, phenol (1 per cent.) and water, under the trade name of *Amyl Karbol*, has a wide use in Europe as a disinfecting solution.

Crude fusel oil may be obtained from the alcohol distillers. Kent, of New York, found in it, as impurities, water, alcohol, acetic and valeric acids, oxide of iron, and an amyl compound analogous to *œnanthic ether*. Fusel oil has been used largely by the manufacturers of alkaloids as a solvent and in the preparation of *amyl acetate* (*pear oil, banana oil*), which is used in the manufacture of pyroxylin varnishes and smokeless powder and as a basis for the manufacture of isoprene, lately used in the manufacture of synthetic cacoutchouc. This manufacture of amyl acetate for solvent purposes now consumes the great bulk of the fusel oil obtained from the rectifiers.

Fusel oil was formerly recognized by both the United States and the British Pharmacopœias as an artificial source of valeric acid.

Amyl alcohol is a very active narcotic, and under the name of *Faints* (*feints*) is used in England and Northern Europe for the purpose of increasing the activity and prolonging the effects of ordinary liquors. In small doses it is said to be especially efficacious in controlling the nervous weakness and irritability of confirmed drunkards, while larger doses produce headache, giddiness, double vision, staggering, unconsciousness, fall of temperature, abolition of reflexes, muscular rigidity, followed by complete relaxation, pronounced cyanosis, and a peculiar odor from the breath suggesting that of a Jargonelle pear.

Horand has employed amyl alcohol for its disinfecting and dessicating action in inoperable *cancerous ulcers*. (*R. T.*, 1910.) He asserts that by the local application of from three to ten drops daily there is not only a disappearance of the odors, but often a shrinking in the size of the tumor, and considerable improvement in the general condition.

T. B. Futcher (*Am. Med.*, August, 1901, p. 210) has shown that both in animals and also in man, when taken in toxic doses, fusel oil affects profoundly the blood, causing methemoglobinuria,

also glycosuria, attended with the presence of combined glycuronic acid, and in some cases violent nephritis. The size of the fatal dose probably varies very much. It is affirmed that death occurred from the taking of a single fluidounce (30 mils), but in another case recovery resulted after six fluidounces (180 mils) had been swallowed.

Amyl Salicylate. *Salicylic Amylester. Amylenol.*

A colorless to a yellow refracting fluid, possessing an odor resembling that of salol, having the sp. gr. 1.065 at 15° C. (59° F.) and made by the action of chlorine on a solution of salicylic acid in amyl alcohol. It boils at 270° C. (518° F.). It is slightly dextrorotatory. Refractive index (20°) 1.505–1.507. The preparation dissolves in ether, alcohol, and chloroform, but it is almost insoluble in water. This substance has been proposed by B. Lyonnet (*R. T.*, lxviii, No. 2) as a substitute in *rheumatism* for methyl salicylate, over which it has the advantage of less pronounced odor and taste. It is also coming into wide use as a fixing agent for delicate odors in the perfumer's art. It is given internally usually in gelatin capsules, three to five minims (0.2–0.3 mils) each, eight or ten times a day. It has also been found very useful as a local application, one-half to one drachm (2.0–3.9 Gm.), being applied to rheumatic joints and covered with wax paper, or other impervious dressing. It is incompatible with acids or acid salts and with iron compounds.

Amyl Valerate. *N. N. R.* 1917. $C_4H_9COOC_5H_4$.—The isovaleric acid ester of iso-amyl alcohol. A colorless liquid having, when diluted with alcohol, in which it is very soluble, an odor of apples. Insoluble in water, sp. gr. 0.858; boiling point 188°–190° C. (370.4°–374° F.). It has been used in the place of valerian in the treatment of various nervous conditions.

Pouchet asserts that amyl valerate (*J. des Pr.*, 1899, 45) has the power of softening, or if present in sufficient quantity, of dissolving cholesterin, and recommends its use in the treatment of *gall-stones*. *Dose*, three to eight minims (0.2–0.5 mil). Technically it has been used as an artificial apple flavor.

Amylamine Hydrochloride, *Amylamine Chloride*, $C_5H_{11}NH_2HCl$, $C_5H_{13}N.HCl$, crystallizes either in efflorescent scales or in quadratic octahedrons. According to Dujardin-Beaumetz (*C. R. A. S.*, lxxvii, 1247), in small doses (from $^1/_{60}$–$^1/_{12}$ grain (0.001–0.005 Gm.) to a rabbit) this salt lowers the temperature and also the force and frequency of the pulse. In larger amounts it produces profound nervous disturbance, with tonic and clonic convulsions, ending often in death. In man, doses of from seven to fifteen grains (0.45–1.0 Gm.) diminish the pulse and temperature.

From amylamine hydrochloride by boiling with an excess of calcium chloride is formed *amyldichloramine*, a yellowish-green oily liquid, the smelling of which produces violent irritation of the mucous membrane of the nose, followed by severe headache and vertigo. According to the researches of Boinet (*Congrès Français de Méd.*, 1, 1894), it is not only a violent local irritant, but also a powerful centric poison, producing death by asphyxia. Boinet has also examined physiologically *propyldichloramine* and *isobutyldichloramine*, finding that they are similar in their toxic influence to amyldichloramine.

Amylene. *Valerene. Pentene.* C_5H_{10}.—This compound was alluded to under amyl alcohol. The name is given to the isomeric hydrocarbons of the olefin series, having the formula C_5H_{10}, of which five are possible. Amylene is prepared by distilling amyl alcohol with a concentrated solution of zinc chloride, which acts by dehydrating, withdrawing a molecule of water. The product is redistilled, and that which comes over first, constituting the more volatile part, is separately collected, and agitated with concentrated sulphuric acid, when the amylene, freed from water, will rise to the surface. Amylene is a colorless, very mobile liquid, having the density 0.655 at 10° C. (50° F.). Its boiling point is 34° C. (93.2° F.). Its odor is peculiar and disagreeable. It is soluble in alcohol and ether in all proportions, but very sparingly so in water. When pure it does not act on potassium, and is not colored by a prolonged contact with potassium hydroxide.

In 1857, Snow, of London, proposed amylene as an anesthetic. It was soon shown, however, to be dangerous, the French Academy of Medicine formally condemning it.

Amylene Hydroxide. Amylene Hydrate. Tertiary Amyl Alcohol. Dimethylethylcarbinol ($C_5H_{12}O$ or $(CH_3)_2C.(C_2H_5)OH$) is a clear, colorless liquid, of a strong, penetrating odor, soluble in eight parts of water, and miscible with alcohol, ether, chloroform, petroleum benzin, glycerin, and fixed oils in almost all proportions; sp. gr. 0.812 at 12° C. (53.6° F.).

In 1887, von Mering proposed the use of amylene hydroxide as a soporific, stating that it stood midway between hydrated chloral and paraldehyde, one drachm (3.9 Gm.) of hydrated chloral, two drachms (7.7 Gm.) of amylene hydroxide, and three drachms (11.6 Gm.) of paraldehyde being about equivalent in power. In cases of poisoning, reported by C. Dietz, by the amylene hydroxide, the symptoms were deep narcosis, dilated pupils, loss of corneal reflexes, slow, deep, irregular breathing, small, slow pulse, and fall of temperature. Amylene hydroxide is a safe, rapidly acting, and occasionally useful but not analgesic hypnotic, in doses of from thirty to forty minims (1.8–2.5 mils). According to Brackmann, confirmed by W. Niessen, it is very valuable in *diabetes insipidus*, lessening thirst and polyuria. Amylene hydrate has also been recommended for the relief of *epileptic* and *eclamptic convulsions*. *Dose*, fifteen minims (0.9 mil) morning and evening.

Pental. Trimethylethylene. β-isoamylene, $(CH_3)_2C=CH.CH_3$, or C_5H_{10}, is obtained from crude amylene, which consists of pentane (C_5H_{12}), pental (C_5H_{10}), and α- and γ-amylene. If the mixture be shaken with diluted sulphuric acid at a low temperature, −20° C. (−4° F.), the trimethylethylene and γ-amylene will be decomposed and amylsulphuric acid produced, which after dilution with water yields tertiary amyl alcohol and trimethylethylene; by fractional distillation the pental is obtained in a pure state.

Pental is a colorless, highly inflammable liquid; sp. gr. 0.678; boiling point 38° C. (100° F.). It was highly commended by W. Lombardino as an anesthetic of great practical value. H. C. Wood and David Cerna have, however, shown that pental acts upon the lower animals as a powerful cardiac depressant, and clinical experience has demonstrated that it is too dangerous for practical use.

Pentane.—Amyl hydride, $CH_3CH_2CH_2CH_2CH_3$, was discovered by E. Frankland of Manchester. It is a saturated hydrocarbon, and has been proved to be one of the light products in American petroleum, being the portion boiling at from 37°–39° C. (99°–102° F.) (Schorlemmer). Amyl hydride is a colorless, volatile, mobile liquid, possessing a fruity odor, and having no taste. It is one of the lightest liquids known, having the sp. gr. 0.626 at 17° C. (63° F.). It boils at 38° C. (100° F.), and the sp. gr. of its vapor is 2.5. It is very inflammable, and burns with a brilliant white flame. It is readily soluble in alcohol and ether, but insoluble in water. Belonging to the paraffin or saturated series of hydrocarbons, it is a very stable compound, resisting the action of fuming sulphuric acid and the most powerful oxidizing agents. This substance was proposed by Simpson as an anesthetic, but has not sustained the claims made for it. It is used as a solvent in analytical chemistry and as an illuminant in photometric determinations.

Amylene Carbamate.—Under the name *aponal* amylene carbamate $NH_2—CO—O—C(CH_3)(C_2H_5)—CH_3$ has been introduced as a somnifacient. It seems to be a drug of only moderate power but acting promptly and apparently without injurious after-effects. The *dose* is from eight to thirty grains (0.5–2 Gm.).

Amylene Chloral. *N. N. R.* 1916. *Dormiol. Methyl Butanol Chloral* (in 50 per cent. solution).

$$CCl_3.CH(OH)(OC_5H_{11})$$

—This is a compound formed by the union of chloral and amylene hydroxide. It is a colorless, oily fluid of sp. gr. 1.24, having a peculiar camphor-like odor and a cooling, pungent taste. It is insoluble in water but is miscible in all proportions with alcohol, ether, acetone, and fixed oils. Its incompatibilities are the same as those of chloral. There is a large amount of clinical evidence as to the value of dormiol in all forms of *insomnia* which are not dependent upon the existence of pain. It is employed largely in insane asylums, and the testimony is uniform that it acts favorably in about 70 per cent. of the cases, that it produces no disagreeable after-effects, and that when continuously exhibited it produces no chronic poisoning. It is further claimed that it may be used in cardiac cases when hydrated chloral would be dangerous. It acts promptly and produces a quiet sleep, which is often of very short duration; further, patients become rapidly accustomed to its use. *Dose,* ten to forty-five minims (0.6–2.9 mils). It may be given in capsules or emulsion, but it is well taken when dropped in cold water and quickly swallowed.

Amyloform is a patented chemical compound of formaldehyde and starch, introduced by Claassen as a substitute for iodoform. It is stated to be odorless, innocuous, and non-irritant. *Dextroform* is a similar compound, in which dextrin is used in place of starch. Dextroform is soluble in water and glycerin. Amyloform can be heated to 180° C. (356° F.) without decomposition, and therefore is readily sterilized. It is said to be non-poisonous, and has been used by Langgard, Krabbel, and others as a dusting powder in the treatment of infected *ulcers* and wounds of all kinds. It is said to act more energetically in lessening secretion and as a disinfectant than iodoform.

Amytin.—The ammonium salt of a mixture of sulphonated hydrocarbons prepared by the action of sulphuric acid on various hydrocarbons and subsequent treatment with ammonia. Under the name of amytin (*anytin, anysin*), Unna has introduced into medicine a 33 per cent. aqueous solution of *ichthyol-sulphonic acid,* which has the property of dissolving ichthyol, various ethereal oils, phenol, and camphor, forming solutions which are known by Unna as *Amytoles* (*anytoles*). Amytin is more or less irritant to the skin, and is affirmed to be useful in those skin diseases which need stimulation.

Anacahuite Wood.—In the year 1860 considerable quantities of this wood were imported from Mexico, into Germany, as a supposed remedy in *phthisis,* but it failed to sustain its first reputation. It is the product of *Cordia Boissieri* DC. (See *P. J.*, Dec., 1862, 272, with figure.)

Anacardium. *Anacardium occidentale* L. *West Indian Cashew-nut. Acajou à Pommes,* Fr. *Caschunuss,* G.—A small and elegant tree of the Fam. *Anacardiaceæ,* growing in the West Indies and other parts of tropical America. A gum exudes from the bark, which bears some resemblance to gum arabic, but is only in part soluble in water, and consists of true gum and bassorin. It is the *gomme d'acajou* of the French writers. Peckoldt describes *cashew gum* as occurring in hard, fragile pieces which are more or less transparent, yellowish-brown, and stalactite-shaped, and is as soluble in water as acacia. (*Zeit. Oest. Apoth. Ver.,* 1893, 501.) The fruit is a fleshy, pear-shaped receptacle, supporting at its summit a hard, shining, ash-colored, kidney-shaped nut, an inch or more in length and three-quarters of an inch broad, consisting of a pericarp having large balsam canals and of a sweet oily kernel which is now an article of commerce, as a food sold either in the raw state or roasted and salted. The receptacle is red or yellow, and of agreeable subacid flavor with some astringency. It is edible, and affords a juice which has been recommended in *uterine complaints* and *dropsy.* This juice is converted by fermentation into a vinous liquor, which yields by distillation a spirit used in making punch, and said to be powerfully diuretic. The black juice contained between their outer and inner shell of the nuts is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or desquamation. Staedeler found in it two peculiar principles—*anacardic acid* and a yellow, oleaginous liquid, *cardol.* (See *J. P. C.,* 3e sér., xiii, 459.) The juice is used in the West Indies for the cure of *corns, warts, ringworms,* and obstinate *ulcers,* and even of *elephantiasis.* It is said to be sometimes applied to the face by women, in order to remove the cuticle, and produce a fresher and more youthful aspect. In a case of external poisoning which came under observation, in a lady who was exposed to the fumes of the roasting nuts, the face was so much swollen that for some time not a feature was discernible. (*N. J. Med. Rep.,* 1855, 187.) In the case of a boy the tongue, face, neck, hands, forearms, scrotum, etc., were red and enormously swollen, and very painful. The tincture of iodine was found useful as a local application. The black juice of the nut and a milky juice which flows from the tree after incision are used for almost indelibly marking linen. The *Oriental*

Cashew-nut or *Anacardium Orientale* is the fruit of *Semecarpus Anacardium*, L., a tree quite common in Southern Asia. It contains principles similar to the West Indian Cashew, and is also said to contain an alkaloid, *chuchunine*.

Anagallis. *Anagallis arvensis*, L. *Scarlet Pimpernel. Red Chickweed. Weather-glass. Mouron rouge*, Fr. *Gauchheil, Rothe Miere*, G. (Fam. *Primulaceæ.*)—An annual plant, growing in Europe and the United States. It has little odor, but a bitterish, somewhat acrid taste. The ancients esteemed it a counter-poison, and Orfila found three drachms of its extract to cause fatal gastro-enteritis in a dog. It has been recommended as a local application to old and ill-conditional *ulcers*, and has been used as a folk-remedy in *visceral obstructions, consumption, dropsy*, etc. J. A. Heintzelman obtained from it a volatile oil of a strong, peculiar odor, a pungent and somewhat acrid taste, and the sp. gr. 0.987. Four drops (0.25 mil) of it produced intense headache and nausea, lasting for twenty-four hours, with pains throughout the body. According to Daccomo and Tommasoli, anagallis contains an active ferment, which rapidly digests raw meat. (*Rassegna di Sci. Med.*, 1892, No. 4.) *A. cœrulea* (Schreb.) Ledeb., having blue petals, is a variety of *A. arvensis*, and shares its medicinal properties.

Anagyris. *Anagyris fœtida*, L. (Fam. *Leguminosæ.*)—Hardy and Gallois have separated from *Anagyris fœtida* an alkaloid, *anagyrine*. Parthiel and Spasski found that the crude alkaloid could be separated into *cytisine*, $C_{11}H_{14}N_2O$ and *anagyrine*, $C_{15}H_{22}N_2O$; the latter is not obtainable in crystalline form; it forms a brittle, resinous-like mass easily reducible to a yellowish powder, but rapidly absorbs moisture and becomes sticky. It volatilizes at 245° C. (473° F.). (*Arch. d. Pharm.*, 244, No. 1, 1906, 20.) It forms, however, a crystalline hydrobromide.

Anagyrine hydrobromide, which has the formula $C_{14}H_{18}N_2O_2HBr$, occurs in colorless or faintly yellow crystals and soluble in water. Anagyrine, according to Loewi (*A. I. P.*, vol. vii, p. 66), is physiologically related to lobeline, acting primarily upon the nerve endings as a paralyzant and later upon nerve centers, but having no direct influence upon the muscles. It lessens the cardiac frequency and decreases the force of the systole in the frog, but is said in the mammal to have very little influence upon the blood pressure, death occurring through respiratory paralysis.

Analgen. *Ortho-ethoxy-monobenzoyl-amido-quinoline. Benzanalgene. Quinalgene. Labordin.* $C_{18}H_{16}N_2O_2$. $C_9H_5.(OC_2H_5)NH(CO.C_6H_5)N$.—The name analgen was first given to the acetyl derivative, but it was found that the benzoyl radical gave a more desirable product, and this is now made exclusively and the name analgen applied to it. It is in colorless crystals, insoluble in water, soluble in hot alcohol, melting point 208° C. (406° F.).

First produced and brought forward by Vis as an antipyretic, analgesic, and antirheumatic remedy, it was subsequently investigated by Maass (*Z. K. M.*, xxviii, 1895), who found that in sufficient dose it depresses the heart and the reflexes, finally causing convulsions with loss of power, and death by centric paralysis of respiration. Both it and its derivative, *oxyethylamidoquinoline*, act upon the peripheral nerves as local anesthetics. The fatal dose for the lower animals was found by Maass to be three grammes per kilo. The continuous use of small doses produces emaciation, feebleness, and lessening of the reflexes. In cases of fever it causes active depression of temperature, often with free sweating, and usually decrease in the urinary secretion, and especially of the nitrogenous elimination. After chronic poisoning in the lower animals fatty degeneration was found in the liver and kidneys. The urine of patients taking it is said to become red, owing to the presence of *oxyethylamidoquinoline urate*. In *headaches* and the other nervous disturbances of *neurasthenic* individuals it is said to act well without affecting digestion. It is said also to relieve the pain of organic diseases, and to be distinctly anti-malarial. (See *B. A. M.*, xxxvi.) *Dose*, eight to fifteen grains (0.5–1.0 Gm.), up to forty-five grains (0.3 Gm.) a day if required; best administered in capsule or in acidulated water.

Anchietea. *Anchietea salutaris* St. Hil. *Cipo Suma. Cipo Carneiro. Pirageia.* (Fam. *Violaceæ.*)—The bark of the root of this Brazilian plant contains *anchietine*, an alkaloid isolated by Peckoldt. (*Ber. d. Chem. Ges.*, 1897, p. 98.) It is used in Brazil in treating *scrofula, erysipelas*, and *eczema*. Given in *doses* of two drachms (7.7 Gm.), it acts as an aperient, while three drachm (11.6 Gm.) doses produce vomiting.

Anchusa. *Anchusa officinalis*, L. *Bugloss. Ox-tongue.* (Fam. *Boraginaceæ.*)—The root, leaves, and flowers of this European biennial plant were at one time recognized by the U. S. Pharmacopœia, but probably are practically devoid of medicinal properties. In France the *Anchusa italica*, which is there known as *buglosse*, is substituted for *A. officinalis* and is still in popular use as a diaphoretic and diuretic.

Andrographis. *Br. Add.* 1900. *Andrographis paniculata* Nees. (Fam. *Acanthaceæ.*)—Under the name of *Kiryat* this plant is stated to be used to some extent in India as a bitter tonic, having similar properties to chiretta. It appears scarcely to enter commerce at all, although exposed in the shops of the herbalists. (See *B. P. C.*, p. 122.) The Br. Add., 1900, recognized the *infusion* (*Infusum Andrographidis*, one ounce to a pint), *dose*, one-half to one fluidounce (15–30 mils); the *concentrated liquor* (*Liquor Andrographidis Concentratus*), *dose*, one-half to one fluidrachm (1.8–3.75 mils); and the *tincture* (*Tinctura Andrographidis*), *dose*, one-half to one fluidrachm (1.8–3.75 mils).

Andromeda. *Oxydendrum arboreum* (L.) DC., (*Andromeda arboreum* L.), *Sour Wood*, or *Sorrel-tree*, grows in the valleys of the Alleghanies, from Pennsylvania to Florida and west from Indiana to Louisiana. The decoction of the leaves was at one time used as a pleasantly acidulous drink in fevers. The powder of the leaves and buds of *Leucothoë racemosa* (L.) A. Gray (*Andromeda racemosa* L.) is said to be a powerful errhine.

J. F. Eykman, of Japan, found a poisonous glucoside, *asebotoxin*, in *Andromeda* (*Pieris*) *japonica*. (*N. R.*, 1882, 290.) In 1883, Plügge separated from *Andromeda japonica* a colorless, crystallizable, poisonous principle, *andrometoxin*. Subsequently he found that various ericaceous plants contain it. (*A. Pharm.*, xxvi; also *A. J. P.*, 1889.) It exists in *Azalea indica* and *Rhododendron maximum* L., and has been found by De Zaayer (*Chem. Ztg.*, July, 1887) in *Rhododendron ponticum*, and in *Kalmia angustifolia* L., and *K. latifolia* L.; also in *Monotropa uniflora* L., by A. J. M. Lasché (*Ph. Rund.*, Sept., 1889). It occurs in acicular crystals, melting at from 228° to 229° C. (442°–

444° F.), soluble in alcohol, amyl alcohol, chloroform, ether, benzene, much more soluble in cold than in boiling water, yielding solutions of an alkaline reaction, but not precipitated by ordinary alkaloidal reagents nor by solutions of metallic salts. For further tests, see reference; also *P. J.*, vol. xviii, 171. The *poisonous honey* of Xenophon, derived from the flowers of *Rhododendron ponticum*, probably owed its toxic properties to andrometoxin. (See also *Ph. Z. R.*, 1883, xxii.) The oil of *Andromeda Leschenaultii*, of India, was found by J. Broughton to be methyl salicylate. (*P. J.*, Oct., 1871.)

Anemonin. (*Pulsatilla Camphor.*) $C_{10}H_8O_4$. —Yellowish-white crystals soluble in hot alcohol and insoluble in water. It is used as an antispasmodic, sedative and anodyne in *asthma* and pulmonary affections. *Dose*, one-fourth to three-fourth grain (0.015–0.05 Gm.), although as high as three grains (0.2 Gm.) has been administered.

Anesthesin. *N. N. R.* 1917. *Ethyl-ester of p-amido-benzoic acid. Ethyl aminobenzoate.* $COOC_2H_5[1].C_6H_4.NH_2[4]$.—This is a white, inodorous, crystalline powder, melting at 89.5° C. (193° F.), sparingly soluble in cold water, readily soluble in acetone, ether, petroleum benzin, chloroform, and in ethereal and fatty oils. The solutions do not alter even when exposed to light. Its oily solution may be boiled without decomposition, but prolonged boiling with water causes a breaking up of the compound. It is incompatible with acids and acid salts.

Anesthesin hydrochloride is soluble in 100 parts of water. This solution when injected, however, causes some unpleasant burning sensation and may be diluted to one-fourth. It is claimed for anesthesin that while not poisonous it is an active local anesthetic and may be freely injected in solution for surgical purposes. In the experiments of Binz colossal doses given to rabbits were found to produce only a transient methemoglobinemia. No renal irritation or methemoglobinuria were ever observed. Dunbar commends the following formula: Anesthesin hydrochloride, 0.25; sodium chloride, 0.15; morphine hydrochloride, 0.005 to 0.015; water, 100; the solution can be sterilized. As a local application in ulcerated conditions of the nose and throat, as *tuberculous laryngitis*, it may be applied in the form of insufflation or by lozenges (one-third to two-thirds grain, 0.02–0.04 Gm.). It is also externally useful to insensitize the surfaces of *wounds* and *ulcers*, as *burns*, etc. In the form of an ointment it may be used for *hemorrhoids*, *pruritus vulvæ*. Externally it may be used in the form of powder or ointment in 5 to 20 per cent. strengths. See also Merck's *Ann. Report*, 1913. Reiss (*Ther. Geg.*, 1905) highly recommends anesthesin for the relief of *vomiting* when due to gastric irritation. He has found that it counteracts the emetic properties of antimony, but not those of apomorphine, which goes to show that its antemetic action is not central. It is also useful in the same way to relieve the pains of *gastric ulcer*. Ordinarily the *dose* in these conditions is eight grains (0.5 Gm.), although, according to Reiss, if necessary it may safely be increased to as high as one hundred and twenty grains (8 Gm.). He finds it of no service in seasickness. Lozenges containing from three-tenths to six-tenths of a grain (0.019–0.038 Gm.) are stated to be effective in relieving irritation of the throat and palate. Anesthesin has been found very useful, in the form of suppositories containing from three to eight grains (0.2–0.5 Gm.), for the relief of painful *hemorrhoids;* it is also used in soluble bougies in the *vesical tenesmus* of women; in the form of an ointment (10 per cent.) in *pruritus vulvæ*, also in various *eczemas* about the genitalia. *Dose*, five to seven grains (0.3–0.45 Gm.).

Anesthol. *Anesthyle.*—This has a wide use abroad as a local anesthetic in dental surgery, and is composed of a solution of methyl chloride in ethyl chloride in unknown proportions. The same name * is also given to a general anesthetic combination of ether, chloroform and ethyl chloride.

Angelica.—Two species of this genus are used in medicine, the *Angelica Archangelica* L. (*Garden Angelica*), a native of Europe, and the *A. atropurpurea* (*Masterwort*), which grows throughout the eastern United States. *Garden angelica* has a long, thick, fleshy, biennial root, furnished with many rootlets, and sending up annually a hollow, jointed, round, channelled, smooth purplish stem, which rises five feet or more in height, and divides into numerous branches. The plant is a native of the north of Europe, and is found in the high mountainous regions in the southern section of that continent, as in Switzerland and among the Pyrenees. It is often cultivated. The whole plant is aromatic, but the root only is official in the Swiss, Austrian, and German Pharmacopœias, while the fruit is official in the N. F. IV. The root should be dug up in the autumn of the first year, as it is then least liable to become mouldy and worm eaten. It is spindle-shaped, 4 to 6 cm. thick at the crown, and beset with long descending rootlets. The fresh root has a yellowish-gray epidermis, a fleshy yellow parenchyma, and when wounded yields a honey-colored juice, having all the aromatic properties of the plant. The dried root is grayish-brown and much wrinkled externally, whitish and spongy within, and breaks with a starchy fracture, exhibiting shining resinous masses. It is very apt to be attacked by insects. The drug and the powder should be conserved by the addition of a few drops of chloroform or carbon tetrachloride. The odor is strong and fragrant, and the taste at first sweetish, afterwards warm, aromatic, bitterish, and somewhat musky. These properties are extracted by alcohol, and less perfectly by water. The constituents of the root are *angelic acid*, $C_5H_8O_2$, a monatomic acid of the acrylic series, valeric acid, $C_5H_{10}O_2$, resin, bitter principle, tannin, pectin, malic acid, sugar starch and a volatile oil consisting largely of phellandrene. For further information concerning the constituents of this drug, see *U. S. D.*, 19th ed., p. 1386. *Schim. Rep.*, 1902, 15; 1911, 21; 1913, 26.

Angelicæ Fructus, N. F. IV, *Angelica Seed*, is described by the N. F. as "the ripe fruit of *Angelica Archangelica* Linné (Fam. *Umbelliferæ*) and of other species of *Angelica*, without the presence of more than 3 per cent. of foreign matter. Cremocarps oval, externally of a pale yellowish-brown color, from 4 to 8 mm. in length, 3 to 6 mm. in breadth and from 1 to 2 mm. in thickness, the base faintly notched, the summit bearing five minute calyx-teeth and the remains of the style; the two mericarps joined by their broad faces, or separate; each mericarp nearly flat upon one surface, which bears a central longitudinal groove and has sharp, slightly upturned margins, convex upon the other surface which is traversed longitudi-

* Sometimes spelled *Anæsthol.*

nally upon the back by three strong ribs, separated from one another by narrow grooves and from the margin by much broader grooves; pericarp soft, rather tough and corky, and enclosing a single seed, showing on cross section six large oil-tubes. Odor characteristic and agreeable; taste aromatic, pungent, and sweetish. Angelica Fruit yields not more than 8 per cent. of ash."

Garden angelica is an aromatic tonic. The Laplanders, in whose country it flourishes, esteem it highly as a condiment and medicine. In Europe the stems are frequently made into a preserve. The *dose* of the root or seeds is from thirty grains to a drachm (2–3.9 Gm.).

The N. F. IV recognizes under the name of *Angelica Radix* (*Angelica Root*) "the rhizome and roots of *Angelica atropurpurea* Linné (Fam. *Umbelliferæ*) and of other species of *Angelica*, without the presence of more than 5 per cent. of stem bases and leaves or other foreign matter. Preserve Angelica Root in air-tight containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects. Rhizomes short and thick, from 5 to 10 cm. in length, sometimes split, frequently crowned with the bases of stem and leaves; the roots are numerous, from 10 to 20 cm. in length and from 5 to 7 mm. in thickness at the base and gradually tapering to about 1 mm.; frequently twisted or braided together, externally dark gray-brown to reddish- or purplish-brown and with conspicuous, rather deep furrows; when dry breaking with a smooth fracture. On cross section, the rhizome shows a distinct pith, which is absent in the root, and both exhibit a spongy bark nearly or quite as wide as the woody zone; in the bark are radial rows of brownish canals containing oleoresin. The wood rays are finely porous and narrower than the medullary rays. The bark is rich in starch. Odor strongly aromatic; taste sweetish, pungent, aromatic, and then bitter. The powdered drug is yellowish-brown and, when examined under the microscope, exhibits numerous, mostly simple, irregularly spherical starch grains, up to 0.008 mm. in diameter, sometimes with the cleft at the center and occasionally two- or more compound; tracheæ or fragments of tracheæ, with reticulate markings or large simple pores up to 0.075 mm. in width; brownish oil canals or fragments thereof, up to 0.25 mm. in diameter, sometimes with adjoining epithelial cells; fragments of parenchyma tissue with some of the cells filled with starch; fragments of large brownish cork cells; sclerenchymatous fibers with thin walls and often with oblique markings; yellowish oil globules. Angelica Root yields not more than 8 per cent. of ash." It has a strong odor and a warm aromatic taste. The juice of the recent root is acrid, and is said to be poisonous; but the acridity is dissipated by drying. The medicinal virtues of the plant are similar to those of the garden angelica of Europe, for which it has been proposed as a substitute. It is, however, inferior to the European angelica. Its uses are similar to those of the root.

Angrecum. *Angrecum fragans* Thouars.—This is an orchidaceous plant, indigenous to the Isle of Réunion and to Mauritius, where the leaves have been long used, under the name of *faham*, for the same purposes as tea leaves. For description, see *P. J.*, 1881, 913. They have a somewhat pungent aromatic taste, and a strong and highly agreeable odor, scenting the whole apartment with a delicious perfume. Given in infusion, they appear to have an effect on the system somewhat similar to that of Chinese tea, and they have been introduced into Paris as a rival of that popular beverage. The drink is made by putting the leaves and stalks, in the proportion of fifteen grains (1 Gm.) to a teacupful, into cold water, boiling for about ten minutes, and then pouring into a closed vessel, and sweetening it when used. (*A. J. P.*, 1866, 441.)

Anhalonium.—Under the name of *Pellote* are used in Mexico for narcotic purposes, certain cacti whose tops have entered commerce under the name *of Mescal Buttons*. These were formerly believed to belong to the genus *Anhalonium*, but at present are referred to species of *Mammalaria* and of the genus *Echinocactus*, which is characterized by a flexible epidermis, its freedom from spines and tubercles and its segments not assuming the form of a projecting or leaf-like organ. (See Schumann in Engler and Prantl's *Pflanzenfamilien*, and *Reports of Missouri Botanical Gardens*, 1898.) In a mass of such cactus tops sent to the Pharmaceutical Institute of Leipzig from Mexico as pellote, experts have recognized the products of *Mammalaria fissuratus*, *M. retusus*, *Echinocactus Williamsii* Lem., and *E. Lewinii* Henn. Moreover, from *A. jourdanianum* L., Lewin obtained traces of an alkaloid (*A. E. P. P.*, xxxiv). There is little doubt but that various allied species of cactus are represented in the commercial drug. The most important of these plants are *E. Lewinii* and *E. Williamsii*, which inhabit the valley of the Rio Grande in Mexico, and are furnished with stems reaching about half an inch above the surface of the ground, surmounted by a top composed mainly of the blunt leaves of the plant, bent around a tuft, of from half an inch to an inch in diameter, composed of short, yellow-white filaments or hairs. It is this top which constitutes the *mescal button*, which is from an inch to an inch and a half in diameter, one-fourth of an inch in thickness, with a convex under surface, a texture which is brittle and hard when dry, but becomes soft when moistened, a very bitter disagreeable taste, and an odor when moist which is peculiar and disagreeable, and is especially marked in the powdered drug. According to C. H. Thompson, the buttons of *E. Lewinii* and *E. Williamsii* are readily distinguished by the fact that the surface of *E. Lewinii* is traversed by thirteen shallow narrow furrows giving the appearance of there being as many irregular or much broken ribs or obtuse ridges, while in *E. Williamsii* the furrows and ridges are eight in number and regular.

In 1888, L. Lewin separated from *E. Lewinii* an alkaloid, *anhalonine*, which has the formula $C_{12}H_{15}NO_3$, and crystallizes in small white prisms, soluble in ether, alcohol, and chloroform. Subsequently, Heffter (*Ber. d. Chem. Ges.*, 1896) separated from *E. Lewinii*, besides *anhalonine*, three alkaloids: *mescaline*, $C_{17}H_{17}NO_3$, in white needles melting at 151° C. (303.8° F.); *anhalonidine*, $C_{12}H_{15}NO_3$, fusing at 160° C. (320° F.), and *lophophorine*, $C_{13}H_{17}NO_3$. (See also *A. E. P. P.*, 1898, xl.)

Kander (*A. Pharm.*, 1899, vol. ccxxxvii) has found that in commercial mescal buttons, besides the alkaloids already mentioned, are two other bases, *pellotine* and *anhalamine*, so that Merck has offered as commercial products the following salts:

Anhalininæ Hydrochloridum cryst., ***Anhalonidinæ Hydrochloridum*** cryst., ***Lophophorinæ Hydrochloridum*** cryst., ***Mescalinæ Sulphas*** cryst., ***Pellotinæ Hydrochloridum*** cryst. According to the researches of Heffter, pellotine, $C_{13}H_{19}NO_3$, is contained exclusively in *L. Williamsii*, but as this cactus is present in most, if not all, of the commercial buttons, it was naturally found by Kander in analyzing the commercial drug. However, the correctness of the conclusion of Heffter is challenged by Merck's chemists, who, in the analysis of *L. Williamsii*, found the same quantity of the same alkaloids as is present in the true mescal button. For a description of these alkaloids see *M. R.*, 1898 and 1900. E. White (*J. P.*, xxv) obtained *mescaline*, 1.16 per cent.; *anhalonidine*, 1.16 per cent.; *anhalonine*, 0.46 per cent.; *lophophorine*, 0.14 per cent. *Anhaline*, $C_{10}H_{17}NO$, is an alkaloid crystallizing in colorless stellate prisms, which has been extracted from *L. fissuratum*.

From time immemorial the Kiowa Indians of the Rio Grande have used the mescal buttons for the purpose of producing intoxication during their religious ceremonies. Attention was first called to the peculiar cerebral action of the drug by D. W. Prentiss and Francis P. Morgan (*T. G.*, 1895), who found that from two hundred and fifteen to two hundred and thirty grains (14–15 Gm.) (four to five buttons) will produce a peculiar cerebral excitement attended with an extraordinary visual disturbance, characterized by an incessant flow of visions of infinite beauty, grandeur, and variety, of both color and form, often followed after a time by the seeing of monsters, grotesque faces, and gruesome shapes. During the intoxication there are dilatation of the pupil, muscular relaxation, and some slowing of the pulse. Loss of sense of time, partial anesthesia, weakened heart's action, great muscular relaxation, wakefulness, and in some cases nausea and vomiting also have been noted, but no distinct alteration of the respiration. These results have been confirmed by several observers.

A. Mogilewa (*A. E. P. P.*, xlix, 137) found that mescaline, anhalonidine, anhalonine, lophophorine, and pellotine acted similarly in lessening the frequency and force of the isolated frog heart, varying simply in quantitative power. The most thorough research upon the anhalonium alkaloids is that of W. E. Dixon (*J. P.*, xxv) whose report is somewhat marred by the fact that he does not state in his experiments which one of the alkaloids was employed; he simply affirmed that anhalonine and anhalonidine are identical in physiological activity, that lophophorine differs only in being more toxic, and that mescaline has a physiological action almost indistinguishable from that of its associated alkaloids. He finds that "the alkaloid" is not locally anesthetic; that increased salivation is one of the most characteristic symptoms of its action; that in therapeutic doses, in man at least, it produces constipation, but that in toxic dose it causes diarrhea and bloody stools; that its main circulatory effect is upon the cardiac muscle and contained ganglia, causing slowing of the heart and a rise of arterial pressure; that it kills by action on the respiratory centers so that in man the most serious result of an overdose is rapid, shallow breathing, with a sense of suffocation; that upon the nervous system it acts most powerfully, producing in the frog, and to a lesser degree in the mammal, increasing loss of muscular power with heightened reflexes, believed to be due to spinal stimulation. The motor nerves appear to be depressed, since they are paralyzed when the drug is applied locally to them. In experiments upon two human subjects, there was wide dilatation of the pupils, with uncertainty of gait like that of alcoholic intoxication, tremors, and heightened reflexes, although sensation was distinctly blunted. The psychical symptoms caused by the largest doses resemble somewhat those from cannabis indica. The *dose* of the alkaloid used by Dixon was three and eight-tenths grains (0.25 Gm.).

In Heffter's experiments *pellotine* was found to be physiologically feeble, one-thirteenth grain (0.005 Gm.) causing only temporary stiffness in the legs of the frog, two-thirteenths grain (0.01 Gm.) producing stiffness, heightened reflexes, strychnine-like tetanus, lasting from three to four days, ending in recovery. In man, from seven-tenths to nine-tenths of a grain (0.045–0.058 Gm.) produced only temporary sleeplessness with sense of weariness. Pilcz (*W. K. W.*, ix, 1896) has used pellotine as a calmative in fifty-eight cases of *insanity* in *doses* of from one-third to one grain (0.021–0.065 Gm.). About half the cases were markedly affected, sleep coming on in from half an hour to an hour and a half after the hypodermic injection and continuing through the night. No disagreeable results and no collapse occurred, although Langstein is said to have seen collapse following the dose of seven-tenths of a grain (0.045 Gm.).

The value of mescal buttons as a remedial agent is doubtful; it has been employed to a slight extent in various forms of *neurasthenia* and *hysteria*, and is asserted by S. F. Landry (*T. G.*, 1888) to be especially valuable in cases of *asthma*. It has also been alleged to be useful in *neuralgic* and *rheumatic affections*. Prentiss and Morgan give the *dose* of the crude drug as from seven to fifteen grains (0.45–1.0 Gm.); of the fluidextract, from ten to fifteen minims (0.6–0.9 mils); of the 10 per cent. tincture, from one to two teaspoonfuls (3.75–7.5 mils).

Aniline. *Amidobenzene. Phenylamine.* $C_6H_5NH_2$.—This is an organic base obtained from coal tar or more immediately from nitrobenzene. It was first discovered by Unverdorben, in 1826, among the products of the dry distillation of indigo, and was named by him *Krystallin*. Fritzsche, who obtained it afterwards from indigo by another process, seems to have been the first to give it the name of aniline, from the Portuguese word *anil* (indigo). In 1837, Runge obtained three volatile principles from coal tar, which he named *kyanol*, *leucol*, and *pyrrhol*. Of these, kyanol was afterwards found by Hoffmann to be identical with aniline, and leucol has been ascertained to be the same as *quinoline* (*chinoline*). Zinn prepared it in 1840 by the reduction of nitrobenzene with hydrogen and called it *benzidam*. The identity of krystallin, aniline, kyanol and benzidam and the true composition of the substance was proved by Hoffmann in 1843. Aniline did not possess any commercial importance until the discovery in 1856, by Perkins, of the first of the so-called aniline colors, Perkins' purple or mauve, when the demand for aniline became so great that it became necessary to find a method for its preparation from one of the other coal tar fractions. (See coal tar colors, page 1324.) Nitrobenzene is now the source whence most of the aniline of commerce is de-

rived. Nitrobenzene, hydrochloric acid, and iron turnings, in equal weights, are introduced into a cast iron vessel, care being taken that the heat does not rise too high, when the following reactions take place:

$$C_6H_5NO_2 + H_6 = C_6H_5NH_2 + 2H_2O$$
$$C_6H_5NH_2 + HCl = C_6H_5NH_2HCl$$

The semi-solid mass which soon forms consists principally of ferrous chloride and aniline hydrochloride. This is distilled, after the addition of milk of lime, in a large cast iron cylinder, and the distillate redistilled, the portion coming over between 175° C. (347° F.) and 190° C. (374° F.) being collected, and considered sufficiently pure for manufacturing purposes.

Properties.—Pure aniline is a thin, colorless, highly refractive fluid, of an oily appearance; but as found in commerce it is generally more or less colored, and sometimes of a deep reddish-brown. It has a peculiar, not disagreeable odor, and a pungent, aromatic, burning taste; its sp. gr. is 1.024. It solidifies at −8° C. (17.6° F.) if pure, but if impure the freezing point may be below −20° C. (−4° F.). It boils at 183°–184° C. (361.4°–363.2° F.), and its vapors are condensed unchanged. It is slightly soluble in water, but dissolves in all proportions in ether, alcohol, methyl alcohol, acetone, carbon disulphide, and the oils, fixed and volatile. As a base it is weaker than ammonia in the cold but stronger when hot. Its aqueous solution does not react with litmus or turmeric. With the acids it forms soluble and readily crystallizable salts. It is inflammable, and absorbs oxygen from the air, becoming at first yellowish, afterwards reddish, and ultimately brown. A characteristic property is that it produces instantly a deep blue or purple color when brought into contact with chlorinated lime or other hypochlorite (whence the name kyanol, of Runge). (*P. J.*, Sept., 1862, 128.) It is a derived ammonia, having the group C_6H_5 in place of a hydrogen atom of the NH_3 molecule. It is hence often called *phenylamine*. The chief value of aniline is in the manufacture of numerous derivatives, some of which are used in medicine while others form one group of the numerous so-called coal tar colors of commerce. Beautiful reds, purples, yellows, blues, and various other tints are obtained from it.

Under the name of *aniline oil* a liquid is to be found in commerce which consists of a mixture of aniline, toluidine, xylidine, cumidine, and varying quantities of by-products found in the "tailings"; the boiling point ranges between 180° C. (356° F.) and 210° C. (410° F.), and the sp. gr. is also variable; it is used as a solvent for rubber, copal, etc. Certain of the aniline or coal tar dyes possess properties which have led to their employment in medicine. (See under their various names.)

Medicinal Properties.—The symptoms which are produced by the inhalation or ingestion of aniline are great prostration, heaviness in the head, giddiness, vomiting, violent neuralgic pains, and, if the dose has been large enough, cyanosis, coma with dilatation of the pupils, excessive perspiration, loss of reflexes and of voluntary movement, hurried weak pulse, rapid or irregular respiration, hemoglobinuria, a peculiar discoloration of the skin, and, if the patient survives sufficiently long, jaundice with great increase in the biliary pigment of the urine. At the autopsy reported by Müller (*A. J. P.*, 1887), in a woman killed by the swallowing of about a fluidounce (30 mils) of aniline, the blood was chocolate brown, and gave the spectrum of methemoglobin; the urine was free from sugar, albumin, or blood, but contained paramidophenol, and its distillates gave aniline reactions. The hemoglobinuria is evidently connected with an extraordinary destruction of the red blood corpuscles, for in the case reported by Dehio (*A. J. P.*, 1888), in a woman who had taken one hundred and fifty grains (9.8 Gm.) of aniline, the red blood corpuscles fell from normal, 5,000,000 per mil to 2,700,000 on the seventh, and 1,400,000 on the eleventh day.

The violent local effects which have been noticed as produced by some aniline dyes have probably been due to the presence of arsenic, which is used in their production and may remain as a contamination. A preferable designation for these colors of synthetic origin is *coal tar colors.* (See p. 1324.) The use of artificial coloring substances is now prohibited in some classes of materials and restricted in others to a limited few, which are known to be harmless and are required to be certified as to the absence of injurious constituents. (See *Chem. Ztg.*, 1910, No. 14; also LaWall, *Proc. Penna. Pharm. Assoc.*, 1904, 92, for methods of detection.) For list of colors permitted by the United States Government, see Food Inspection Decisions in the preliminary part of this work.

Aniline Blue. *Triphenyl-rosaniline, Toluidine Blue. Pure Blue. Water Blue.*—This dye-stuff is said to possess anti-malarial properties similar to those of methylene blue. The *dose* is five grains (0.3 Gm.) in capsules three times a day.

Aniline Sulphate, $(C_6H_5NH_2)_2H_2SO_4$, occurs in white crystals, soluble in water and alcohol. It is used as a nervine in *chorea* and *epilepsy. Dose,* three-quarters to one and one-half grains (0.05–0.1 Gm.) three times daily. Maximum *dose,* three grains (0.2 Gm.) with the daily maximum dose of six grains (0.4 Gm.).

Anilipyrine.—Gilbert and Yvon have given this name to a substance obtained by the melting together of one part of acetanilide and two parts of antipyrine. Anilipyrine is stated by Gilbert and Yvon to be extremely soluble in water and to be toxically very feeble. The fatal dose for the guinea-pig is 1.8 Gm. per kilo. Anilipyrine has been used by its introducers as an antipyretic and analgesic in *migraine, neuralgia, rheumatism,* etc. The *dose* is eight grains (0.5 Gm.) from two to four times a day.

Animal Charcoal. *Spodium. Ebur Ustum. Bone Black. Ivory Black. Charbon Animal Ordinaire,* Fr. Cod. *Noir Animal Pulvérisé, Noir d'os,* Fr. *Thierische Kohle, Knochenkohle, Beinschwarz, Thierkohle,* G. *Nero di ossa, Carbone animale,* It. *Carbon animal, Carbon de hueso,* Sp. "Charcoal prepared from bone." *U. S. VIII.*—Animal charcoal was not retained in the United States Pharmacopœia IX.

The animal charcoal employed in pharmacy and the arts is usually obtained from bones, by subjecting them to a red heat in close vessels. The residue of the ignition is a black matter, which when reduced to powder forms *bone black,* sometimes incorrectly called *ivory black.*

In manufacturing bone black, the bones, first treated with steam to separate the fat, are subjected to destructive distillation in iron cylinders connected with vessels which receive the ammoniacal liquor, called *bone spirit,* together with a dark tarry liquid (*bone oil*), this being a second-

ary product of the operation. When the distillate ceases to come over, the residue is charred bone, or bone black. Bone consists of animal matter with calcium phosphate and carbonate. In consequence of the decomposition of the animal matter involved in this destructive distillation, the nitrogen and hydrogen, united as ammonia, and a part of the charcoal, in the form of carbon dioxide, distil over, while the remainder of the charcoal is left in the cylinder, intermingled with the calcareous salts. Diess, of Paris, proposes carbon disulphide as a solvent for the fat of bones, as it furnishes a larger and better product of fat, and renders the bones fitter for producing a good bone black. This form of animal charcoal necessarily contains calcium phosphate and carbonate. Animal charcoal occurs in "dull black, granular fragments, or a dull black powder, odorless, nearly tasteless, and insoluble in water or alcohol. When ignited, it leaves a grayish or yellowish-white ash, amounting to about 85 per cent. of the original weight of the portion taken, which should have been previously dried at 120° to 125° C. (248°–257° F.) to a constant weight. The ash should be soluble in hydrochloric acid with the aid of heat, leaving not more than a trifling residue. If 1 Gm. of Animal Charcoal be boiled for several minutes with a mixture of 3 mils of potassium hydroxide T.S. and 5 mils of water the filtrate should be colorless or nearly so (evidence of *complete carbonization*)." *U. S. VIII.* It is more dense and less combustible than vegetable charcoal; from which, moreover, it may be distinguished by burning a small portion of it on a red hot iron, when it will leave a residue imperfectly acted on by sulphuric acid, whereas the ashes from vegetable charcoal readily dissolve in this acid, forming a bitterish solution.

Bone black consists of about 90 per cent. of calcium phosphate and carbonate, and 10 per cent. of carbon.

The decolorizing power of vegetable charcoal was first noticed by Lowitz, of St. Petersburg; and that of animal charcoal by Figuier, of Montpellier, in 1811. In 1822 the subject was ably investigated by Bussy, Payen, and Desfosses. The power is generally communicated to charcoal by igniting it in close vessels, but not always. The kind of charcoal, for example, obtained from substances which undergo fusion during carbonization scarcely possesses the property, even though it may be afterwards finely pulverized. The property in question is possessed to a certain extent by wood charcoal, but is developed in it in a much greater degree by burning it with some chemical substance, which may have the effect of reducing it to an extreme degree of fineness. The most powerful of all the charcoals for discharging colors are those obtained from certain animal matters, such as dried blood, hair, etc., by first carbonizing them in connection with potassium carbonate, and then washing the product with water. Charcoal thus prepared seems to be reduced to a state of extremely minute division, and is, therefore, very porous. The next most powerful decolorizing charcoal is *bone black*, in which the separation of the carbonaceous particles is effected by the calcium phosphate present in the bone.

Animal charcoal by no means invariably possesses the decolorizing property, as this depends upon its peculiar state of aggregation. If pure animal matter (soft tissues) is carbonized, it usually enters into fusion, and, from the gaseous matter which is extricated, becomes porous and cellular. The charcoal formed has generally a metallic luster, and a color resembling that of black lead. It has, however, little or no decolorizing power, even though finely pulverized.

In the manufacture of potassium ferrocyanide there is obtained a fine black sediment, which has a powerful decolorizing action; this is sometimes attributed to the organic nitrogenous character of the material from which it is made.

In order to determine the commercial value of animal charcoal, Corenwinder has proposed to ascertain its power of absorbing lime from a solution of calcium saccharate of determinate strength. The value is in proportion to the absorbing power of the charcoal. A given weight of the charcoal to be tested is left in contact, for an hour, with a given volume of the solution of the saccharate, taken in excess. The liquid is then filtered, and a small measure of it saturated with diluted sulphuric acid of known strength. The less the acid necessary for this purpose, the greater the amount of lime absorbed, and the better the animal charcoal. (*Chem. Gaz.*, 1854; *Scientific American*, April 22, 1876; *A. Pharm.*, 1887; *Proc. A. Ph. A.*, 1887.) See also Laval's investigations, *P. J.*, 1900, 214. Dupuy found that the addition of a few grains of animal charcoal to a few mils of cold fresh tincture of guaiacum immediately causes the development of a blue color, while wood charcoal does not give this reaction. (*P. J.*, 1897, 190.)

Spent animal charcoal, which has been used by the sugar refiners, may have its decolorizing power restored by calcination, which destroys the organic matters that have become fixed in it, and it is stated that it may be submitted to this process twenty times before becoming unfit for use, although this depends upon the amount of calcium salts it takes up from the raw sugars, beet sugars using up the black faster than sugars from the cane. According to Pelouze, the same object may be accomplished by subjecting it to a weak solution of potassium or sodium carbonate. In removing the coloring matter, the alkaline solution becomes yellow. After its action the animal charcoal must be carefully washed, first with boiling water, and afterwards with acidulated water. A process devised by Leplay and Cuisinier is probably more effectual. The charcoal, without being removed from the cylinders, is thoroughly washed, treated by steam to remove viscous substances, and then percolated successively, (1) by a weak alkaline solution, which removes salts and some coloring matter; (2) by weak hydrochloric acid, which, in removing a certain amount of salts of lime, liberates coloring matter; (3) again with a weak alkaline solution, to carry off the remaining coloring matter; and (4) lastly by a solution of calcium biphosphate, by which the decolorizing power of the charcoal is restored.

Animal charcoal is capable of taking the bitter principles from infusions and tinctures, and iodine from liquids which contain it in solution. Its power, however, of acting on solutions and chemical compounds is stated by Warington and Weppen to be more decided in its purified condition. (See *Carbo Animalis Purificatus*, page 1254; see also *Ephem.*, 1885, p. 721.) On the other hand, Carswell (*P. J.*, 1893, 615) believes that the purification of animal charcoal is based on erroneous conclusions, as charcoal possesses no inherent powers of decolorization but the latter depends partly on the aggregation of cellular spaces and chiefly on the mineral constituents.

Animal charcoal is used in pharmacy for de-

colorizing vegetable principles, such as gallic acid, quinine, morphine, veratrine, etc., and in the arts, principally for clarifying syrups in sugar refining, for depriving spirits distilled from grain of the penetrating impurity, called *fusel oil*, which imparts to them an unpleasant odor and taste, as first distilled, and for the filtration of petroleum residues in the manufacture of petrolatum and petroleum jellies. (See *Petrolatum*.) The manner in which it is used as a decolorizer is to mix it with the substance to be decolorized, and to allow the mixture to stand for some time. The charcoal unites with the coloring matter, and the solution by filtration is obtained white and transparent. Its use, however, in decolorizing the alkaloids and other vegetable principles, no doubt causes a loss by absorption, since it has been shown by the experiments of Lebourdais, mentioned under the head of purified animal charcoal, that several of these principles may be obtained by the sole action of charcoal. According to Guthe, a German chemist, bone charcoal, without purification, is to be preferred as a decolorizer in all cases in which the calcareous salts exert no injurious effect. Voilé uses animal charcoal as an absorbent in a pill excipient for making creosote and croton oil pills.

Because of its power in absorbing many toxic principles, animal charcoal has been recommended as an antidote in the treatment of various alkaloidal and mineral *poisonings* and, according to Secheyron (*Revue Internationale de Médicine*, 1909, p. 120), is especially to be recommended in *mushroom poisoning*. For this purpose a tablespoonful stirred up in water may be given at a dose. Because of its absorptive powers it has also been recommended by Adler (*W. K. W.*, 1912) in *enteritis* and by Pribran (*Pr. M. W.*, 1913) in *gastric flatulence*. For these latter conditions it may be administered in teaspoonful doses.

Animal Charcoal, Purified. *Carbo Animalis Purificatus. U. S. VIII. Charbon animal purifié*, Fr. Cod. *Gereinigte Knochenkhole*, G. *Carbone di ossa depurato*, It.—For a process of purifying animal charcoal see page 292, *U. S. D.*, 19th edition.

Animal charcoal, as it is made by charring bones, necessarily contains bone phosphate and calcium carbonate, the presence of which does no harm in some decolorizing operations; but in delicate chemical processes these salts may be dissolved or decomposed, and thus become a source of impurity. It is on this account that animal charcoal requires to be purified from its calcareous salts; and this is accomplished by diluted hydrochloric acid, which dissolves the phosphate and decomposes the carbonate. According to Stenhouse, aluminized vegetable charcoal is equally efficacious with purified animal charcoal as a decolorizer.

Properties.—Purified animal charcoal is "a dull black powder, odorless, tasteless, and insoluble in water, alcohol, or other solvents. If 2 Gm. of the powder be ignited at a red heat with free access of air in a broad, shallow porcelain or platinum dish, it should not leave a residue weighing more than 0.08 Gm., or 4 per cent. of the original weight (limit of *silicates* and *other fixed inorganic matter*). If 1 Gm. of the powder be boiled with a mixture of 3 mils of potassium hydroxide T.S. and 5 mils of water during three minutes, the filtrate should be colorless (evidence of *complete carbonization*)." *U. S. VIII.*

It has been shown by Robert Warington that bitter vegetable substances, including the organic alkalies, are removed from solution by passing through purified animal charcoal, especially when the action is assisted by heat. Weppen finds that it also removes resins from tinctures, tannic acid and bitter principles from infusions, and certain metallic salts from their solutions. Purified animal charcoal, thus employed, has been resorted to by Lebourdais as an agent for obtaining the active principles of plants. A decoction or infusion of the plant is either boiled with or filtered through the charcoal, which takes up, more or less completely, the bitter and coloring principles. The charcoal, after having been washed and dried, is treated with boiling alcohol, which dissolves the principles taken up. Finally, the alcohol is distilled off, and the principles are obtained in a separate state. In this way digitalin, ilicin, scillitin, columbin, colocynthin, arnicine, strychnine, quinine, and other principles have been obtained by Lebourdais. (*Chem. Gaz.*, Nov. 15, 1848.) (In relation to the method of Lebourdais, see a paper by J. S. Cobb, in *A. J. P.*, 1851.) A. B. Garrod proposed purified animal charcoal as an antidote to vegetable and animal poisons, with which it appears to combine. According to his experiments, common bone black has not one-fifth of the power possessed by the purified substance, and vegetable charcoal and lamp-black are nearly or quite useless. The amount of the antidote proposed by Garrod is half an ounce for each grain of a vegetable alkaloid. Alfred Taylor deemed the results of Garrod inconclusive. B. H. Rand made some interesting observations in relation to the antidotal powers of purified animal charcoal, and proved that poisonous doses of the strongest vegetable poisons may be swallowed with impunity if mixed with that substance.

In using animal charcoal for decolorizing active vegetable principles much loss is often incurred by the absorption of those principles by the charcoal.

Animé. *Gum Animé.*—The substance known at present by the name of animé is a resin supposed to be derived from the *Hymenæa courbaril* L., a leguminous tree of South America, although this origin was denied by Hayne. According to W. Hamilton, the resin exudes from wounds in the bark, and is found also underneath the surface of the ground, between the principal roots. It is in small, irregular pieces of a pale lemon-yellow color, sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle and pulverizable, with a shining fracture, a weak but agreeable odor, and a mild, resinous taste. It softens in the mouth, adheres to the fingers when in powder, and readily melts with heat, diffusing its agreeable odor in an increased degree. It consists of two resins, one soluble, the other insoluble, in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker color, less transparent, and with small cavities in the interior, in other respects resembling the preceding. Another variety is the East Indian, supposed to be derived from *Vateria indica*, L. (Fam. *Dipterocarpaceæ*), but this never reaches American commerce. According to W. C. Ondaatje, the bark of this plant is in daily use by the natives of Ceylon to arrest the alcoholic fermentation of the juice of the Jaggery palm, *Caryota urens*, L., a favorite beverage. (*P. J.*, 1883, 818.) Animé formerly entered into the composition of various ointments and plasters; but it is now used only as incense, or in the preparation of varnishes. The Brazilians employ it internally in *diseases of the lungs*.

Anisic Acid. *Paramethoxybenzoic Acid. Dra-*

conic Acid. $C_6H_4.OCH_3.COOH$.—It is prepared from anisic aldehyde or by oxidization from *p-kresolmethyl ether.* It forms colorless crystals which are almost insoluble in cold water and slightly soluble in alcohol and ether. As an antiseptic it is alleged to have marked power and it is also used as an antirheumatic and antipyretic. *Dose,* five to fifteen grains (0.32–1.0 Gm.).

Anisodus. *Anisodus luridus* Link and Otto. (*Scopolia lurida* Dun.)—This is a Himalayan solanaceous plant in which Siebert has found *atropine* and *hyoscyamine.* (*A. Pharm.,* Feb., 1890; *P. J.,* March, 1890.)

Anisole.—This name has been applied to the *methyl ether of phenol* because of the fact that it was at one time manufactured from anisic acid. It has been found by Professor Fraenkel to be an active agent against *lice* and other body vermin.

Annatto. *Orleana. Annotta. Arnotta. Terre de la Nouvelle-Orléans,* Fr. *Orellana, Orlean,* G.—The coloring substance called *annatto, arnotta* or *roucou,* is the reddish pulp surrounding the seeds in the fruit of *Bixa orellana* L. (Fam. *Bixaceæ*), a middle-sized tree native to Northern South America, but widely cultivated in tropical Asia and Africa. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to settle. The mass which remains is dried and formed into flat cakes or cylindrical rolls. Another mode is to bruise the seeds, mix them with water, and allow the mixture to ferment. The coloring matter is deposited during the fermentation, after which it is removed and dried. In commerce there are two kinds of annatto, the Spanish or Brazilian, and the French, the former coming in baskets from Brazil, the latter in casks from French Guiana. The French, which is also called *flag annatto,* has a disagreeable odor, probably from having been prepared by the fermenting process in which urine is sometimes used; but is superior, as a dye stuff, to the Spanish, which is without any disagreeable odor. Annatto is of a brownish-red color, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odor, and a disagreeable, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow color, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. The South American Indians are said to produce directly from the annatto seeds, without fermentation, a color similar to and almost as brilliant as carmine. (*P. J.,* April, 1903.) For a proximate analysis of the leaves see *Ap. Ztg.,* 1899, p. 35. It contains a peculiar coloring principle, to which Preisser, its discoverer, gave the name of *bixin.* This has the formula $C_{28}H_{34}O_5$, and when pure is a dark, red, somewhat crystalline substance. According to Van Hasselt, bixin has the composition $C_{29}H_{34}O_5$, but Heiduschka and Riffart believe that the correct formula is $C_{28}H_{34}O_5$. (*A. Pharm.,* 1911, No. 1, 39.) It is accompanied by a yellow coloring matter, *orellin.* A coloring matter found in the root of *Escobedia scabrifolia,* a plant growing in tropical America, is used by the Mexicans in coloring fats and butter yellow. (*S. W. P.,* 1912, No. 18, 260.) The chief uses to which annatto is applied are for dyeing silk and cotton orange-yellow, and for coloring cheese and butter. The color, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is employed to color ointments and plasters, and has occasionally been substituted for saffron. It is frequently adulterated with red ochre, powdered bricks, colcothar, farinaceous substances, chalk, calcium sulphate, turmeric, etc. The mineral substances, if present, will be left behind when the annatto is burned. *Tincture of annatto* is made by extracting 100 parts of annatto with 100 parts of water containing 1½ per cent. of potassium carbonate, and evaporating to 60 parts, mixing with 12 parts of alcohol and filtering.

Anona.—The seeds of *A. squamosa,* L., *Sugar Apple* or *Sweet Sop* of the West and East Indies, are said to be poisonous and to be used to kill lice, while the bark is a drastic cathartic. The seeds of *A. muricata,* L., *A. palustris,* L., and *A. spinescens,* Mart., are employed to poison fish and to exterminate destructive insects. (*Ph. Rev.,* Oct., 1896.)

Anthrakokali.—For an account of this preparation, which was introduced by Polya, see 16th ed. *U. S. D.,* p. 1711.

Anthrarobin. *Anthro-arobin. Leucoalizarin.*

$$C_6H_4\begin{cases}C(OH)\\ |\\ CH\end{cases}C_6H_2(OH)_2$$

—This substance, which is produced from commercial alizarin by reduction, was first described by Liebermann (*Ber. d. Chem. Ges.,* 1888), and proposed as a substitute for chrysarobin. It is a yellowish-white granular powder, almost insoluble in water and acidulated solutions, sparingly soluble in chloroform and ether, and readily soluble in alcohol and weak alkaline solutions. It mixes readily with fats to form ointments. It is a powerful reducing agent, which seems to be less toxic than chrysarobin, and probably equally effective in the treatment of *diseases of the skin,* it having been used by G. Behrend, E. B. Bronson, Köbner, and other clinicians, with asserted advantage in those diseases for which chrysarobin is employed. In alkaline solution anthrarobin readily absorbs oxygen and is reconverted into the blue alizarin. It is incompatible with hydrogen dioxide, potassium permanganate and other oxidizing agents. Behrend recommends the following. *Solution of anthrarobin:* anthrarobin, 10 parts; borax, 8 parts; water, 80 parts. *Glycerite of anthrarobin:* anthrarobin, 10 parts; glycerin, 80 parts. (*Th. M.,* 1888.) As a topical application, the ointment or the alcoholic solution (each 10 per cent.) may be used.

Anthrasol. *N. N. R.* 1916. *Colorless Coal Tar.*—Anthrasol is coal tar freed from bases such as pyridin and chinoline by acid treatment and from pitch by distillation. The distillate is purified to remove coloring principles and juniper tar is added to prevent separation of solid constituents. Oil of peppermint is added to correct the odor. It is a thin, mobile, light-yellow oil which stains neither skin nor fabric. Anthrasol is an antiseptic and parasiticide. Like ordinary coal tar it allays irritation of the skin but is said neither to obstruct the follicles nor to favor the development of *acne.* It is used in ointments in strengths varying from 5 to 30 per cent. A glycerin soap containing 20 per cent. of anthrasol is marketed under the trade name of *Anthrasolin.*

Anthriscus. *Anthriscus cerefolium* (L.) Hoffm. (*Chærophyllum sativum* Lam. *Scandix cerefolium,* L.), *Chervil.*—An annual European plant of the Fam. *Umbelliferæ,* cultivated in gardens as a pot-

herb, and naturalized in Eastern and Southern Pennsylvania. It has a strong agreeable odor, and a pungent, slightly bitterish taste. It contains a volatile oil of very feeble medicinal power, but it has been used as an emmenagogue and diuretic.

Antiaris.—Among the Asiatic arrow poisons one of the most important, which has long been used by the natives of Java and other East Indian islands under the name of *Upas antiar*, is a gum-resinous exudation obtained from the *Antiaris toxicaria* Lesch., a large tree belonging to the *Urticaceæ*, growing in Java, Celebes, and the neighboring islands. Like certain species of *Rhus*, this plant exhales a volatile poison which very unpleasantly affects some of those who approach it, causing eruptions upon the skin attended with much swelling; hence the fable of the *deadly upas tree*. The juice is mixed with various substances to give it due consistency. Whether taken internally or introduced into the system through a wound, upas acts with extreme violence, producing vomiting, great prostration, a feeble, irregular pulse, involuntary evacuations, and convulsive movements, which are soon followed by death.

Pelletier and Caventou obtained from it a glucoside, *antiarin*, crystallizable, soluble in water and alcohol, but scarcely so in ether, and of the formula $C_{14}H_{20}O_5$. According to Kiliani (*Ber. d. Chem. Ges.*, 1910, p. 3574), there are two glucosides, namely, *alpha- and beta-antiarin*. For the first of these he suggests the formula $C_{27}H_{42}O_{10} + 4H_2O$, while the formula for the second is uncertain, but may be $C_{22}H_{30}O_8$. Antiarin is a muscle poison, producing first strong fibrillary contractions of the voluntary muscles, followed by a rapid decrease in irritability and finally paralysis, the sarcolemma of the muscles and not the motor nerve endings being the part attacked. It also belongs to the digitalis group of cardiac stimulants, raising the blood pressure at first, and finally arresting the heart in systole. According to Stockman, antiarin diminishes the irritability of the peripheral vagi and stimulates the vasomotor centers. H. W. Bettink claims (*Ned. Tijdschr. v. Pharm.*) that besides antiarin there are present in *Upas antiar* two other active principles, *œpaïn* and *toxicarine*. Headborn (*A. E. P. P.*, 1901, xlv) states that *antiarigenin*, a derivative of antiarin, is more powerful than antiarin itself.

Antihydropin. *Pulvis Taracanæ.*—The powdered Russian *cockroaches* (*Blatta lapponica, Blatta orientalis*) are asserted, in the dose of from ten to fifteen grains (0.65–1.0 Gm.), to be actively diuretic and useful in *dropsy*. Bogomolow (*Ph. Cb.*, July, 1879) found in them a crystalline principle, *antihydropin*, or *taracanin*. L. Reuter (*A. Pharm.*, 1889, 868) affirms that the discredit into which cockroaches have fallen is due to the indifferent quality of the powdered insects in the market, and gives tests for their purity.

Antiluetin. — *Potassium-ammonium-antimonic bitartrate*, $SbO(C_4H_4O_6)_2K(NH_4)_2.H_2O$, has been used by Tsuzuki (*D. M. W.*, 1913, p. 825) in the treatment of *syphilis*. The beginning dose he used was two-fifths of a grain (0.025 Gm.) increased rapidly to three-fourths of a grain (0.05 Gm.).

Antimony Arsenate.—This is a heavy, snow-white powder, containing 80 per cent. antimonic oxide and 20 per cent. arsenic acid (Merck). *Antimony arsenite*, on the other hand, is said to contain equal parts of the two ingredients, arsenous acid and antimonic oxide. It is stated that antimony arsenate is used in Russia as an alterative in *doses* of one-fiftieth of a grain (0.0013 Gm.) four times a day. (*A. J. P.*, xliv, 301.)

Antimony Crocus. *Crocus of Antimony. Saffron of Antimony.*—This compound is formed during the deflagration of a mixture of equal weights of antimony trisulphide and potassium nitrate, to which one-twelfth of hydrochloric acid has been added. Fused crocus of antimony is in masses of a liver-brown color; the unfused is a saffron-brown insoluble powder, containing about four-fifths of trioxide, and one-fifth of trisulphide. It was formerly used in making tartar emetic.

Antimony, Diaphoretic. *Antimonium Diaphoreticum. Potassii Biantimonias. Antimoine diaphorétique lavé*, Fr.—This compound may be formed by deflagrating in a crucible, and keeping red hot for fifteen minutes, a mixture of pure antimony with three times its weight of potassium nitrate. The product, washed with water and dried, is *washed diaphoretic antimony*. For improved process, see 14th edition of *U. S. D.*, p. 1640. *Dose*, from one-half to two drachms (1.9–7.7 Gm.). This form of antimony is weak, variable, and rarely used.

Antimony Glass. *Vitrum Antimonii.*—This is prepared from antimony trisulphide by a partial roasting and subsequent fusion. Glass of antimony is an active antimonial; but, owing to its variable composition and unequal operation, it is very seldom used. For further information concerning this substance, see *U. S. D.*, 19th ed., p. 1391.

Antimony Aniline Tartrate. $SbO.C_6H_5NH_2.C_4H_4O_6$.—According to Loweran, this occurs in colorless, yellow crystals, soluble in water, containing 22 per cent. of antimony. Although antimony and potassium tartrate has been used both experimentally and clinically in the treatment of trypanosome infections, its high toxicity has discouraged the hope of its proving a useful therapeutic agent. The antimony and aniline tartrate, which was first prepared by C. S. Evans, was found by Loweran (*C. R. A. S.*, 1909, p. 546) to be much less toxic to the higher animals and to be an efficient trypanocide in guinea-pigs. Thiroux has used it clinically in the treatment of *sleeping sickness* and, although it is as yet too soon to say definitely concerning its value, his results are at least encouraging. He injected it intravenously in *doses* of one-fourth of a grain (0.15 Gm.).

Antimony Iodide. SbI_3. *Antimonii Iodidum. Antimony Triiodide* or *Teriodide.*—According to W. Copney, of London, this iodide may be conveniently prepared by gently heating, in a Florence flask, metallic antimony and iodine, in the proportion of one part to three. The elements combine with sudden heat and liquefaction, and, upon the withdrawal of the heat, the iodide formed solidifies, and is removed by breaking the flask. Antimony iodide, as thus prepared, forms a somewhat crystalline, foliated mass, which, when pulverized, yields a deep orange-red powder. By the action of water it is decomposed. It has been tried as an alterative in *doses* varying from one-fourth to one-half grain (0.016–0.03 Gm.), given in pill.

Antimony Sulphide. *Antimonium Nigrum*, Br. 1864. *Black Antimony. Japanese Antimony. Antimony needle. Prepared Sulphuret of Antimony, Stibium Sulfuratum Crudum et Lœvigatum, Antimonium Crudum, Sulfuretum Stibicum; Artificial Sulphuret of Antimony; Sulfure d'Antimoine du commerce*, Fr. Cod. *Antimoine sulfuré, Antimoine cru*, Fr. *Stibium sulfuratum nigrum*, P. G. *Schwefelantimon, Schwefelspiessglanz*, G. *Anti-*

moino crudo, Sp. *Antimonii Sulphidum*, U. S. 1890. *Antimony Trisulphide.* Sb_2S_3; 334.09.—"Native antimony sulphide, purified by fusion and as nearly free from arsenic as possible." *U. S.*, 1890.

Preparation.—The antimony sulphide which is found in commerce is obtained from the native sulphide, called *antimony ore*, by different processes of purification.

Much of the "Black Antimony" of commerce has been shown by Warder to contain no antimony whatever, but to be simply powdered coal and marble, and such can be easily distinguished by the fact that a dry, tared one-ounce bottle will hold, after shaking down, two and a quarter ounces of powdered black antimony, but only one and a quarter ounces of powdered coal. (*Proc. A. Ph. A.*, 1885, 479; see also S. W. McKeown, *Proc. Ohio State Pharm. Assoc.*, 1885.) Antimony sulphide should never be triturated with a strong oxidizing agent as an explosion is liable to occur. When exposed to the air it is partially converted into the oxide.

Properties.—Antimony sulphide is mostly prepared in France and Germany. It is called, in commerce, antimony, or *crude antimony*, and occurs in fused conical masses, denominated "loaves." "Steel-gray masses of a metallic luster and a striated crystalline fracture, forming a black or grayish-black, lusterless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide." *U. S.*, 1890.

Uses.—This preparation is very uncertain in its operation, and ought not to be used in practical medicine. It has, however, been employed as a diaphoretic and alterative in *scrofula, glandular obstructions, cutaneous diseases*, and *chronic rheumatism*. It is used in the United States solely in veterinary practice. The *dose* for a horse or cow is from ten to thirty grains (0.65–2.0 Gm.), to be given in powder or bolus. For further information concerning antimony sulphide, see *U. S. D.*, 19th ed., p. 1391–1392.

Antimony Sulphide, Purified. *Antimonium Nigrum Purificatum*, Br. 1898. *Antimonious Sulphide. Antimonii Sulphidum Purificatum*, U. S. 1890. *Purified black Antimony. Sulfure d'Antimoine pur*, Fr. Cod. *Gereinigtes Schwefelantimon*, G. *Trisolfuro di antimonio depurato*, It.—"Native antimonious sulphide, Sb_2S_3, from which siliceous matter has been removed by fusion, reduced to fine powder, and, if any salt of arsenium be present, purified by digesting with half its weight of solution of ammonia for several days, washing and drying." *Br.* The process of the U. S. P., 1890, for its purification was as follows: "Antimony Sulphide, *one hundred grammes* [or 3 ounces av., 231 grains]; Ammonia Water, *fifty mils* [or 1 fluidounce, 5½ fluidrachms]; Water, *a sufficient quantity*. Reduce the antimony sulphide to a very fine powder. Separate the coarser particles by elutriation, and, when the finely-divided sulphide has been deposited, pour off the water, add the ammonia water, and macerate for five days in a well-closed vessel, agitating the mixture frequently. Then let the powder settle, pour off the ammonia water, and wash the residue by repeated affusion and decantation of water. Finally dry the product by the aid of a gentle heat."

These processes are intended to furnish a black antimony sulphide better fitted for the manufacture of the official preparations of antimony and for internal administration. Copper, a common impurity in the crude sulphide, is rendered soluble by the ammonia water, while the subsequent washing and decantation effectually remove all soluble impurities.

It is "a heavy, grayish-black, lusterless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At a temperature below a red heat it fuses to a dark brown liquid." *U. S.*, 1890.

The official tests were as follows: "If 1 Gm. of the Sulphide be digested, and finally boiled, with 10 mils of hydrochloric acid, it should dissolve without leaving more than 1 per cent. of residue. This acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which is soluble in a solution of tartaric acid. After the separation of the precipitate by filtration, the filtrate yields an orange-red precipitate with hydrogen sulphide test-solution. If 2 Gm. of the Sulphide be mixed and cautiously ignited, in a porcelain crucible, with 8 Gm. of pure sodium nitrate, and, after cooling, the fused mass be boiled with 25 mils of water, there will remain a residue which should be white or nearly so, and not yellowish nor brownish (absence of *other metallic sulphides*). On boiling the filtrate separated from the last-mentioned residue with a slight excess of nitric acid, until no more nitrous vapors are evolved, then dissolving in it 0.1 Gm. of silver nitrate, filtering again if necessary, and cautiously pouring a few drops of ammonia water on top, not more than a white cloud, but no red or reddish precipitate, should appear at the line of contact of the two liquids (absence of more than about 0.1 per cent. of *arsenic*)." *U. S.*, 1890. "A grayish-black crystalline powder decomposed on boiling with *hydrochloric acid*, an almost clear solution being formed and hydrogen sulphide escaping. The solution affords the reactions characteristic of antimony. It should not yield more than slight characteristic reactions with the tests for arsenium." *Br.*, 1898. This preparation is not used in medical practice, but is used in the manufacture of sulphurated antimony (see p. 154).

Antimony Trichloride. *Butter of Antimony.* $SbCl_3$.—Prepared by subliming antimony sulphide with mercuric chloride, by the action of dry chlorine on the sulphide or metal, or by dissolving the sulphide in hydrochloric acid and concentrating the solution of the chloride; in the latter method the product is usually colored by contamination with iron, but by distillation the pure chloride will finally pass over, the distillate solidifying in a mass of fine white crystals. Antimony trichloride is a deliquescent, soft mass, known as butter of antimony, which melts at 72° C. (161.6° F.) and boils at 223° C. (433.4° F.). It is very hygroscopic and corrosive. The addition of water produces the oxychloride known, when dry, as *powder of Algaroth*. A solution was recognized in the Br. Ph., 1885, and is used in medicine as a caustic. McDonald and Hill have improved the formula for *solution of chloride of antimony* by dissolving 132 grains of antimonous chloride in 3 fluidrachms of hydrochloric acid and sufficient distilled water to make 1 fluidounce. If it is desirable to have a tinted solution, add 15 grains of ferric chloride to each fluidounce. (*P. J.*, 1908, 86.) It is extensively used to give a bronze surface to iron and steel ware.

Antinonnin. *Sodium ortho-di-nitro-cresolate.*—A yellowish, odorless, non-volatile paste said to be actively germicidal, odorless, and poisonous. On account of its being very effective and inexpensive, it has been highly recommended for spraying plants, etc., when attacked with mildew or other vegetable parasites: 1 to 2000 in soap solution may be used. It produces bright yellow stains upon fabrics, etc.

Antinosin. *Sodium tetra-iodophenolphthalein.* $(C_6H_2I_2ONa)_2C.O.C_6H_4O$.—A blue powder, soluble in water and employed as a succedaneum for iodoform as a surgical antiseptic in 5 to 10 per cent. wash. (See also *Nosophen.*)

Antipyrine Benzoate.—*Benzopyrine,* $C_{11}H_{12}N_2O.HC_6H_5O_2$, made by adding antipyrine to a boiling solution of benzoic acid. It is in the form of a yellow liquid, practically insoluble in hot and cold water, but soluble in alcohol and ether.

Antipyrine Tannate.—This is described as a yellow powder, insoluble in water, soluble in alcohol, and containing 37 per cent. of antipyrine. It is stated that it may be made by adding concentrated aqueous solutions of its constituents in the proportion of fifty parts of antipyrine to twenty-eight and a half parts of tannic acid. It has been specially recommended on account of its tastelessness, but is probably not an eligible preparation. Its incompatibilities are numerous, including those of both antipyrine and tannin.

Antisepsin. *Asepsin. Monobromacetanilide. Parabromacetanilide.* $C_6H_4Br.NH(C_2H_3O)$.—This substance has been used by Cattani as an antipyretic and analgesic (*G. M. P.*, 1890), but as such seems to be dangerous. Cattani affirms it to be a valuable antiseptic. *Dose,* from two to eight grains (0.12–0.5 Gm.).

Another compound, called antisepsin (or *antiseptin*), has been exploited as *iodoboro-thymolate of zinc,* which, according to Squibb, is a mixture of zinc sulphate, boric acid, zinc iodide, and thymol. (*Ph. Post,* 1893, 106.)

Antiseptol.—Under this name Yvon has recommended *cinchonine iodosulphate* as a substitute for iodoform. It contains 50 per cent. of iodine. For method of making this salt, see *U. S. D.*, 19th ed., p. 1392.

Antispasmin. $C_{23}H_{36}NO_8Na + 3C_6H_4(OH)COONa$.—In this compound 1 molecule of *narceine-sodium* is considered to have united with 3 molecules of sodium salicylate. This white, slightly hygroscopic powder contains about 50 per cent. of narceine, and is said to have the advantage over the other narceine preparations of readily forming with water a fairly permanent solution. According to Demme, it is a valuable hypnotic and analgesic, especially advantageous in painful *cramps.* It has also been recommended for *whooping cough. Dose,* from one-half to one grain (0.032–0.065 Gm.).

Antithermin. *Phenylhydrazin-lævulinic acid.* $C_6H_5.N_2O = C(CH_3).C_3H_5O_2$.—This substance, which is obtained by the action of phenylhydrazin upon *acetopropionic acid,* occurs in colorless crystals, insoluble in cold water, soluble in ether and hot alcohol, melting point 108° C. (226° F.). It was first proposed in 1887 by Nicot as an antipyretic, and it has been especially experimented with by Drobner (*W. M. P.*, 1892, 540), who finds it active in *doses* of from eight to ten grains (0.5–0.65 Gm.). It produces, however, pallor, cephalic distress, excessive sweating, and other evidences of vasomotor depression, which require great caution in its use, and not more than three grains (0.2 Gm.) should be given.

Antithyroidin Moebius. *N. N. R.* 1917. *Serum Antithyroideum, Thyrodectomized Serum.*—This is the blood serum of sheep from which the thyroid gland has been removed, at least six weeks before the blood is drawn, preserved with 0.5 per cent. of phenol. It is an amber-colored fluid, with the faint odor and taste of phenol. It is marketed in vials containing two and a half drachms (10 mils). With proper precautions it is said to keep indefinitely. It is employed in the treatment of *exophthalmic goitre.* It is administered either hypodermically or by the mouth in *doses* beginning with eight to fifteen minims (0.5–1.0 mil) three times a day, gradually increasing the dose.

Antituman. *Sodium Chondritin Sulphate.*—Oestreich (*B. K. W.*, 1910) having observed that in carcinoma the arterial walls and cartilaginous tissues were not affected, believed that this immunity of these tissues was due to some substance found in them. On this theory he has employed *sodium chondritin sulphate* in the treatment of *cancers.* According to his observations, the remedy lessens suffering and improves the general health of patients who are suffering with inoperable cancers. Because of the pain which follows the injection of the remedy, it is marketed in combination with eucaine. The beginning *dose* is one and a half grains (0.1 Gm.) once or twice a day subcutaneously, which may be gradually increased.

Antitussin.—*Di-fluor-di-phenyl,* $(C_6H_4F)_2$, occurs as colorless crystals melting at 87° C. (189° F.). It forms the active ingredient of antitussin, which has been strongly recommended by Max Heim (*B. K. W.*, Dec., 1899) in the treatment of *whooping cough.* It is used as an ointment consisting of five parts of di-fluor-di-phenyl, ten parts of vaselin and eighty-five parts of lanolin. For a child a year old, about one-half drachm (2 Gm.) is slowly rubbed into the skin daily on the back, chest, and abdomen, about a drachm (3.9 Gm.) being used for a child five years old. (See also *Merck's Annual Reports,* 1905, 22 and 1907.)

Antodyne. *Anodyne.*—This is asserted to be *phenoxypropanediol,* a condensation product of phenol and *epichlorhydrine.* It has been brought forward as an analgesic in *neuralgia, gonorrheal arthritis* and other painful conditions. The *dose* is eight to fifteen grains (0.5–1 Gm.).

Anusol.—A proprietary suppository, alleged to contain a bismuth compound of *iodo-resorcin-sulphonic acid,* but it is apparently a mixture of zinc oxide, resorcinol, bismuth oxyiodide, balsam of Peru, and cacao butter. (*West. Drug.*, 1898, 75; *J. A. M. A.*, 1911, lvi, 441.) It is used in the treatment of *hemorrhoids.*

Aperitol.—Under this name is marketed a palatable form of *iso-valeryl-acetyl phenolphthalein* formed by the combination of esters of isovalerianic acid and acetic acids, in equal proportions.

This substance, which has been introduced as a cathartic, appears to be without any toxic action upon the system, for Hammer and Veith (*Med. Klin.*, 1908, iv) fed fifteen grains (1 Gm.) to a dog daily for ten days without any apparent effect. The same authors report a case in which a man took by mistake twenty-four grains (1.6 Gm.) without any more serious symptom than catharsis. Those who have employed the remedy are almost unanimous in the statement that it causes catharsis without (except in very occasional cases) any

griping. According to Miklos (*K. T. W.*, 1909, p. 747), in *chronic constipation* the remedy has the advantage that after two or three doses have been administered the regular evacuations will continue for several days even if the cathartic is withdrawn. The drug has been used not only in the treatment of chronic constipation, but also as a substitute for castor oil in the treatment of *enteritis*. The *dose* for an adult is ordinarily about three grains (0.2 Gm.).

Aphloia theæformis Benn. (Fam. *Bixaceæ*).—This plant is a native of Madagascar and is claimed to possess marked alterative properties and beneficial effects upon hemoglobin. It is administered as an infusion of the leaves, 30 Gm. of the plant being used to make 1 liter of infusion.

Aphthisin.—Under this name a mixture of 9 parts of potassium guaiacol sulphate and petrosulphol ammonium, 1 part, is exploited as a remedial agent in lung and bronchial diseases. Being an extremely hygroscopic substance it is best administered as a 6 per cent. syrup or in gelatin capsules combined with an oil. *Dose*, a teaspoonful of the 6 per cent. syrup several times daily.

Apinol. *N. N. R.*, 1917.—This is a product obtained in the destructive distillation of the wood of *Pinus palustris* Will. (*Pinus australis*). It is stated to consist mainly of *lævo-menthone*, $C_{10}H_{18}O$. It is a clear amber-colored oil, with a pine odor and having a sp. gr. of 0.946. It is used locally as an antiseptic and anesthetic application for *wounds*. It is also employed as an expectorant in chronic catarrhal conditions of the respiratory tract in *doses* of five to ten minims (0.3–0.6 mil).

Apocynum. *N. F. IV* (*U. S. P. VIII*). *Canadian Hemp. Black Indian Hemp. Dogsbane. Chanvre du Canada*, Fr. *Canadische Hanfwurzel*, G.—"The dried rhizome and roots of *Apocynum cannabinum* Linné (Fam. *Apocynaceæ*), without the presence of more than 5 per cent. of stems or other foreign matter." *N. F. IV.* Although latterly apocynum has fallen into disuse, some physicians have insisted that the *A. cannabinum* is a valuable remedy and that its unfavorable reputation has arisen from the use of other species. The drug of commerce in recent years has consisted of several species of Apocynum. A number of physicians in the United States have come to the conclusion that the absorption of Apocynum in the gastro-intestinal tract is uncertain and irregular, which led to its being deleted from the Pharmacopœia. It has been admitted into the N. F.

There are several indigenous species of this genus of very similar general aspect, the rhizome and roots of two of them being collected, viz.: *Apocynum cannabinum*, L., and *A. androsæmifolium*, L. Both plants abound in a milky juice, and have a tough, fibrous bark, which, by maceration, affords a substitute for hemp; hence the common name. It is used by the Indians of California for making all manner of cordage and for weaving.

In *A. cannabinum* the stems and branches are upright or ascending, terminated by erect and close, many-flowered cymes, which are usually shorter than the nearly sessile leaves, and the corolla has nearly erect lobes, with the tube not longer than the lanceolate divisions of the calyx. In *A. androsæmifolium* the branches are divergently forked, the leaves are slender petioled, the cymes loose and spreading, the open bell-shaped corolla with revolute lobes and a tube much longer than the ovate-pointed divisions of the calyx. *A. cannabinum*, of which there are a number of well recognized varieties, grows in gravelly or sandy soil mostly near streams, while *A. androsæmifolium* grows in dry thickets and open woods. According to E. A. Manheimer, the root of the latter is distinguished from *A. cannabinum* by the thick-walled stone cells, which are arranged in an interrupted circle near the middle of the bark. (*A. J. P.*, Nov., 1881. See also *A. J. P.*, 1888.) Holm has contributed an article on the structure of *A. cannabinum*. (*Merck's Rep.*, 1910, p. 277.)

It is described in the N. F. as: "Cylindrical, somewhat branched, of varying length, from 3 to 10 mm. in thickness; externally reddish-brown to grayish-brown, longitudinally wrinkled and occasionally with transverse fissures having vertical sides extending through the bark; fracture short; internally, bark light brown, from 1.5 to 3 mm. in thickness, wood faintly radiate and with large tracheæ, a small pith occurring in pieces of the rhizome. Almost inodorous; taste starchy, afterwards becoming bitter and somewhat acrid. Under the microscope sections of Apocynum show numerous laticiferous vessels in both the bark and pith. The stems of Apocynum have a comparatively thin fibrous bark, a light brown porous wood and a large, hollow pith. The powder is light brown, starch grains numerous, from 0.003 to 0.015 mm. in diameter, spherical, ellipsoidal, ovate, pyriform, or more or less irregular, sometimes more or less altered, swollen, and with a hyaline central cleft; numerous fragments of strongly lignified wood fibers, associated with tracheæ mostly having bordered pores, occasionally with spiral thickenings; fragments of cork layer few, the walls being of a reddish-brown color; an occasional fragment with laticiferous tissues; stone cells few or absent (*Apocynum androsaemifolium* Linné). Apocynum yields not more than 5 per cent. of ash." *N. F. IV.* The fresh root, when wounded, emits a milky juice, which concretes into a substance resembling caoutchouc. The stems of Apocynum have a comparatively thin, fibrous bark, a light brown porous wood and a large, hollow pith. In the dried state, the rhizome and roots are brittle and readily pulverized, affording a powder which is light brown, containing numerous starch grains which are from 0.003 to 0.015 mm. in diameter, spherical, ellipsoidal, ovate, pyriform, or more or less irregular, sometimes more or less altered, swollen, and with a hyaline central cleft. It also contains numerous fragments of strongly lignified wood fibers which are associated with tracheæ having bordered pores or occasionally with spiral thickenings, a few fragments of cork, the walls being of a reddish-brown color, and an occasional fragment with laticiferous tissues. Stone cells are not present in *A. cannabinum*, but are common in *A. androsæmifolium*.

The nature of the active principle of apocynum is as yet somewhat uncertain. Finnemore, in 1908, obtained from the *A. cannabinum* a crystalline substance to which the name of *cynotoxin* was applied. The following year Moore (*J. Chem. Soc.*, 1909, xcv) separated from the *A. androsæmifolium* a glucoside having the formula $C_{14}H_{16}O_8$, to which he applied the name of *apocynamarin*. These two principles which appear to be identical, possess the characteristic physiological effects of the crude drug. Taub and Fickewirth (*A. G. P.*, cliii, p. 239) believe that neither of these principles is chemically pure and that the activity of the plant

is due to an intensely bitter principle which is not of glucosidal nature and to which they apply the name of *cymarin.* This latter substance has been studied pharmacologically by Impens and has also been used practically by Allard (*D. M. W.*, 1913, xxxix, p. 783) and others, and appears to exert the characteristic effects of the drug. Cymarin is given in oral single *dose* of one two-hundredth of a grain (0.003 Gm.); daily *dose,* one-sixtieth to one-thirtieth of a grain (0.001–0.002 Gm.) intravenous or intramuscular *dose,* one one-hundred and twenty-eighth to one sixty-fourth of a grain (0.0005–0.001 Gm.).

Von Oefele (*Journ. Pharm. Elsass-Lothr.*, 1891, 325) described *apocynteine,* an alkaloid obtained from *A. venetum;* it is said to be a cardiac sedative.

Apocynum belongs physiologically to the digitalis group of cardiac tonics. Like digitalis it slows the pulse by stimulating cardiac inhibition, increases the vigor and tone of the heart muscle, and in overdose causes systolic spasm of the frog's heart, increases vasomotor tone and the activity of the kidney. It differs from digitalis only in the relative degree of its different effects. It appears to be the most powerful of the whole group in its effect upon inhibition, the slowing of the pulse being so extreme that despite marked constriction of the blood vessels the pressure is often lowered instead of elevated. According to Dale and Laidlaw (*Proceedings of the Royal Society of Medicine,* Dec., 1909), its action upon the vasomotor system is also relatively strong. It appears to be more irritant to mucous membranes than either digitalis or strophanthus, and therefore is prone to cause nausea and catharsis. Perhaps this local stimulant effect is also the explanation of its very powerful diuretic action, although Dale and Laidlaw believe that the effect upon the kidneys is due chiefly to a relative dilatation of the renal arteries.

Apocynum is useful in medicine as a diuretic and as a cardiac tonic. For the former purpose it is especially of service in *dropsies* due to heart failure, but has been also highly recommended in the *ascites* of *hepatic cirrhosis;* indeed, so powerful are its hydragogue properties that it has been dubbed the "vegetable trocar." As a tonic to the heart it is useful in the same classes of chronic *heart disease* in which digitalis is of service. The N. F., however, adds the following caution: "It has been stated that the absorption of Apocynum in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." Its irritant action upon the intestinal tract also militates strongly against its clinical usefulness; many patients are quite unable to take the drug because of the occurrence of emesis or purgation. *Dose,* five to fifteen grains (0.32–1.0 Gm.).

Aplopappus. *Aplopappus* (*Haplopappus*) *Baylahuen* Remy.—This composite herb is a native of Chili, where it is said to be relied upon as a stimulant in *flatulent dyspepsia* and *chronic inflammation* with *hemorrhage* of the lower bowels. It has been analyzed by H. H. Rusby (*A. J. P.*, 1890, 488), and later by H. Kahn (*A. J. P.*, 1891, 377). The former found a volatile oil, a fatty oil which had the specific odor of the plant, a brown acid resin of sharp taste, and tannin. The latter determined the percentage of volatile oil as 6.65, and of resin as 21.15. He also considers that this resin is a mixture of four different resins. G. Baille asserts (*B. G. T.*, Feb., 1889) that the remedy is valuable not only in *dysentery,* but in *genito-urinary catarrhs,* and also as a stimulating expectorant. *Dose,* one-half to one tablespoonful (7.5–15 mils) of a strong decoction, one part to five, may be given every two hours; or the fluid-extract, from five to twenty minims (0.3–1.3 mils). It has also been used in tincture form as an application to slowly healing *wounds* and *ulcers.*

Apocodeine Hydrochloride. $C_{18}H_{19}NO_2HCl$.—It is a greenish-yellow powder, soluble in water. Apocodeine has been investigated physiologically by W. E. Dixon (*B. M. J.*, 1902) who found that it lowered blood pressure by dilating the blood vessels, increased the intestinal peristalsis and produced a large secretion of saliva. Foy and Combemale (*R. T.*, 1907) have both employed it hypodermically as a laxative with pleasing results. Thirty minims (1.8 mils) of a 1 per cent. solution may be injected deeply into the muscles.

Apolysin. *Aconitylphenetidin. Monophenetidin Citrate.* $C_6H_4.OC_2H_5.NH(C_6H_7O_6)$.—A compound made by heating together citric acid and phenetidin with one molecule of water. It is a crystalline, yellowish-white powder of peculiar odor and taste. Its melting point is 72° C. (161.6° F.). It is soluble in cold water (1 in 25), alcohol, and glycerin, and in concentrated sulphuric acid without change of color. The solution in nitric acid turns a pale orange color. The aqueous solution is not clouded by silver nitrate, nor the acid solution by hydrogen sulphide. For tests of purity, see *Zeit. Oest. Apoth. Ver.*, 1910, 301. R. Seifert (*D. M. W.*, xxi, 1895) asserts that in *doses* of from eight to twenty-four grains (0.5–1.6 Gm.), three or four times a day, it is a valuable remedy as an antipyretic in various febrile diseases, and possessed of great power as an analgesic, similar in range of usefulness to acetphenetidin, but free from poisonous properties or disagreeable after effects.

Apomorphine-methylbromide. $C_{17}H_{17}NO_2CH_3Br$. *Apomorphine Bromomethylate. Euporphin.*—This occurs in colorless or yellowish crystals soluble in either water or alcohol. It is used as a nauseating expectorant in *acute bronchitis* and is asserted to have the advantage over apomorphine of being more stable and less liable to produce vomiting. The *dose* is from one-twentieth to one-twelfth of a grain (0.003–0.005 Gm.).

Aquilegia. *Aquilegia vulgaris,* L. *Columbine.*—A perennial herbaceous plant of the Fam. *Ranunculaceæ,* indigenous to Europe, but cultivated in our gardens. At one time considered diuretic and diaphoretic, columbine is not at present used in practical medicine. For further information concerning this drug, see *U. S. D.*, 19th ed., p. 1394.

Aralia. *N. F. IV. American Spikenard. Spignet.*—Aralia of the N. F. is "the dried rhizome and roots of *Aralia racemosa* Linné (Fam. *Araliaceæ*), without the presence of more than 5 per cent. of adhering stem bases, or other foreign matter. Rhizome of oblique growth, about 12 cm. in length and 5 cm. in thickness, somewhat flattened, tortuous, externally pale brown, somewhat annulately roughened, frequently cut longitudinally, whitish internally; nodes approximate, each with a prominent stem scar about 3 cm. in breadth; fracture fibrous; roots numerous, of varying length, from 5 to 25 mm. in thickness, usually cut longitudinally and furrowed, sometimes with transverse ridges and corky patches; light brown

or purplish-brown externally, whitish and spongy or porous internally; fracture of the cortex short, of the wood short and fibrous. Odor aromatic; taste mucilaginous, pungent and slightly acrid. A transverse section of the root shows a thick bark with several zones of secretion reservoirs containing oil, a well-developed cork with one or more hypodermal layers of lignified cells, and a more or less distinctly radiate wood. Examined microscopically, the powdered drug shows spherical or angular, single or two- or more compound starch grains, from 0.005 to 0.02 mm. in diameter, rosette aggregates of calcium oxalate from 0.03 to 0.07 mm. in diameter, tracheæ with scalariform or reticulate thickenings and simple or bordered pores, characteristic lignified cells from the hypodermis about 0.04 to 0.1 mm. in length and about one-half as broad, their walls showing simple pores (distinction from *Aralia nudicaulis*). Aralia yields not more than 10 per cent. of ash."

Aralia nudicaulis L. *False Sarsaparilla. Wild Sarsaparilla. Shotbush. Small Spikenard. Wild Licorice. Racine d'aralie nue, Petitnard,* Fr. *Nackte Aralienwurzel,* G.—This plant is an indigenous perennial. It grows from Canada to the Carolinas, inhabiting shady and rocky woods, being common in rich soil. The rhizome is horizontal, creeping, sometimes several feet in length, and 5 to 15 mm. in thickness, more or less twisted, of a yellowish-brown color externally, of a fragrant odor, and a warm, aromatic, sweetish taste. Alpers and Murray (*Proc. A. Ph. A.*, 1897, 182) found in it 3.05 per cent. of resin, 0.33 per cent. of oil, tannin, an acid, albumen, mucilage, and cellulose.

The roots of *Aralia racemosa* and *A. nudicaulis* have been used especially in domestic practice for their gently stimulant diaphoretic and alterative action, chiefly in *rheumatic, syphilitic,* and *cutaneous affections,* in the same manner and dose as genuine sarsaparilla. W. R. Monroe (*A. J. P.*, Oct., 1898) found in the rhizome of the *Aralia californica* S. Wats. a small amount of a pale yellow, very aromatic, volatile oil, but failed to detect saponin. Danzel found a glucoside *aralin* in the fresh leaves of *Aralia japonica.* (See *J. P. C.*, 1912, 530.)

Aralia spinosa, L. *Angelica-tree. Hercules club. Toothache-tree. Prickly Elder. Prickly Ash.*—The name "*prickly ash*" should be dropped, as it belongs properly to a species of *Xanthoxylum.* Angelica tree is an arborescent shrub which grows in Southeastern North America. The bark, root, and berries are used as alteratives.

Archidendron. *Archidendron Vaillantii.*—The bark and black beans of this leguminous plant of New South Wales are said to be an active paralyzant to the motor side of the spinal cord. (Bancroft, *Proc. Roy. Soc. N. S. W.*, 1886.)

Areca Nut. *Semen Arecæ. Betel Nut. Noix d'Areo,* Fr. *Arekanüse, Betelnüse,* G.—The *Areca Catechu,* L., is an East India palm. The fruit, which is ovoid and from 2 to 3 cm. in diameter, and of an orange-yellow color, contains the nut embedded in a fibrous, fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, the betel nut of commerce, is of a roundish-conical shape, rather larger than a chestnut, externally of a deep brown, diversified with a fawn color, so as to present a reticulate appearance, internally brownish-red with whitish veins, very hard, of a feeble odor when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin and various saline substances. It yields its astringency to water, and in some parts of Hindustan an extract is prepared from it having the appearance and properties of catechu. A red coloring matter known as *Areca red* is extracted, probably resulting from the decomposition of a tannin. It is insoluble in cold water and ether, soluble in boiling water and alkaline liquids, out of which it is precipitated by acids. E. Jahns (*Ber. d. Chem. Ges.*, 1888, 3404) has found three alkaloids in areca nut: 1. *Arecoline,* $C_8H_{13}NO_2$, identical with the *arekane* of Bombalon. 2. *Arecaine,* $C_7H_{11}NO_2 + H_2O$, which occurs in permanent, colorless crystals, soluble in water, insoluble in absolute alcohol, ether, chloroform, and benzene. 3. An alkaloid which exists in such small quantities that sufficient was not obtainable for close examination. On heating arecoline with strong hydrochloric acid to 150° C. (302° F.) it is decomposed into methyl chloride, CH_3Cl, and *arecaidine,* $C_7H_{11}NO_2$. This latter base forms colorless plates, stable in the air, fusing at from 223° to 224° C. (433.4°–435.2° F.), easily soluble in water, difficultly soluble in strong alcohol, and insoluble in ether and chloroform. Arecaidine has been shown to be *methyltetrahydronicotinic acid,* and has been made synthetically from nicotinic acid. The third alkaloid of Jahns is probably *guvacine,* $C_6H_9NO_2$, of which the methyl derivative is the base arecaidine before mentioned.

Immense quantities of areca nut are consumed in the East, mixed with the leaves of the Betel pepper (*Piper Betle,* L., *Chavica Betle* (L.) Miq.) and with lime, forming the masticatory so well known by the name of *Betel.* The red color which this mixture imparts to the saliva and the excrements is owing to the areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. (See *N. R.*, 1876, 71.) Arecoline resembles pilocarpine in its effects on the system. (Pätz, *Z. E. P. T.*, 1910, vii.) According to Jahns (*B. G. T.*, 1889) arecaine is the active principle of the areca nut, and a powerful tænicide, and is an active poison with an action of the type of muscarine and pilocarpine. Locally applied, or when given internally, it contracts the pupils.

Arecoline hydrobromide, $C_8H_{13}NO_2HBr$, a commercial salt, according to the experiments of Fröhner, is more powerful as a stimulant to the salivary glands than pilocarpine, and more active as a laxative than eserine. It is commended by veterinarians in the *colic* of horses, given subcutaneously in the *dose* of from one to one and one-half grains (0.065–0.096 Gm.). In human medicine it has been used in the dose of from one-fifteenth to one-tenth grain (0.004–0.006 Gm.) against the *tape worm* and as a myotic. A one-half to one per cent. solution produces a myosis, which reaches its maximum in about ten minutes and begins to subside in half an hour. It is claimed by various ophthalmologists that although in *glaucoma* its action is very transient, it produces a more considerable reduction of the intraocular pressure than can be obtained either with pilocarpine or eserine. It may cause considerable irritation but does not injure the continuity of the epithelium.

In India the areca nut has long been used as a vermifuge, the dose being a teaspoonful of the freshly grated nut, and its value against the *tape worm* has been confirmed by various European and American practitioners. The usual *dose* is from

one to two drachms (3.9–7.7 Gm.). In this country the nut has also been used for the making of a hard charcoal, employed as a basis of tooth-powder.

Argemone. *Argemone mexicana*, L. *Prickly Poppy. Argémone*, Fr. *Stachelmohn*, G.—An annual plant, belonging to the *Papaveraceæ*, growing in our Southern and Western States, Mexico, the West Indies, Brazil and in many parts of Africa and Southern Asia. For an illustrated paper on the structure of the seed of this plant by Schlotterbeck and Eckler, see *Proc. A. Ph. A.*, 1906, 467. The whole plant abounds in a milky, acrid juice, which becomes yellow on exposure, and has been used as a local application in obstinate *cutaneous diseases*, especially that affection known in Upper India as *dhad*, and also in cases of *warts* and even *chancres*. The alleged presence of morphine in *Argemone mexicana* has been disproven by J. O. Schlotterbeck (*Proc. A. Ph. A.*, 1901, p. 247), who finds that the plant contains *berberine*, besides an alkaloid, *protopine* (*argemonine* of Peckoldt). The seeds of the plant have been used in *colic*, 8 grains (0.5 Gm.), given in emulsion, and repeated if necessary every half hour until three doses have been taken. (*P. J.*, xiii, 642.) For further information concerning this drug, see *U. S. D.*, 19th ed., p. 1395.

Argulan.—This preparation is stated by Kolle and Rothermundt (*Med. Klin.*, 1913, p. 835) to be an antipyrine-sulphamino-mercury, and to represent 46.8 per cent. of mercury. It is used in the treatment of *syphilis* in *doses* of five one-hundredths to two-tenths gramme (1–3 gr.).

Arheol. *N. N. R.* 1917. *Santalol* (see also *Oleum Santali*, p. 789).—Arheol is an alcohol of the formula $C_{15}H_{26}O$, obtained from oil of sandal wood and constituting from 60 to 90 per cent. of the latter. It is an oily liquid, and is marketed in three grain (0.2 Gm.) capsules, six to twelve of which are given per day. It is affirmed to have the same remedial action as oil of sandal wood, but to be free from the tendency to cause gastric disturbance. *Dose*, five to ten minims (0.3–0.6 mil).

Arhovin. *N. N. R.* 1917. $C_{10}H_{13}C_6H_4(COOC_2H_5)(C_6H_5)_2NH$.—This is asserted to be a mixture of *diphenylamine, thymolbenzoate* and *ethylbenzoate* in molecular proportion. It occurs as a yellowish aromatic liquid with a mentholic taste, and is readily soluble in alcohol, and the fatty oils. It has been used as a urinary antiseptic in *cystitis* and *urethritis* and also as a local application in *vaginitis* and *endometritis*. According to Burchard and Schlockow (*Med. Woch.*, 1903), the ingestion of twelve 4-minim capsules over a period of three days imparted to the urine a marked antiseptic power. Although there have been a large number of favorable reports concerning this preparation, Deutsch (*W. K. W.*, 1906) and others have not had successful results from it. The *dose* for internal administration is from four to eight minims (0.25–0.5 mil) repeated several times a day. For local application a 5 per cent. solution in olive oil may be employed.

Aristochin. *N. N. R.* 1917. *Aristoquin. Aristoquinine. Diquinine carbonic ester.* $CO(C_{20}H_{23}N_2O_2)_2$.—A white or pinkish amorphous powder, soluble in alcohol, ether, chloroform, glycerin, and dilute acids, but insoluble in water. It is incompatible with alkalies and acids, being decomposed with the liberation of quinine. It is said to contain 96 per cent. of quinine, and probably is an effective antiperiodic, but has been chiefly used in *whooping cough*. It has the advantage over quinine of being practically tasteless. The *dose* for infants is about one grain (0.06 Gm.); for adults eight to fifteen grains (0.5–1.0 Gm.).

Aristolochia.—There are several species of the genus *Aristolochia* which are found in the herbalists' stores of India but do not enter commerce. Of these *A. bracteata* Retz is employed as an emmenagogue. Aristolochia of the Br. Add. was the dried stem and root of *Aristolochia indica* L. As sold in commerce this drug consists chiefly of stems with attached roots and is employed for the cure of *snake bite* and to produce abortion. The possession by it of any distinct medicinal properties is very doubtful. Later investigation has shown *A. rotunda* L. to contain *aristolochine*, $C_{32}H_{22}N_2O_{13}$, which has been used in Europe as a general tonic in febrile debility. The Br. Add. recognized the *concentrated liquor* (1 in 2 of 20 per cent. alcohol) (*Liquor Aristolochiæ Concentratus*, Br. Add.), *dose*, one-half to two fluidrachms (1.8–7.5 mils); the *tincture* (1 in 5 of 70 per cent. alcohol) (*Tinctura Aristolochiæ*, Br. Add.), *dose*, one-half to one fluidrachm (1.8–3.75 mils). Among the other species of *Aristolochia* which have been used medicinally *A. Clematitis* L., *A. longa* L., *A. rotunda* L., are still retained in official catalogues of the continent of Europe, where they are indigenous. *A. Pistolochia* L. of Southern Europe appears to have been the aristolochia of Pliny and is still used under the name of *Pistolochia*. The rhizome of *A. Clematitis* is very long, cylindrical, about 5 mm. in diameter, as a goose-quill or thicker, variously contorted, beset with the remains of the stems and roots, of a grayish-brown color, a strong, peculiar odor, and an acrid, bitter taste; that of *A. longa* L. is spindle-shaped, from 5 cm. to 3 dm. in length, about 2 cm. in thickness, fleshy, very brittle, grayish externally, brownish-yellow within, bitter, and of a strong, disagreeable odor when fresh; that of *A. rotunda* L. is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odor and taste; that of *A. Pistolochia* L. consists of numerous slender yellowish or brownish rootlets, attached to a common head, and possessed of an agreeable aromatic odor, with a taste bitter and somewhat acrid.

Many species of aristolochia, growing in the West Indies and Southern America, have been used medicinally. *A. cymbifera* Martius, known in Brazil as *milhommen, jarra, jarrinha*, and in Mexico as *guaco*, is said to have medicinal properties similar to those of the official species, but Butte affirms that it is depressant to the sensory nerve centers and is useful in *neuralgia* and *pruritus*. In the Argentine Republic the root of *A. argentina* is used as a diuretic and diaphoretic, especially in *rheumatism*. In the East Indies *A. indica* L. is employed for similar purposes with the European and American species, and the Arabians are said by Forskhal to use the leaves of *A. sempervirens* as a counter-poison. *A. fœtida* Kunth, of Mexico, or *Yerba del Indio*, is used as a local stimulant to foul ulcers. A number of species of aristolochia are employed as a remedy for *snake-bites* in various parts of the world, as *A. Serpentaria* L., in North America; *A. maxima* L. (the rhizome of which is called *Guaco* or *Contra Capitano*), in South America; *A. anguicida* L., in the Antilles; *A. brasiliensis* Mart. et Zucc.; *A. cymbifera* Mart. et Zucc.; *A. macroura* Gom.; *A. trilobata* L., etc. There is no sufficient reason for supposing that any one of them is effective.

Armeria. *Armeria vulgaris* Willd. (*Statice Armeria*, L.) *Maiden Pink.* (Fam. *Plumbaginaceæ*).—This plant, found in Europe, Asia, and Western North America, is said to be an active diuretic. (*Ph. Post*, May, 1890.)

Aromatic Wine. *Vinum Aromaticum. Vin aromatique*, Fr. *Aromatischewein*, G.—"Lavender, *one part* [or seventy-two grains]; Origanum, *one part* [or seventy-two grains]; Peppermint, *one part* [or seventy-two grains]; Rosemary, *one part* [or seventy-two grains]; Sage, *one part* [or seventy-two grains]; Wormwood, *one part* [or seventy-two grains]; Stronger White Wine, a *sufficient quantity*, to make *one hundred parts* [or one pint]. Mix the solid ingredients, and reduce them to a coarse (No. 20) powder. Moisten the powder with *four parts* [or six fluidrachms] of Stronger White Wine, pack it moderately in a conical glass percolator, and gradually pour enough Stronger White Wine upon it to make the filtered liquid weigh *one hundred parts* [or measure one pint]." *U. S.*, 1880.

This preparation of the U. S. Pharmacopœia of 1880 is practically identical with the *Vin aromatique* of the French Codex, which is made by macerating one hundred parts of aromatic species (a mixture of equal parts of the herbs used in our official aromatic wine, and in addition wild thyme and hyssop) with one hundred parts of *Teinture vulnéraire* (a tincture containing the same herbs, and ten more of similar properties) and one thousand parts of red wine. This wine is principally used as an astringent and stimulating lotion to *chancres, open buboes*, and other *indolent ulcers*. In many cases it should be diluted, but on occasion it may be employed of full strength. It is never given internally, and is rarely used in this country.

Arrow Poisons.—Up to the seventh century poisoned arrows were used in Europe in warfare, and they seem not to have disappeared from Spain until the sixteenth century, while poisoned daggers and poisoned swords were used even later for assassinations. The nature of the poisons employed is obscure, though it is stated that *Veratrum album*, L., and snake venom were used. The peregrinations of English and American travellers in Africa, and the various political changes and fomentations which have been the fruit of their discoveries—the war with Spain and the consequent bringing of attention to the Philippine Islands—have developed so much general interest in the wild natives of these various remote regions that we have thought it proper to prepare for our readers a general summary of what is known in regard to the poisons used by these various natives for the killing of game and the destruction of their enemies. In doing this we have thought that a geographical arrangement might well suffice. A number of arrow poisons in various parts of the world have been used to a greater or less extent as therapeutic agents, and are considered elsewhere in this work. Among these may be mentioned strophanthus, acocanthera, antiaris, and curare.

So far as our knowledge goes no poisonous arrows have ever been used in North America or in Northern Asia, unless, indeed, the statements made by Kracheninikow be correct. In the second volume of his *Voyage en Sibérie*, French edition, 1768, this traveller states that the roots of the plant known as *Zgate* are employed by several tribes living in the far north of Asia as an arrow poison, and it has been suggested, probably with insufficient reason, that the plant is an anemone. We have met with no recent author who has seen this poison.

The *Upas tieute*, which is used in the East Indies, is said to be obtained from a climbing woody plant growing exclusively in Java, the *Strychnos Tieute* of Leschenault. This author states that a decoction of the bark of the root is concentrated to the consistence of a thin syrup, then mixed with onions, garlic, pepper, etc., and allowed to stand until it becomes clear. The poisonous principles in both *Upas antiar* and *Upas ticute*, according to Pelletier and Caventou, is strychnine combined with igasuric acid. This poison produces death by violent convulsions, the heart stopping before respiration. (Hammond, *Am. J. M. S.*, 1860, p. 363.)

It is very probable that different extracts are employed by different tribes in the islands of the Malay Archipelago. Braidwood (*Ed. M. J.*, 1864) found the arrow poison known as *Dajaksh* to be a cardiac paralyzant. It is not clear whether this is the same as Borneo arrow poison examined by Leubuscher. (*Cb. I. M.*, Bd. xvii, 1896.)

The arrow poisons used by the natives of the Philippine Islands are, according to the researches of P. C. Plugge (*A. J. P.*, 1896, ii), obtained from the *Rabelaisia philippinensis* Planch. Plugge has found in it a non-nitrogenous glucoside, *rabelaisin*. This given in very large doses produced in animals some convulsive movements, followed by profound muscular relaxation, loss of reflexes, and general paralysis, ending in death from asphyxia. On the heart it acted as an energetic stimulant, belonging to the digitalin group. (See also I. Rosenthal, *Sitzungsb. f. Physk. u. Med. Soc.*, Erlangen, 1894.)

An arrow poison is used by the Malays, under the name of *Ipoh;* it is said to be obtained from *Derris* (*Pterocarpus*) *elliptica* (Fam. *Leguminosæ*), or the *tuba root*, which is much used in Java as a fish poison. It contains an active acid resin, to which the name of *derrid* has been given. Derrid appears to be one of the most powerful fish poisons known, as one five-millionth part stupefied gold fish in a few moments, and killed them within half an hour. (*P. J.*, 1890, xxi.) According to the researches of van Hasselt (*A. I. P. T.*, 1911, xxi, p. 242), closely allied, physiologically, to derrid are *pachyrhizid*, from the *Pachyrhizis angulatis*, and *nicoulin*, from the *nekoe* or *stink-wood*. These drugs are powerful poisons to the central nervous system, especially the respiratory center, and in larger doses cause slowing of the pulse by a direct action upon the heart muscle.

The natives of Perak, in the Straits Settlements, use an arrow poison stated to be a combination of aqueous extracts from the root bark of three trees, the individual extracts being known as *ipoh aker, aker lampong*, and *prual*. Ipoh aker and aker lampong are believed to be obtained from undescribed species of Strychnos; extracts were prepared from the root bark of these trees by Ralph Stockman (*Lab. Rep. Roy. Soc. Edinburgh*, vol. vi, 1897), and found to be of similar physiological power, each of them having a digitalis-like action and also a well marked curare-like action, causing arrest of the heart in systole and loss of power in the motor nerve endings. *Prual* is said to be made from the root bark of *Coptosapelta flavescens* Korth., now recognized as *C. macrophylla* (Roxb.) K. Sch. (Fam. *Rubiaceæ*); in the experiments of Stockman it was found to be a violent poison, very

rapidly killing the muscle at the point of inoculation, and soon involving in a fatal influence the whole muscular system, so that the animal after a large dose collapsed almost at once with diastolic cardiac arrest.

The *African arrow poisons* are quite numerous. *Exuja* or *Echugin* is a blackish-brown, crumbly, odorless, and intensely bitter arrow poison, used by the Ovambos of Southwest Africa. It is said to be yielded by an apocynaceous shrub, *Idaneum* (*Adenium*) *Boehmianum*. From it R. Böhm (*Cb. M. W.*, 1889) isolated the crystalline glucoside ($C_5H_8O_2$), *echugin*, and a resinous body, *echugon*. The glucoside crystallizes in small, colorless, satiny, rhombic plates, easily soluble in water and alcohol, and insoluble in ether. It is present to about 10 per cent. in the crude substance, and is said to very closely resemble strophanthin in its physiological properties.

The arrow poison used by the pygmies of Central Africa has been obtained by Surgeon Parke, and is described in the *P. J.*, April, 1891. It has been found to contain two active alkaloids, *erythrophlœine* and *strychnine*.

The Sakayes, the Somangs, and the Wa Kamba tribes in Eastern Africa produce arrow poisons whose relations with one another are still obscure. *Hippo*, according to Laborde, causes in the lower animals vomiting, followed by tetanic convulsions and an almost simultaneous arrest of the respiration and cardiac action. (*P. J.*, July, 1887.) *Vakamba* of Laborde (*Ibid.*) is probably the same as the *ukambin* which has been studied by H. Paschkis, who found its active principle to be a crystalline body belonging to the digitalis group, and causing in the lower animals elevated blood pressure, fibrillary contractions of the muscles, and systolic arrest of the heart. (*Cb. M. W.*, 1862.)

An exceedingly bitter arrow poison, used by the tribes who inhabit the country of Segon in the French Soudan, has been examined by Ferré and Busquet (*A. de P.*, 1895, vii), who find that its active principle is a crystalline glucoside which is a very powerful muscle poison, affecting directly the heart, and producing very rapidly general paralysis, with salivation, exophthalmia, disturbance of respiration and circulation. The first influence is to increase greatly the arterial pressure. The whole action of the poison is very similar to that of strophanthin. For an investigation of South African plants by Juritz, see *P. J.*, 1906, 87.

The Australian natives, according to Lewin, (*A. E. P. P.*, 1912, lxviii, p. 333), derive an arrow poison from the *Buphane disticha* Herb. (*Hœmanthus toxicarius* L.). He found in this an alkaloid to which he gave the name of *hœmanthine*. It somewhat resembled scopolamine in its action, being both a narcotic and mydriatic, and may be the same as that described by Tutin (*Tr. Chem. Soc.*, 1911, xcix) under the name of *buphanine*. Tutin also found several other alkaloids, one of which was identified as *narcissine*.

Animal Poisons.—The use of animal arrow poisons is uncommon, though the Choco Indians, in Colombia, South America, are said to prepare a very deadly extract by holding a tree-frog, the *Hyla choccensis*, on a stick near a fire, and scraping off the subsequent exudate from the skin. As it is asserted that an exudate can be obtained from the skin of the ordinary European toad which is a violent heart poison, the extract employed by the Choco Indians is probably a cardiac paralyzant. Again, according to Livingstone, confirmed by Baines, some of the Bushmen prepare a poison from a cream-colored grub or caterpillar, which they term *'Nga*, said to be the first stage of the beetle *Diamphidia locusta*. The grub is gradually squeezed between the forefinger and thumb, and the colorless exudate smeared over the arrowhead. Boehm and his pupil Starcke have found this poison to be similar in its action to the snake poisons, to be dependent for its activity upon a toxic albumose, and to be non-toxic when given by the mouth. As previously stated, it is also probable that snake venom is sometimes mixed with the various vegetable poisons used by barbarians.

Natives along the Amazon River obtain an arrow poison from the venom of a toad, the *Bufo agua*. This has been examined by Abel and Macht (*J. P. Ex. T.*, 1912, iii, p. 319) who found in it 5 per cent. of epinephrine, and a neutral principle to which they gave the name *bufagin*, and assigned the formula of $C_9H_{12}O_2$. It exercises a powerful digitalis-like effect, the fatal dose for the dog being seven-tenths of a milligramme per kilo.

Arsacetin. *N. N. R.* 1917.—Arsacetin is *Sodium Acetyl Arsanilate*, $C_6H_4(NH.CH_3CO)(AsO.OH.ONa) + 4H_2O$, a compound derived from sodium arsanilate by replacing a hydrogen atom of the amino group in sodium arsanilate, with an acetyl radical. It is a white, crystalline substance, odorless and tasteless, soluble to the extent of 10 per cent. in cold and 30 per cent. in warm water. It is free from arsenous or arsenic acid, and solutions are not affected by boiling. An hour's heating in the autoclave has no action on it. One part of arsacetin in ten of water and a few drops of silver nitrate solution added will produce a pure white precipitate. Its solution, clear and colorless, should show at most a faint acid reaction. Its capability of standing thorough sterilization gives it the advantage over compounds of the same nature—like sodium arsanilate, etc.

It has been used for the treatment of *syphilis*, and although some authors have reported favorably, the trend of opinion seems to be that it is inferior, in curative value, to mercury, and that there is danger of producing optic atrophy as is seen after atoxyl. It has also been used in the treatment of *trypanosomiasis* with more or less success, but is less efficient than atoxyl. Arsacetin has been used mostly in *doses* ranging from one-half up to one and a half grains (0.03–0.1 Gm.), although some authors have employed much larger quantities.

Arsenic Alginate.—This is the combination product of sodium alginate and arsenic chloride. It is a white powder, soluble in alkaline solutions. It is decomposed in the intestinal tract after passing through the stomach unaltered.

Arsenoferratin. *N. N. R.* 1917. (*Sodii arsenoferri albuminas.*)—This is an organic compound of albumen and arsenic with ferratin. A solution of a similar composition is on the market under the name of *arsenferratose*. The latter is a brownish liquid, contains 0.3 per cent. of iron and 0.003 per cent. of arsenic. The solid form of arsenoferratin is marketed in tablets of four grains (0.25 Gm.). They are used in the treatment of *anemias*. Of the solid form 3 to 6 tablets, each containing four grains (0.25 Gm.), may be given in twenty-four hours. Of the liquid arsenferratose the *dose* is one to two teaspoonfuls three times a day.

Arsenogen.—This preparation is a combination of iron, phosphorus and arsenic, with paranu-

cleinic acid. It is a yellowish powder and is used in the treatment of *anemia* and similar disorders.

Arsenophenyl Glycin.—This combination has been employed especially in the treatment of *sleeping sickness.* Zupitza and Raben (*B. K. W.*, 1910) report favorably upon it, but Scherschmidt (*D. M. W.*, 1911) finds it inferior to atoxyl; it appears to be equally dangerous. The *dose* is from eight to fifteen grains (0.5–1 Gm.) daily, for two or three consecutive days, by intramuscular injection.

Arsentriferrin is a tasteless, orange-colored powder furnished in tablets each containing five grains (0.32 Gm.). The *dose* is one tablet given in anemic conditions.

Arsentriferrol. *Elixir Arsen-triferrini.*—This is an elixir of arsentriferrin, containing in each fluidrachm (4 mils), about one grain (0.06 Gm.) or arsentriferrin. It is said to be useful in *anemia.* (See *Merck's Annual Report*, 1913.)

Arsoferrin.—This is said to be an organic combination containing iron, arsenic and glycerophosphoric acid. It is dispensed in the form of tablets and each tablet corresponds to one-third grain of iron oxide and one one-hundred and twelfth grain of arsenous acid. According to Gordon (*Med. Klin.*, 1909), this is a valuable remedy in the treatment of various forms of *anemia* and *debility* in which iron and arsenic would be indicated. The beginning *dose* is one tablet three times a day, which may be gradually increased up to three or four tablets three times a day.

Arsol.—This is a compound consisting of phosphorus and calcium arsenate. It is used as a nerve tonic.

Arsylin. *Arsen-protylin.*—This is an arsenic and phosphorus compound containing these two elements in combination with egg albumen. It is a yellowish-white, odorless powder insoluble in water, with a slightly acid taste. It is administered in *doses* of fifteen grains (1 Gm.) (equivalent to $^1/_{60}$ grain of arsenic).

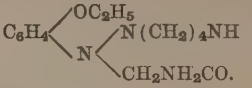
Artabotrys. *Artabotrys odoratissima* (Roxb.), R. Br. (Fam. *Anonaceæ*) and *Anona uncinata* Blanco. *Ilag-ilag de China*, Sp.-Fil. *Alag-ilag Sonson*, Tag.—A decoction of the leaves of these plants is used in the Philippine Islands in the treatment of *cholera;* the overdose is said to be capable of producing abortion.

Artar Root.—This is a drug coming from the west coast of Africa, possibly the product of *Fagara Xanthoxyloides* Lam. (Fam. *Rutaceæ*), the leaves of which have been found in commercial specimens. Two alkaloids have been discovered in it by Giacosa and Nionari, one of which is said to resemble somewhat in its action veratrine, but to be a stimulant to the heart. (*Ph. Centralh.*, 1887, No. xxv.)

Artemisia frigida Willd. *Sierra Salvia. Colorado Mountain Sage.* (Fam. *Compositæ.*)—This Rocky Mountain plant, which is found growing in immense quantities from the Saskatchewan to Western Texas, and westward, is said to be much used in that region as a diaphoretic, antiperiodic, and mild cathartic. F. A. Weiss (*A. J. P.*, 1890) found indications of a glucoside. One or two drachms (3.9 or 7.7 Gm.) of the powdered leaves, or one or two fluidrachms (3.75 or 7.5 mils) of the *fluidextract*, may be administered in hot infusion every half hour until perspiration has set in. The *Artemisia nana*, one of the North American sage brushes, is reported to yield a volatile oil, which is rich in camphor. (*P. J.*, 1910, xxxiv, 237.)

Arterenol.—*Aminoäthanolpyrocatechin* is a reduction product of aminoacetopyrocatechin. Its hydrochloride, $(OH)_2.C_6H_3.CHOH.CH_2.NH_2.HCl$, is crystalline and slightly soluble in water. Its therapeutic uses are analogous to those of epinephrine. It is incompatible with alkalies and with ferric chloride and should be kept away from light.

Arthritiicin.—A synthetic product used in the treatment of *gout* is a combination of diethylenamine and the nitrile of the ethyl kresol of amido acetic acid.



Arum.—The root or corm of *Arum maculatum* L. (Fam. *Araceæ*), is occasionally used as a medicine in Europe. Its properties closely resemble those of *Arisæma triphyllum.* Its constituents, according to Enz, are a neutral acrid volatile principle soluble in ether, starch, gum, mucilage, sugar, lignin, albumen, saponin, fixed oil, resin, and calcium phosphate, the fresh corm containing 58.4 per cent. of water, 5.2 of lignin, and 27.2 of starch. (*A. J. P.*, xxxi.)

Arisæma triphyllum (L.) Schott. *Gouet à trois feuilles*, Fr. *Dreiblättriger Aron*, G. (Fam. *Araceæ.*) *Dragon-root, Pepper Turnip, Indian Turnip, Jack-in-the-pulpit, Wake-robin.*—This plant is common in all parts of the United States, growing in moist shady places. The corm was formerly official. It is roundish, flattened, an inch or two in diameter, covered with a brown, loose, wrinkled epidermis, and internally white, fleshy, and solid. In the recent state it has a peculiar odor, and is violently acrid. It was found by D. S. Jones to contain, besides the acrid principle and from 10 to 17 per cent. of starch, albumen, gum, sugar, extractive, lignin, and salts of potassium and calcium. (*A. J. P.*, xv, 83.) The acridity has been ascribed to the raphides of calcium oxalate by R. A. Weber (*J. Am. C. S.*, 1891, p. 215). This has been denied, Schneegans proving that *A. maculatum* contains saponin and Spica and Biscaro ascribe the acridity to the same principle. (*Ph. Centralh.*, 1895, p. 731.) The Indian turnip may be preserved fresh for a year, if buried in sand.

From both *Arum maculatum*, L., and *Arum italicum*, Mill., Herbert and Heim (*P. J.*, July 31, 1897) separated a saponin, also a brownish, oily, liquid alkaloid closely resembling coniine in its properties, but less active. They also found a saponin in the arum tubers.

Both the European and American arum are, in their fresh state, violent irritants to the mucous membranes, producing when chewed insupportable burning in the mouth and throat. Taken internally, this plant causes violent gastro-enteritis, which may end in death. The fresh, partially dried root has been used internally as a stimulant to the secretions, especially in *asthma, whooping cough, chronic catarrh,* and *rheumatism. Dose,* ten grains (0.65 Gm.), two or three times a day, increased to half a drachm (2 Gm.). The perfectly fresh root should not be used, and the fully dried root is inactive.

The corm of the European arum contains much starch, and a farina is prepared from it, in small quantities, in the Isle of Portland, on the south coast of England, and called *Portland arrow root,* or *Portland sago.* The root of *A. esculentum*, L. (more correctly *Colocasia antiquorum* Schott.), which abounds in starch, is much used by the

natives of the Hawaiian and other islands of the Pacific as an article of food, having been previously deprived of its acridity by heat.

Asarabacca.—*Asarum europæum* L., is an acrid, herbaceous perennial plant, of the Fam. *Aristolochiaceæ*, growing in woods and shady places in Europe, Siberia and the Caucasus. The rhizome is from 2 to 3 inches in thickness, of a grayish color, quadrangular, knotted and twisted, and sometimes furnished with rootlets at each joint. It has an odor similar to that of pepper, and acrid taste, and affords a grayish powder. The leaves, which have long petioles, are kidney-shaped, entire, somewhat hairy, of a shining deep green color when fresh, nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. According to Feneulle and Lassaigne, the *root* contains a concrete volatile oil (see *Asarum*), a very acrid fixed oil, a yellow substance analogous to *cystin*, starch, albumen, mucilage, citric acid, and saline matters. The root and leaves of asarabacca are powerfully emetic and cathartic, in *doses* of from thirty grains to a drachm (2.0–3.9 Gm.), but are used almost exclusively as an errhine in *headache*, and *rheumatic affections* of the face, mouth, and throat. One or two grains (0.065–0.13 Gm.), snuffed up the nostrils, produce much irritation, and a copious, persistent flow of mucus. For further information concerning this drug, see *U. S. D.*, 19th ed., p. 1400.

Asarum. *N. F. IV. Wild Ginger, Canada Snake-root. Asaret du Canada*, Fr. *Canadische Haselwurzel*, G.—"The dried rhizome and roots of *Asarum canadense* Linné (Fam. *Aristolochiaceæ*), with only an occasional leaf or flower present, and without the presence of more than 5 per cent. of other foreign matter." *N. F.* The plant has in all its parts an aromatic odor and an aromatic, slightly bitter taste, which it imparts to alcohol and hot water. "Of horizontal growth, occasionally branched, two-edged when young, quadrangular when older, finely striate, usually more or less twisted, from 5 to 17 cm. in length and from 2 to 4 mm. in thickness; nodes enlarged with irregular scars from petioles and remains of pedicels; internodes with annular scars from scales; dark purplish-brown externally; fracture short, internally whitish, starchy or resinous; attached roots few, from 5 to 7 cm. in length and not over 1 mm. in thickness, having from four to six radial fibro-vascular bundles. Odor aromatic, non-irritating upon heating; taste pungent and slightly bitter. In transverse section the rhizome shows a thick bark with numerous oil cells, a wood with about twelve fibro-vascular bundles and a large pith. Examined microscopically, the powdered drug shows simple and two- to four-compound starch grains, the individual grains being from 0.004 to 0.02 mm. in diameter, and tracheæ with scalariform or reticulate thickenings, a few spiral. Asarum yields not more than 12 per cent. of ash." *N. F.* The chief constituent is the volatile oil, at one time largely used in perfumery. According to Petersen, the oils of *Asarum Europæum* and *Asarum canadense* are composed in the main of one compound, which is identical with the *methyl ether of eugenol*, $C_6H_3(OCH_3)_2.C_3H_5$, a compound which has been made synthetically but not previously found in nature. Under the trade name *Asaron* a camphor derivative of *Asarum Europæum* is recommended as an antiseptic and tonic. It is given the formula $(CH_3)_3.C_6H_2(CH)_2CH_2CH_3$, and occurs as a whitish-yellow crystalline powder or fragments possessing a faint biting taste. According to the researches of Power and Lees (*Trans. Chem. Soc.*, 1902) the oil of *Asarum canadense* contains the following substances: a phenol, $C_9H_{12}O_2$; pinene, apparently a mixture of the d- and l- forms; d-linalool, l-borneol, l-terpineol, geraniol, eugenol-methyl-ether, a blue oil, of undetermined composition, consisting of oxygenated substances of alcoholic nature; a lactone, $C_{14}H_{20}O_2$, palmitic acid, acetic acid, and a mixture of fatty acids intermediate between acetic and palmitic acids. For formulas for fluidextract, syrup, and oleoresin, see *A. J. P.*, 1876, 155. F. P. Streeper (*A. J. P.*, 1888, 6) proved that strong alcohol was the proper menstruum for the fluidextract. The medicinal properties of this drug are those of a feeble aromatic. From a half to one drachm (2–3.9 Gm.) may be used. It is employed as an aromatic adjuvant to tonic mixtures and infusions. From *Asarum arifolium* Michx., E. R. Miller obtained from 7 to 10 per cent. of volatile oil having a sassafras odor, sp. gr. 1.0585 (*P. J.*, lxix); see also *Schim. Rep.*, 1902, p. 12; also *Proc. Alabama Pharm. Assoc.*, 1910, 56–58.

Asbestos.—This term is applied to several mineral substances which occur in long capillary crystals placed side by side, the whole producing a fibrous mass which possesses qualities that render asbestos very valuable in the arts. Asbestos is incombustible, insoluble, and a poor conductor of heat. It is either *hydrated magnesium silicate*, when it is known as *chrysotile*, or a compound of silicon, lime, and magnesium known as *amphibole* asbestos (for analysis, see *P. J.*, 1901, p. 575), and is found in Italy, in the Tyrol, Corsica, Savoy, in the Pyrenees, in Cornwall, Scotland, and elsewhere in Europe. It is largely mined in Canada, the production in 1915 having been 113,115 tons, valued at $3,491,450. For its general properties and uses, see *Ph. Rec.*, 1885, 232. In the laboratory it is used for filtering purposes, for which it is admirably adapted. It is also used as a non-conductor of heat in connection with various forms of apparatus. (See *A. J. P.*, 1883, 37; *Ph. Rund.*, 1885, 252.)

Asbolin.—Under this name Braconnot has introduced a brownish-yellow syrupy liquid, prepared from an aqueous infusion of lamp black. Béhal and Desvignes state that it consists mainly of pyrocatechin and homopyrocatechin. It has been used in the treatment of *tuberculosis*.

Asclepias. *N. F. IV. Butterfly weed. Pleurisy root.*—This is described in the N. F. as "the dried roots of *Asclepias tuberosa* Linné (Fam. *Asclepiadaceæ*), without the presence of more than 5 per cent. of foreign matter. Usually cut or broken pieces, of variable size, of an irregularly fusiform root, which, when entire is from 10 to 20 cm. in length and from 0.5 to 5 cm. in thickness; occasionally branched; externally pale orange-brown, becoming grayish-brown, annulate above, the surface roughened by numerous fine intersecting grooves; bark thin; fracture tough, the broken surface granular and white, with inconspicuous pale yellow wood bundles and large white medullary rays. Odor slight; taste bitterish and disagreeable, somewhat acrid. The powdered drug is yellowish-brown and, when examined with the microscope, shows numerous simple or two- to four-compound starch grains, the individual grains up to 0.015 mm. in diameter, somewhat spherical in shape, or truncate and often with a sleft at center; calcium oxalate crystals in rosette aggregates up to 0.04 mm. in diameter; strongly lignified thick-walled stone cells up to 0.075 mm.

in diameter and with simple or branching pores; tracheæ with reticulate markings, occasionally bordered pores; spindle-shaped sclerenchyma fibers few, lignified and mostly with simple pores. Asclepias yields not more than 9 per cent. of ash." *N. F.* It grows from Ontario to Minnesota, most abundantly southward and southwestward. It contains a glucosidal principle, *Asclepiadin*, which occurs as an amorphous body, is soluble in ether, alcohol and hot water. It also contains several resins and a trace of volatile oil. Besides the American species *Asclepias tuberosa*, *A. syriaca*, and *A. incarnata*, which were formerly recognized by the U. S. Pharmacopœia, various other species of the genus have been used medicinally.

To the root of the *A. tuberosa* have been ascribed diaphoretic, expectorant, and cathartic properties. In the Southern United States the drug has been given in *pulmonic catarrhs* in *doses* of from twenty grains to a drachm (1.3–3.9 Gm.) in a powder or in the form of a decoction; as a diaphoretic, a teacupful of the decoction (1 in 30) every hour until some effect is produced. For additional information concerning Asclepias species, see *U. S. D.*, 19th ed., p. 1400.

Aseptol. *Sozolic Acid. Orthophenol-sulphonic Acid.* $C_6H_4(OH)SO_3H[1.2]$.—A clear yellow to a yellowish-brown solution with a phenol-like odor. The marketed solution contains 33⅓ per cent. of the acid. It is very soluble in water, alcohol, etc., and is used as a disinfectant after the manner of phenol; claimed to be less toxic than phenol and more antiseptic.

Aseptolin. *Pilocarpinphenol. Pilocarpin carbolate.* $C_{11}H_{16}N_2O_2OH.C_6H_5$.—It is an oily fluid, soluble in both water and alcohol, and is used in a .02 per cent. aqueous solution with 2.75 per cent. solution of phenol added in the treatment of *malaria* and *tuberculosis*. Of this solution 4 mils is injected once daily or in 8 separate *doses* of 0.5 mil each.

Asferryl.—Asferryl is asserted to be a combination of an iron salt and arsenio-tartaric acid. It is a greenish-yellow powder, sparingly soluble in water and acids, readily soluble in dilute alkalies. It contains 18 per cent. of iron and 23 per cent. of arsenic. According to Bachem (*Ther. Rund.*, 1908), asferryl is thirty-five times less toxic than arsenous acid. Fries (*Ther. Geg.*, 1909), found that small doses were well tolerated by the stomach, but that larger quantities gave rise to loss of appetite, gastric pain and even vomiting. He used it with satisfactory results in various types of *anemia*. It is marketed in tablets containing two-thirds of a grain (0.04 Gm.) each. One-half to one tablet may be given two or three times a day.

Asimina. *Asimina triloba* (L.) Dunal. (Fam. *Anonaceæ.*)—J. U. and C. G. Lloyd have found in the common *pawpaw* an alkaloid, *asiminine*, besides a volatile oil. (*A. J. P.*, 1886.) T. M. Fletcher failed to find an alkaloid, but gives the principal constituents as fixed oil, 3.53 per cent.; resin, 343 per cent.; resin insoluble in ether, 9.5 per cent.; glucose and extractive, 8 per cent. (*A. J. P.*, 1891, 476.)

Asparagus. *Asparagus officinalis*, L. *Asperge*, Fr. *Spargel*, G. *Esparaguera*, Sp. (Fam. *Convallariaceæ.*)—This well-known garden vegetable is a native of Europe. It is perennial and herbaceous. The *root*, which is inodorous, and of a weak, sweetish taste, is used in France as a diuretic and aperient in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. In the *berries* H. Reinsch has found a large proportion of glucose and a yellowish-red coloring matter, *spargin*. (*A. J. P.*, xlii, 371.) From the juice of the young shoots Robiquet and Vauquelin obtained a peculiar crystallizable principle, called *asparagin*, $C_4H_8N_2O_3$, which has since been found in a number of plants. (See *Althæa*, p. 120.)

There is at present no sufficient reason for believing that asparagus is of value in practical medicine. The peculiar heavy odor which it imparts to the urine has been the chief foundation for the belief in its diuretic properties; but Nencki (*Provincial Med. Journ.*, March, 1891) appears to have demonstrated that this odor is due to the presence in the urine of *methyl-mercaptan*, a gas which is frequently produced in minute quantities in the intestines by the decomposition of proteids. According to Justin D. Lyle (*N. Y. M. J.*, July, 1892), eating asparagus causes the urine to answer Trommer's, Fehling's, and Böttger's glycosuria tests, although sugar is not present. Tanret found two carbohydrates, *asparagose* and *pseudo-asparagose*, in the roots and green berries of asparagus. (*P. J. Tr.*, 1909, 205.) Certain physiologists have claimed that asparagin has an effect on metabolism, but this view is probably incorrect. (See *Z. B.*, 1892, x.) Asparagus may be administered internally in the form of the syrup produced from the fresh juice or from the tincture. For further information concerning Asparagus, see *U. S. D.*, 19th ed., p. 1401–1402.

Aspirophen. *Phenocoll Acetylsalicylate.*—Under this name has been introduced a mixture of thirty-seven parts of free salicylic acid with sixty-three parts monoacetylphenocoll. It is employed as an analgesic and antirheumatic. Fackelmann (*Th. M.*, July, 1907) asserts that it is less prone to produce cinchonism than other salicylates and is more potent in controlling pain and less likely to produce sweating than aspirin. The *dose* is from eight to fifteen grains (0.5–1 Gm.).

Asplenium. *Asplenium Filix-fœmina* (L.) Bern. *Female Fern.*—The rhizome of the female fern has been supposed to possess similar vermifuge properties to that of the male fern. At present, however, it is not used. The vulgar name of *female fern* is also given to the *Pteris aquilina*, or *common brake*, which is further said by some authors to have the property of destroying the *tape worm*. The leaves of two species of *Asplenium*, *A. Trichomanes*, L., or *common spleenwort*, and *A. Adiantum-nigrum*, L., or *black spleenwort*, are mucilaginous, and have been used as substitutes for *maidenhair* (*Adiantum Capillus-Veneris* L., and *A. pedatum* L.) as pectorals, though destitute of their aromatic flavor.

Aster. *Aster punicеus*, L. (Fam. *Compositæ.*)—The aromatic astringent rootlets of this indigenous plant have been employed as a stimulating diaphoretic in *rheumatic* and *catarrhal affections*.

Asteracantha. *Asteracantha longifolia* Nees. *Ik Kirit.* (Fam. *Acanthaceæ.*)—This Indian plant is said by A. Jayesingba to be an energetic hydragogue diuretic. (*Ph. Z. R.*, Sept., 1887.)

Asterol. *Mercury paraphenolsulphonate with ammonium tartrate.* $C_{12}H_{10}O_8S_2Hg.4(C_4H_4O_6[NH_4]_2) + 8H_2O$.—A micro-crystalline reddish-white powder soluble in warm water. This substance was brought forward as a local disinfectant by Steinmann (*B. K. W.*, 1899, p. 229) with the claims that it is as active as corrosive sublimate

in its antiseptic powers without having local corrosive properties, and also not losing its bactericidal action in albuminous media. Vertun (*B. K. W.*, 1899, No. 20), however, finds that these assertions are not warranted. It has also been employed by intramuscular injection in the treatment of *syphilis*. *Dose*, one-half to three grains (0.03–0.2 Gm.).

Astrolin. *Methyl-ethyl-glycolic antipyrin.* $C_5H_{10}O_3.C_{11}H_{12}ON_2$.—This is a colorless, crystalline powder, with pleasantly acidulous and faintly bitter taste, soluble in water or alcohol. It melts at 64°–65° C. (147.2°–149° F.) and represents 61.5 per cent. of antipyrin, for which drug it is proposed as a substitute: Winzheimer finds it without deleterious influence upon the lower animals. It is suggested for the treatment of *neuralgic headaches* in *doses* of fifteen grains (1 Gm.).

Asurol.—This is asserted to be a double salt of mercuric salicylate and amido-oxy-isobutyric sodium, containing 40.3 per cent. of mercury. It is readily soluble in water. This preparation has been recommended for the hypodermic injection of mercury, especially in the treatment of *syphilis*. According to Neisser (*Th. M.*, 1909, p. 627), however, while it is rapid in its effects, it is not of itself sufficient for the cure of syphilis and should therefore be used in conjunction with some other form of mercurial treatment. The solutions should always be made with boiled distilled water, as the drug is incompatible with both carbonic acid and sodium chloride. It should be freshly prepared because on long standing a turbidity occurs, probably through the action of the carbonic acid of the air. The beginning *dose* is sixteen minims (1 mil) of a 5 per cent. solution, which would represent one-third of a grain (0.02 Gm.) of mercury.

Atherosperma. *Atherosperma moschatum* Labill. *Australian Sassafras.* (Fam. *Monimiaceæ.*)—The bark of this tree, a native of Southern Australia, is said to have been long used by the aborigines, and later by the settlers, in *rheumatism* and in secondary *syphilis*, and has been highly commended by Greeves (*L. L.*, 1862) in acute *bronchitis*. It has been stated that both the bark and the volatile oil are powerful poisons, and Zeyer (*Vierteljahrschr. f. Pract. Pharm.*, x, 504) obtained from the drug an alkaloid, *atherospermine* ($C_{30}H_{20}NO_5$); see also Wittstein's *Organic Constituents of Plants*, 20. The abundant volatile oil is light yellow, and has a pleasant aromatic odor and taste, resembling those of oil of sassafras. Scott obtained from the leaves 1.7 to 2.65 per cent. of volatile oil. (*J. Chem. S.*, 101, 1912, 1612.) Ralph Stockman (*Lab. Rep. Royal Coll. Phys.*, vi, 1897) found it to resemble in its physiological action oil of sassafras and other allied volatile oils. He took repeatedly ten minims (0.6 mil) without any pronounced effect, and one fluidrachm (3.75 mils) given to a rabbit caused only temporary stupor, with slowing of the respiration, but not of the pulse. Three fluidrachms (11.25 mils) caused in the rabbit marked depression of the heart and of the respiration, coma, and death in twelve hours by asphyxia.

Atoxyl. *Sodium Arsanilate. N. N. R.* 1917. $C_6H_4NH_2.(AsO.OH.ONa) + 3H_2O$.—When atoxyl was first introduced into medicine it was supposed to be *metaarsenic anilide* ($C_6H_5NHAsO_2$), but more recent studies have shown it to be sodium arsanilate. It is a white powder soluble in cold water and still more so in warm water. It has a slightly saline taste. On standing the aqueous solution assumes a yellowish tint. It contains 26 per cent. of arsenic.

There is upon the market under the name of *soamin* a substance which appears to be of precisely the same composition as atoxyl, with the exception that it contains five molecules of water instead of three. It therefore contains only 22.8 per cent. of arsenic. The physiological and therapeutic properties of these two substances are the same.

While originally introduced as a means of producing the therapeutic action of arsenic without the toxic disadvantages of that drug, atoxyl owes its notoriety to the results achieved with it by Koch in the treatment of *sleeping sickness* (*D. M. W.*, 1907, p. 200). In this highly fatal disease Koch found that the use of the drug, even in fairly advanced stages, would cause the blood to become free from trypanosomes at least temporarily. Most of the cases, however, eventually relapsed and died of the disease. When the drug was used boldly in the milder cases of the infection, occasionally a permanent cure would result. From the beneficial effects which were produced in *trypanosomiasis*, several clinicians were led to test its efficacy against the biologically allied parasite which is regarded as the causative agent of *syphilis*. While the results in the latter infection were not altogether brilliant, the preparation showed itself to exercise a distinctly toxic action upon the spirochætæ. Blumenthal (*Med. Klin.*, 1907, p. 319) and others have reported more or less favorable results from the internal administration of the drug in *cancers*. It has also been employed against *relapsing fever, malaria, pellagra, leukemia* and *frambesia* with more or less evidence of good effects.

These striking results in some of the most hopeless diseases seemed to foretell for the remedy a most important place among our therapeutic agents. Unfortunately, however, wider experience with the drug showed that it was by no means the innocent remedy which had first been believed. Although the single dose is far less toxic than an equivalent amount of arsenic, when used over long periods of time it produces degenerative changes in various portions of the central nervous system in a large proportion of cases. Igersheimer (*D. M. W.*, 1909, xxv, p. 1142) reports forty-six cases of permanent blindness due to atrophy of the optic nerve following the use of atoxyl. He has also noted in the lower animals histological changes in the brain and in the spinal cord. Schlect (*M. M. W.*, 1909, lvi, p. 971) records fatal results from four injections given on alternate days of 0.6 Gm. each. After death there was found degeneration in the internal organs such as are commonly seen after arsenical poisoning. The number of cases of blindness and even death have been so large that it would seem that the therapeutic use of the drug is scarcely justifiable except in such hopeless infections as the *sleeping sickness*.

It has usually been administered hypodermically in *doses* of from one to three grains (0.06–0.2 Gm.), once every other day.

Atropine Salicylate.—This salt is alleged to have advantages over the sulphate, mainly because of its more rapid and efficient action, provided it be pure and perfectly neutral. It may be prepared by Frederici's process, which is to dissolve 23 parts of atropine in pure alcohol by a gentle heat, and to add enough salicylic acid (about 18 parts) to render the solution neutral, which is determined by the use of litmus paper.

The solution is carefully evaporated, and finally dried in a drying oven. It is deliquescent, and should be kept in securely stoppered vials. The *dose* is the same as that of the sulphate.

Atropine Santoninate, a compound of atropine and santonic acid, is described by Bombelon (*Ph. Ztg.*, April, 1886) as an amorphous non-hygroscopic powder, readily soluble in water, which presents advantages over other atropine salts in being non-irritating, and also in affording a solution which is stable if kept in yellow glass bottles to avoid the formation of photo-santonic acid. One drop of a solution of 0.01 Gm. in 20 mils of water is sufficient to dilate the pupil, the dilatation disappearing in from twelve to twenty-four hours. The powder should be kept in amber-colored vials to protect it from the light.

Atropine Sulphuric Acid.—This organic compound of atropine with sulphuric anhydride occurs in colorless crystals sparingly soluble in water, insoluble in most of the organic solvents, but dissolving readily in ammoniacal solutions. It has been recommended by Phillippstal (*B. K. W.*, 1913) in the treatment of *asthma* and *night sweats.* He claims that it has the advantage over atropine that it does not cause drying of the throat nor tachycardia. The *dose* he employed was one sixty-fourth of a grain (0.001 Gm.).

Azadirachta. *Azedarach, U. S.* 1880. *Pride of India. Pride of China. Ecorce d'Azédarach, Ecorce de Margousier,* Fr. *Zedrachrinde,* G.—The U. S. P. formerly recognized the bark of the root of *Melia Azedarach* L. (Fam. *Meliaceæ*), a beautiful tree, thirty or forty feet high, with a trunk fifteen or twenty inches in diameter. This species of *Melia* is a native of Syria, Persia, and the north of India, and is widely cultivated. It is abundant in our Southern States. North of Virginia it does not flourish. "The bark [root] is in curved pieces or quills of variable size and thickness; outer surface red-brown, with irregular, blackish, longitudinal ridges; inner surface whitish or brownish, longitudinally striate; fracture more or less fibrous; upon transverse section tangentially striate, with yellowish bast fibers; inodorous, sweetish, afterwards bitter and nauseous. If collected from old roots, the bark should be freed from the thick, rust-brown, nearly tasteless, corky layer." *U. S.*, 1880. The bark of the trunk is "externally of a rusty-gray color, internally yellowish, and much foliated; coarsely fibrous; inodorous, bitter and slightly astringent; structure and thickness varying according to age." *Br. Add.* (For a description of the leaves and root bark, see *Ph. Rev.*, 1896, p. 231.)

Oil of Azederach is found of two kinds in Eastern Asia where it is used. One is employed for burning, the other medicinally. The latter oil, according to Lewkowitch (*Oils, Fats, Waxes,* vol. ii, p. 426), is known as *Veepa Oil, Veppam Fat* and *Neem Oil,* and has a specific gravity of 0.914, a saponification value of 196.9, and iodine value of 69.6, a Reichert-Meissel value of 1.1 and a butyro-refractometer reading of 52° at 25° C. (77° F.).

Azadirachta indica Br. Add. *Neem Bark, Margosa Bark.* Under this name was recognized the bark of the stem of *Melia Azadirachta* L., or *Indian Lilac Tree.*—This contains, according to Broughton (*P. J.*, 1873, 992), a bitter amorphous resin, and a crystallizable principle, melting at 175° C. (347° F.). (See also *Ph. Rev.*, 1896, 231.) Cornish (*Ind. Ann. Med. Sci.*, 4, 104) had previously announced the presence of a bitter alkaloid, to which he gave the name *margosine.*

The decoction of azedarach is affirmed to be cathartic and emetic, and in large doses narcotic; but in a number of experiments made by H. C. Wood with extracts from the dried bark and fruit, it was found impossible to poison frogs or rabbits. Robins eating of the sweetish fruit, of which they are very fond, are often rendered so far insensible as to be picked up under the tree; though they usually recover in a few hours. Children are said to eat the fruit without inconvenience, and possibly the robins simply choke themselves with the large berries. The bark is considered, in the Southern States, an efficient anthelmintic. The form of decoction is usually preferred. A quart of water is boiled with four ounces of the fresh bark to a pint, of which the *dose* for a child is a tablespoonful every two or three hours, until it affects the stomach or bowels. Another plan is to give a dose morning and evening for several successive days, and then to administer an active cathartic. The *fresh* bark and the fruit are said to be superior as vermifuges. The Br. Add. recognized an *infusion* (*Infusum Azadirachtæ Indicæ,* Br. Add.), eighty-eight grains in a pint of cold water, *dose,* one-half to one fluidounce (15–30 mils); also a *tincture* (*Tinctura Azadirachtæ Indicæ,* Br. Add.), two ounces in a pint of 45 per cent. alcohol, *dose,* one-half to one fluidrachm (1.8–3.75 mils).

Baccharis. *Baccharis cordifolia* DC. *Mio Mio.*—This composite plant of Southeastern South America is notorious for its deadly effect upon sheep and cattle. Pedro N. Arata has isolated from it an alkaloid *baccharine.* (*P. J.*, x, 6.)

Bacillol is a kresol soap mixture similar to the compound solution of cresol. (See page 631.)

Bactoform.—This preparation consists of a neutral soap solution of formaldehyde and coal tar derivatives. It is used for rendering antiseptic the instruments and apparatus used in surgical operations. A 1 or 2 per cent. solution in water is used for this purpose. Under the name *bello-form* another preparation, identical with Bacto-form, is sometimes employed.

Balanites. *Agialida. Balanites Roxburghii* Planch. (Fam. *Zygophyllaceæ.*)—The fruit of this plant is used medicinally in India. It contains a principle closely resembling saponin. The ripe seed yield about 50 per cent. of a fixed oil (*zachun oil*), which is used for burning. (See *P. J.*, 1913, 905.) The unripe fruit is anthelmintic and purgative.

Balata. *Gum Chicle. Chicle. Tuno Gum. Leche de Popa,* Fr. *Zapota Gum.*—This is the dried milky juice of the *Bully Tree, Mimusops Balata* Gärtn. (*Sapota Muelleri* Linden) of the Fam. *Sapotaceæ,* a native of Northern South America from Mexico to Guiana. It is an oxidized hydrocarbon, both physically and chemically closely related to caoutchouc and gutta-percha, of a grayish-white color, with dark spots and veins; specific gravity 1.05; tasteless, but emitting an agreeable odor when warmed. It has the general properties of gutta-percha, differing, however, in being but slightly extensible, a property which specially fits it for the manufacture of transmission belts. Solid and somewhat crumbling at ordinary temperature, it softens at 49° C. (120.2° F.), and can be molded like gutta-percha. The chemical constituents of chicle have been investigated by Tschirch and Schereschewski who found so-called resins, two of them being crystallizable *a-balaban* and *b-balaban* and a yellow substance, *balafluavil.* (*A. Pharm.*, 243, No. 5, 1905, 358; see also Bosz and Cohen's investigations, *A. Pharm.*,

250, 1912, No. 1, 52; also *P. J. Tr.*, 1910, 609.) It is used as a substitute for gutta-percha, but more especially in the manufacture of chewing gum, for which purpose it is imported in large amounts from Mexico. It is sometimes adulterated with paraffin wax. It is not used in medicine.

Balm of Gilead. *Balsam of Gilead. Mecca Balsam. Balsamum Meccæ v. Judiacum. Balsamum Gileadense. Baume de la Mecque,* Fr.—The genuine balm of Gilead is the resinous juice of *Commiphora Opobalsamum* (L.) Engl. (Fam. *Burseraceæ*), a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and is still esteemed by the Eastern nations as a medicine and cosmetic. In Western Europe and in this country it is seldom found in a state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, becoming solid by exposure. It possesses no medicinal properties not existing in other balsamic or terebinthinate juices. It was formerly known as *opobalsamum*, while the dried twigs of the tree were called *xylobalsamum*, and the dried fruit, *carpobalsamum*. In this country *Poplar buds* are often, incorrectly, called Balm of Gilead Buds.

Balsam of Cativo. *Cativo Balsam.*—This substance appeared in the London market in 1902 as a substitute for copaiba. It is a balsamic resin, opaque, of a dirty light brown color and slightly bitter taste, and having an extremely adhesive quality. According to Umney, it is not soluble in 90 per cent. alcohol, but is soluble in ether and consists chiefly of acid resins with the addition of an oily substance. According to Weigel's analysis it consists of 80 per cent. of resin acids and 2 per cent. of volatile oil. It is supposed to be a product of *Prioria copaifera* Gris. (Fam. *Leguminosæ*), a large tree indigenous to Panama and Jamaica. (See *P. J.*, vol. lxix; and *Ph. Centralh.*, March, 1903.)

Balsam of Cebur or Tagulaway.—*Cebur* or *Tagulaway Balsam* is prepared in the Philippine Islands by boiling the root and twigs of *Parameria vulneraria* Radl. (Fam. *Apocynaceæ*), in cocoanut oil, so as to form a yellowish-white, oily liquid, which is used with asserted excellent results for *skin diseases* and *wounds*. (*A. Pharm.*, Nov., 1885.)

Balsam of Lagam. *Lagam Balsam.*—A thick, yellowish, fluorescent liquid, of a peculiar aromatic odor, and bitterish, acrid taste, resembling copaiba. (*A. J. P.*, 1883, p. 368.)

Balsam of Riga. *Riga Balsam. Balsamum Carpaticum. Balsamum Libam.*—This is the product of *Pinus Cembra*, L. (Fam. *Pinaceæ*), a large tree growing in the mountainous regions and northern latitudes of Europe and Siberia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin, white fluid, having an odor analogous to that of the juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Kronstadt in bottles. Keller, of Darmstadt, affirms that Riga Balsam is the product of the ordinary *Pinus palustris* Mill. A similar product, called *Hungarian balsam*, is obtained in the same manner from *Pinus Pumilio* Haenke, growing on the mountains of Switzerland, Austria and Hungary.

Balsam of St. Thome. *Pan Oleo. Belam Pu.* A balsam obtained from *Santiriopsis balsamifera* (Oliv.) Engl. (Fam. *Burseraceæ*). It is a resinous juice obtained by incisions in the trunk of the tree. It is used as a vulnerary and in diseases of the bladder and bronchi. (*Ap. Ztg.*, 1898.)

Balsam of Sulphur. *Oil of Linseed Sulphurated, Thiolinic Acid. Oleum lini sulfuratum. Oleum Sulphuratum.*—The old Edinburgh Pharmacopœia directed to boil *eight parts* of olive oil and *one part* of sublimed sulphur together, over a gentle fire, in a large iron pot, stirring them constantly until they united. As the vapors which rose were apt to take fire, a lid was to be at hand to cover the pot, and thus extinguish the flame if necessary. In this way the oil was partly decomposed, and the resulting preparation was an extremely fetid, acrid, viscid, reddish-brown fluid, which was formerly used in *pectoral complaints;* but inconvenience arose from its acrid properties, and its internal use was abandoned. It is sometimes applied as a stimulant to *foul ulcers. Haarlem Oil* is a mixture of oil of turpentine with balsam of sulphur. The *dose* is from five to thirty minims (0.3–1.8 mils).

Balsam Wood. *Palo Balsamo.*—This is a South American wood, derived from an unknown tree, which is believed to contain *guaiacin*, and which yields to distillation nearly six parts of a thick viscous aromatic oil. This contains as its chief constituent a crystalline solid of alcoholic character, melting at 91° C. (195.8° F.) and corresponding closely to the formula $C_{14}H_{24}O$. It has found employment in perfumery. (*Schim. Rep.*, April and Oct., 1892.)

Balsamorhiza. *Balsamorhiza terebinthinacea* Nutt. (Fam. *Compositæ.*)—The root of this plant, obtained from Idaho and Oregon, has a strong, terebinthinate odor, and is used medicinally in the Western States. It contains volatile oil, fixed oil, resin, organic acid, and sugar (Herman T. Kelly, *D. C.*, 1897, 32).

Baptisia. *N. F. IV. Wild Indigo. Indigo sauvage,* Fr. *Baptisie,* G.—"The dried roots of *Baptisia tinctoria* (Linné) R. Brown (Fam. *Leguminosæ*), without the presence of more than 10 per cent. of the crown and stem or other foreign matter." *N. F.* This is an indigenous perennial plant, abundant throughout the Eastern United States, in woods and dry barren uplands. The roots are "fleshy, from 0.5 to 4 cm. in thickness, usually cut into elongated cylindrical pieces; the crown from 5 to 8 cm. in thickness, more or less warty and marked by stem scars; outer surface dark-brown; usually longitudinally wrinkled, transversely warty, or the thicker pieces covered with a soft and friable corky layer, bearing few branching rootlets; fracture tough, the fractured surface whitish; bark section radially striate, wood-section inconspicuously radiate, porous. Nearly odorless; the bark bitter and acrid, the wood nearly tasteless. The powdered drug is light-grayish and, when examined with the microscope, shows numerous, rounded, simple, or two- to four-compound starch grains up to 0.016 mm. in diameter, the larger grains sometimes with a cleft through the center; tracheæ with bordered pores up to 0.085 mm. in diameter; numerous sclerenchyma cells, long, thick-walled, non-porous, more or less lignified and up to 0.024 mm. in width; fragments of medullary-ray tissue composed of cells with lignified walls and numerous simple pores; groups of parenchyma, many of the cells filled with starch; few epidermal and cork cells with brownish walls. Baptisia yields not more than 5 per cent. of ash." *N. F.* It contains a glucoside, *baptisin*, an alkaloid, *bapti-*

toxine, and a coloring principle which has been used as a substitute for indigo, but which is greatly inferior. It is not often used in medicine. For further information concerning this drug, see *U. S. D.*, 19th ed., p. 1406 and *A. Pharm.*, 245, 1907, No. 8, 561–572.

Barbados Nuts. *Purging Nuts. Physic Nuts. Semen Ricini Majoris. Pignon d'Inde (des Barbades), Semences du Médicinier*, Fr. *Purgirnuss, Schwarze Brechnuss*, G.—These are the seeds of *Jatropha Curcas*, L. (Fam. *Euphorbiaceæ*), growing in Brazil, the West Indies, and cultivated extensively in all tropical countries. The fruit is a three-locular capsule, containing one seed in each locule, and is about the size of a walnut. The seeds are blackish, oval, 1.5 to 2 cm. long, flat on one side, convex on the other, and the two sides present a slight longitudinal prominence. They yield a fixed oil, an acrid resin, sugar, gum, a fatty acid, glutin, a free acid, and salts. A. Siegel (*Bot. Centralb.*, xlvii, 120) found in the seeds a poisonous principle, *curcin*, which he states is analogous to *ricin*, and places in the class of toxalbumins. The oil, sometimes called *jatropha oil*, may be separated by hot expression, the yield being about 40 per cent. When fresh it is without odor or color, but becomes yellowish and slightly odorous by time. Alcohol does not readily dissolve it. It is colorless, odorless, of sp. gr. 0.91 at 19° C. (66.2° F.), solidifies to buttery consistence at −8° C. (17.6° F.). Bouis believed it to be the glyceride of a peculiar acid, *isocetic acid*, but it is now considered to be a mixture of palmitin and myristin. From three to five of the *seeds*, slightly roasted and deprived of their envelopes, operate actively as a cathartic, and not infrequently produce nausea and vomiting, with a sense of burning in the stomach. The *oil* purges in the *dose* of five to ten minims (0.3–0.6 mil), and is analogous in its action to croton oil, though less powerful. The cake left after the expression of the oil is an acrid emeto-cathartic, operating in the *dose* of a few grains. Either of these substances may produce serious consequences in overdoses. The leaves of the plants are rubefacient, and the juice is said to have been usefully employed as a local remedy in *piles*. (*A. J. P.*, 1893, 335.) The seeds of *Curcas multifidus* (L.) Endl. (*Jatropha multifida* Linn.) have similar properties, and yield a similar oil. This species also grows in Brazil and the West Indies. (See Peckoldt, *A. Pharm.*, 1887, 415.)

Jatropha gossypifolia Linn., of South America, is used as a local application in *leprosy* and to indolent *ulcers*, and probably has similar physiological influence to curcas. *Jatropha urens*, L., must be excessively poisonous, as accidental contact of the wrist of a gardener in Kew with a young plant produced such symptoms that for five minutes the man was thought to be dead. (*P. J.*, April, 1872, 863.)

The roots of the *Jatropha cardiophylla* Muell. Arg. are largely employed in Southern Arizona and Mexico for tanning purposes. According to the analysis of Josiah C. Peacock, they contain, when thoroughly dried, over 5 per cent. of tannic acid. (*A. J. P.*, 1900, 432.)

Barium. *Baryum*, Fr., G. Ba = 137.37.—This is the metal present in *baryta*. It was first obtained in 1808 by Sir H. Davy, who described it as a difficultly fusible metal, of a silvery-gray color, decomposing water readily, and considerably heavier than sulphuric acid. When exposed to the air, it instantly becomes covered with a crust of barium oxide. Barium chloride, barium dioxide, and barium carbonate were formerly official.

Barium Carbonate. $BaCO_3 = 197.37$.—It is the native carbonate, a rare mineral, discovered in 1783 by Withering, in honor of whom it is called *witherite*. It is found in Sweden and Scotland, but most abundantly in the lead mines of Northern England. It occurs usually in grayish, or pale yellowish-gray, fibrous masses, but sometimes crystallized. Its sp. gr. varies from 4.2 to 4.4. It is generally translucent, but sometimes opaque. It effervesces with acids, and, before the blow-pipe, melts into a white enamel without losing its carbon dioxide. It is distinguished from strontium carbonate, with which it is most liable to be confounded, by its greater specific gravity, and by its yielding a light greenish and not a reddish flame upon the burning of alcohol impregnated with its solution in hydrochloric acid. The presence of strontium is indicated by a reddish flame.

When pure, barium carbonate is entirely soluble in hydrochloric acid. Any barium sulphate present is left undissolved. If neither ammonia nor hydrogen sulphide produces discoloration or a precipitate in the hydrochloric acid solution, the absence of aluminum, iron, copper and lead is shown. Lime may be detected by adding an excess of sulphuric acid, which will throw down the baryta as a sulphate, and afterwards testing the clear liquid with sodium carbonate, which, if lime be present, will produce a precipitate of calcium carbonate. Barium carbonate acts as a poison on the animal economy. Its only pharmaceutical use is to prepare barium chloride.

Barium Chloride. *Barii Chloridum. U. S.* 1870. *Chlorure de Baryum*, Fr. *Chlorbarium, Chlorbaryum*, G. $BaCl_2.2H_2O$.—For the method of preparing this salt, see *U. S. D.*, 19th ed., p. 1407 (see also *Reagents*, Part III).

Barium chloride is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with bevelled edges. It dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 106° C. (222.8° F.), the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol impregnated with it burns with a greenish flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates and tartrates, and the alkaline phosphates, borates, and carbonates; also by silver nitrate, *mercurous* salts, and lead acetate. When pure it does not deliquesce. Its solution is not affected by ammonia, which proves the absence of aluminum and ferric oxide, or by hydrogen sulphide, which shows that neither copper nor lead is present. Tannic acid will precipitate the barium from a solution of its chloride, as tannate.

After the whole of the barium has been precipitated by an excess of sulphuric acid, the supernatant liquid is shown to be free from lime by the non-action of sodium carbonate. If strontium be present, an alcoholic solution of the salt will burn with a red flame.

Barium chloride is actively poisonous, causing when given in sufficient doses convulsions, dilatation of the pupil, and death from respiratory failure. According to Laborde (*B. A. M.*, July, 1891), after death the blood remains of a bright red color. In smaller doses it exercises a stimulant

effect upon various muscular tissues. Through its action upon the intestinal muscle it gives rise first to diarrhea and later to cramp-like spasm of both gastric and intestinal muscle. Upon the voluntary muscle it exercises an effect like that of veratrine, causing marked prolongation of the contraction; after death from barium poisoning, fibrillary contractions of the voluntary muscles may continue for a considerable period of time. It stimulates both the vascular and cardiac muscles and in sufficient dose throws the heart into permanent contraction like that produced by digitalis. In moderate dose the pulse rate is increased and the blood pressure greatly elevated. Because of its action upon the circulation it has been suggested as a cardiac stimulant in cases of *heart failure*. According to Lauder Brunton (*Practitioner*, June, 1889), the chloride is a rapidly acting heart stimulant steadying the rhythm and increasing the volume and force of the cardiac contractions. Filippi (*Lo Sperimentali*, 1907), however, asserts that the drug has such a profound influence upon metabolism that it is not suitable for medicinal purposes. It has also been used in veterinary medicine in the treatment of wind colic. A solution of barium chloride was formerly official (*Liquor Barii Chloridi, U. S.*, 1870) which contained 1 troy ounce of barium chloride in three fluidounces of water. The dose of this solution is three minims (0.2 mil). The *dose* of barium chloride is one-half to one and a half grains (0.03–0.1 Gm.).

Barium Dioxide. *Barii Dioxidum. U. S.* 1890. *Barium Peroxide.* $BaO_2 = 169.37$.—"Commercial, anhydrous barium dioxide. It should be kept in well-closed vessels." *U. S.*, 1890.

It is used chiefly for making hydrogen dioxide. Barium forms two oxides, BaO and BaO_2; the former is produced by the action of oxygen or dry air on barium. Barium dioxide, BaO_2, is made by heating barium oxide to about 450° C. (842° F.), when it takes up another atom of oxygen. It is "a heavy, grayish-white, or pale yellowish-white, amorphous, coarse powder, odorless and tasteless. When exposed to the air, it slowly attracts moisture and carbon dioxide, and is gradually decomposed. It is almost insoluble in cold water, with which, however, it forms a definite hydrate, and to which it imparts a decidedly alkaline reaction. Hydrochloric, phosphoric, and most other mineral acids decompose it, producing the corresponding barium salts, and hydrogen dioxide, which remains in solution for a considerable time, if the reaction has taken place in the cold, and an excess of the acid is present. When heated to a bright red heat, barium dioxide fuses, loses oxygen, and is reduced to barium oxide. Barium dioxide should be dissolved by diluted hydrochloric or phosphoric acid without leaving more than a trace of residue. It should contain at least 80 per cent. BaO_2. It is not used medicinally.

Barium Iodide. *Barii Iodidum. Iodure de Baryum*, Fr. *Jodbarium*, G. BaI_2.—This compound may be formed by double decomposition, by adding native barium carbonate in powder to a boiling solution of ferrous iodide. M. Henry, Jr., obtained it by decomposing a solution of barium sulphide by a concentrated alcoholic solution of iodine. Sulphur is precipitated, which is separated by filtration, and barium iodide formed in solution, from which it is obtained in the solid state by rapid evaporation to dryness. Barium iodide crystallizes in small, colorless needles, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition on exposure to the air, barium carbonate being precipitated, and iodine set free, which colors the solution. It has been used by John and Lugol, as an alterative, in *scrofulous affections* and morbid growths. The *dose* is an eighth of a grain (0.008 Gm.) three times a day, gradually increased to three grains (0.2 Gm.).

Barium Oxide or *baryta* ($BaO = 153.37$) may be obtained from the native carbonate by intense ignition with carbonaceous matter, or from the native sulphate by ignition with charcoal, which converts it into barium sulphide, subsequent solution of the sulphide in nitric acid and strong ignition of the nitrate formed, to dissipate the acid. As thus obtained, it is an anhydrous solid, caustic, alkaline, difficultly fusible, and of a grayish-white color. Recently it has been obtained at Niagara Falls by a reaction in which, at the temperature of the electric arc, a small amount of the sulphide obtained by the reducing action of charcoal is made to react with an excess of unchanged sulphate,

$$3BaSO_4 + BaS = 4BaO + 4SO_2$$

Its sp. gr. is about 4. It acts on the animal economy as a poison. When sprinkled with water it slakes like lime, becomes hot, and is reduced to the state of a white pulverulent hydroxide. The same hydroxide is formed in mass when the anhydrous earth is made into a paste with water and exposed to a red heat in a platinum crucible. The excess of water is expelled, and the hydroxide undergoing fusion, may be poured out and allowed to congeal. Barium hydroxide dissolves in water, and forms the reagent called *baryta water*. A boiling saturated solution, as it cools, yields crystals of barium hydroxide containing eight molecules of water of crystallization.

Baryta consists of one atom of barium and one of oxygen. Its chemical formula, is, therefore, BaO. When barium oxide is heated in a current of oxygen or air, it takes up an atom of oxygen and is changed into barium dioxide, BaO_2. When this is heated somewhat higher, it gives off the extra atom of oxygen and becomes BaO again. This power of taking up oxygen from the air and giving it up at a somewhat higher heat is now utilized on a commercial scale in the Brin process for making oxygen, and it is found that this change from BaO to BaO_2 and back again can be effected at one and the same temperature by simply heating first under pressure and then by exhausting and reducing below the normal atmospheric pressure. Barium dioxide is also of growing importance as the material from which hydrogen dioxide, H_2O_2, is made.

Barium Sulphate. *Barii Sulphas.* $BaSO_4$. *Blancfixé. Permanent White.*—Barium sulphate is a heavy, lamellar, brittle mineral, varying in sp. gr. from 4.4 to 4.6. It is generally translucent, but sometimes transparent or opaque, and its usual color is white or pinkish. When crystallized, it is usually in very flat, rhombic prisms. Before the blowpipe it strongly decrepitates, and melts into a white enamel, which, in the course of ten or twelve hours, falls to powder. It is thus partially converted into barium sulphide, and, if applied to the tongue, will give a taste like that of putrid eggs, from the formation of hydrogen sulphide. Barium sulphate, on account of its great insolubility, is not poisonous. It is, however, soluble in a great excess of diluted hydrochloric acid. Ground to fine powder it is often mixed with white lead,

but impairs the quality of that pigment for some purposes; used alone as a pigment it possesses certain advantages over lead compounds. The artificial barium sulphate obtained as a by-product in many chemical manufactures, under the name of *permanent white, terra alba,* or *blanc fixé,* is much used in the arts as a water-color. It is made from both the native sulphate and carbonate. It forms a dazzling white color, unalterable by light, heat, air, or hydrogen sulphide. Barium sulphate is being used to coat the intestines for the purpose of making X-ray pictures (see Gunther, *D. M. W.*, 1911), replacing the more expensive bismuth subcarbonate and stated to be even more efficient.

Barium Sulphide. *Barium Sulphidum.*—An impure form of barium sulphide is found in commerce, containing about 50 per cent. BaS_2. It is used extensively in combination with starch, powdered orris root and other diluents in depilatory mixtures. As it is sometimes abbreviated "Bar. Sulph.," the same as is applied to Barium Sulphate used in X-ray work (which see), care must be taken in dispensing it, as it has on several occasions caused death when taken internally by mistake for barium sulphate.

Barringtonia. *Barringtonia speciosa.*—The large Indo-Malayan tree, *Barringtonia speciosa* Forst. (Fam. *Myrtaceæ*) contains, according to Maresuw, 3.3 per cent. of *barringtonin,* a colorless, amorphous glucoside, having the formula $C_{18}H_{28}O_{10}$, and belonging to the saponin group. It is said to be an active cardiac poison. (*S. W. P.*, xli, 1903, pp. 423, 435.)

Basicin. *Corticin.*—This preparation is a compound of quinine hydrochloride and caffeine. The two substances are dissolved in water. The solution is then heated to a high concentration and allowed to crystallize. It is employed intravenously for *malaria,* internally for *migraine, neuralgia, influenza* and similar ailments. The *dose* is three to eight grains (0.2–0.5 Gm.).

Bassia longfolia L. (Fam. *Sapotaceæ.*)—In this Indian plant, known as *mowrah* by the natives, there has been found a glucoside which was named *mowrin* by its discoverers, Moore, Baker, Young and Sawton. According to these investigators, mowrin has a digitalis-like action upon the heart and a saponin-like effect of destroying red blood cells.

Bassora Galls are cultivated in Persia and Asia Minor, and are exported by way of Smyrna for tanning purposes. They come into commerce ground and pressed into the form of bricks. They contain, on an average, 27 per cent. of tannin.

Bassora Gum. *Caramania Gum. Hog Gum. India Gum. False Tragacanth. Kutera Gum.*—This substance came into commerce originally from the neighborhood of Bassora, on the Gulf of Persia; but is often found mixed with gum brought from other countries, and is said to be the product of the almond and plum trees. It is in irregular pieces, about the same size as tragacanth, brown or yellow, intermediate in the degree of its transparency between gum arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. Only a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum or *arabin,* and, according to Guérin, constitutes 11.2 per cent. The insoluble portion consists of *bassorin,* associated with a small proportion of saline substances, which yield, when the gum is burnt, 5.6 per cent. of ash. The gum is employed to adulterate tragacanth, and for this purpose is sometimes whitened by means of white lead, which can readily be detected, however. It is frequently used as a filler and thickener in the manufacture of certain food products, as cheap ice creams.

Batiator Root.—The root of the *Vernonia nigritiana* Oliver and Hiern. (Fam. *Compositæ*), a widely distributed plant of West Africa, is said to be largely used in Senegal as a febrifuge, emetic, and anti-dysenteric, resembling ipecac somewhat in its therapeutic application. The plant is a composite which climbs to the height of a foot and a half, and yields a root composed of numerous fibers from twenty to thirty centimeters long, slender and grayish-yellow externally, a number of which are united to form an irregular knotty rhizome, unequally spherical at the neck or crown, and covered at this point with silky hairs. The active constituent is a glucoside, *vernonin,* $C_{10}H_{24}O_7$. (Heckel and Schlagdenhauffen, *A. de P.*, Aug., 1888; see also *Zeit. An. Chem.*, 1893, p. 364.) This is a hygroscopic whitish powder, forming a pale yellow solution with water, and only slightly soluble in ether and in chloroform. By the absorption of 2 molecules of water it is split into a resinous body and glucose. Physiological experiments made upon frogs show vernonin to be a cardiac poison of the digitalis group; it is also said to act as a paralyzant to the motor nerve trunks. (*P. J.*, June 30, 1888.)

Baume Tranquille. *Balsamum Tranquillans. Huile de Jusquiame Composee. Oleum Hyoscyami Compositum.*—This preparation of the French Codex consists essentially of a fixed oil holding in solution the active matters of certain narcotic and aromatic plants. According to the Codex the fresh narcotic plants, belladonna, henbane, black nightshade, poppy and stramonium, are boiled with poppy seed in a copper kettle until all their water is driven off, and a gentle heat maintained until the oil acquires a fine green color; the oil is then expressed and the essential oils of lavender, peppermint, rosemary and thyme are added. The preparation is used externally by friction as an anodyne in local pains, but especially to relieve *earache,* a few drops being placed in the ear on a pledget of cotton. The National Formulary preparation is approximately the same as the above, although a little less complex. It is known as *Oleum Hyoscyami Compositum* and consists of a solution of oils of lavender, rosemary and thyme in infused oil of hyoscyamus. (See Part III.)

Baycuru Root.—This is the root of a Brazilian plant, probably the *Statice brasiliensis* Boiss. (Fam. *Plumbaginaceæ*), which is used by the natives as a discutient in glandular swellings and as an astringent gargle. F. A. Dalpe (*A. J. P.*, xiv, 361) believed that he has found in it an alkaloid, *baycurine,* besides volatile oil, gum glucose, etc. C. Symes found in it 12.5 per cent. of tannic acid. (*Newer Mat. Med.*, 51.)

Bdellium.—Under this name have been included various gum resins having little or nothing in common. The commercial Bdelliums are naturally divided into the Indian and the African, but E. M. Holmes, in an elaborate study (*P. J.*, lxi), recognizes five commercial varieties of African Bdellium—namely, 1. Perfumed Bdellium, which is be-

lieved to be collected in Northeastern Africa; 2. African Bdellium; 3. Opaque Bdellium; 4. Hotai Bdellium from the Somaliland, and 5. A non-aromatic acrid gum resin. *Perfumed Bdellium*, or *Habaghadi*, closely resembles in appearance *Somali myrrh*, but has a less bitter, more acrid and peculiar taste which distinguishes it at once from myrrh. *African Bdellium*, proper, occurs in hard, roundish pieces, of a pale to dark grayish-brown color with a resinous unstreaked fracture, dotted with glistening points. The odor is said to recall that of cedar wood; the taste is slightly acrid but not bitter. *Opaque Bdellium* is of a pale brown color and has a bitter, slightly acrid taste and cedar-like odor; it occurs in tough, roundish pieces about an inch to an inch and a half in diameter. *Hotai Resin* resembles opaque bdellium, but is distinguished by its lack of odor, its slightly soapy taste, and its brittleness. These four bdelliums of Holmes are for the most part collected in Somaliland. They are the product of different species of *Commiphora*, small trees or large shrubs which suggest in appearance the English hawthorn. The species are by Holmes divided into four groups. (See *P. J.*, lxxii.) According to A. Engler, the resin of *Commiphora roxburghiana* (Stocks) Engl. is the commercial *Gugul*, or *India Bdellium*, which is employed in the East Indies as a remedy for *leprosy*, *rheumatism*, and *syphilis*. Bdellium sometimes comes mixed with gum arabic and gum senegal. It is either in small roundish pieces, of a reddish color, semi-transparent, and brittle, with a wax-like fracture, or in large irreguliar lumps, of a dark brownish-red color, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odor and taste like that of myrrh, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odor. According to Pelletier, it consists of 59 per cent. of resin, 9.2 of gum, 30.6 of bassorin, and 1.2 of volatile oil, including loss. In medicinal properties it is analogous to myrrh, and was formerly used for the same purposes. In Europe it is still occasionally employed in plasters. The *dose* is from ten to forty grains (0.65–2.6 Gm.).

Bebeeru Bark.—*Nectandræ Cortex*, Br. 1885, is the dried bark of *Nectandra Rodiæi* Hook. (Fam. *Lauraceæ*). The *bebeeru*, *bibiru* or *sipiri*, as it has been variously named, is a tree sixty feet or more in height, growing in British Guiana and the neighboring regions of South America, and yielding the wood known as *greenheart*.

The bark occurs in large, flat, heavy pieces, from 30 to 60 cm. long, from 10 to 15 cm. broad, and about 6 mm. thick, with a short, granular fracture, of a grayish-brown color on its outer surface and a dark cinnamon color on the inner. It has an intensely bitter, somewhat astringent taste. On microscopical examination it is seen to be composed chiefly of very thick-walled parenchymatous cells. The inner bark contains peculiar short, sharp-pointed, undulate bast fibers. Within the cells dark brown masses (colored greenish-black by ferrous sulphate) may be seen. Analyzed by Maclagan, of Edinburgh, it was found to contain tannic acid of the kind that precipitates the salts of iron green, resin, gum, sugar, albumen, fibrin, various salts, and two peculiar alkaloids, named respectively *bebeerine*, $C_{19}H_{21}O_3N$, and *sipirine*, the former soluble and the latter insoluble in ether. In the seeds, besides the foregoing principles, Maclagan found 53 per cent. of starch, and a peculiar white, crystalline, volatile acid, which he named *bebeeric acid*. The alkaloids are extracted together from the bark, in the form of impure sulphate, by a process similar to that for preparing quinine sulphate. This preparation was formerly known as the *commercial bebeerine sulphate*. The sulphate, hydrochloride and alkaloid are all used in medicine, the *dose* of either being from one to two grains (0.065–0.13 Gm.). According to Flückiger (*P. J.*, xi, 193, 1869), pure bebeerine is a white, amorphous powder, whose concentrated aqueous solution is not precipitated by tartar emetic, but affords abundant white precipitates with sodium phosphate, potassium nitrate, iodide, or iodohydrargyrate, mercuric chloride, potassium platinocyanide, and nitric or iodic acid. Its acetate yields yellow amorphous precipitates with potassium ferrocyanide, potassium ferricyanide, potassium chromate, potassium dichromate, or platinum dichloride. D. B. Dott has confirmed the results of Flückiger's examination, although he found a larger percentage of alkaloids than the latter did. Owing to the difficulty of obtaining the alkaloids in crystals, it was almost impossible to ascertain the quantity present. (*Y. B. P.*, 1881, 442; 1885, 420.) Bebeerine was asserted by Walz, in 1860, to be identical with *buxine*, obtained from *Buxus sempervirens*. This statement was confirmed by Flückiger, who proved that *pelosine* was identical with both of the above principles. (*P. J.*, xi, 1870, 192.) (Palen gives $C_{19}H_{21}NO_3$ as the formula.)

By treating the mixed alkaloids obtained from the wood with chloroform, Douglas Maclagan and Arthur Gamgee have separated an alkaloid, *neotandrine*. It is a white powder, amorphous, and intensely bitter. It differs from bebeerine in being much less soluble in ether, and, when treated with strong sulphuric acid and manganese dioxide, in giving rise to a magnificent green, slowly passing into a beautiful violet, and, lastly, in having a higher molecular weight, its formula being $C_{20}H_{23}NO_4$. After separating nectandrine from the mixed bases, the authors succeeded in extracting another alkaloid, different from bebeerine, much more soluble in water than nectandrine, but insoluble in chloroform. (*A. J. P.*, 1869, 453.)

Nectandra is reputed to resemble cinchona in its virtues, although much inferior. It has generally been employed in the form of the impure bebeerine sulphate. In some cases of *intermittent* and *remittent fevers* it has apparently exercised a curative effect but it often fails, and cannot be relied on as a substitute for quinine. Bebeerine sulphate has been given in *dysmenorrhea*, *menorrhagia*, and *leucorrhea*. The *dose* is from two to five grains (0.13–0.32 Gm.). In *malaria* from ten to thirty grains (0.65–0.9 Gm.) may be given, in divided doses, between the paroxysms.

Bedeguar. *Fungus Rosarum.*—An excrescence upon the *sweetbrier* or *eglantine*, *Rosa rubiginosa*, and other species of *Rosa*, produced by the puncture of insects, especially by one or more species of *Cynips*. It is of irregular shape, usually roundish, about an inch in diameter, with numerous cells containing larvæ. It is nearly odorless, of slightly astringent taste, and was formerly considered a diuretic and anthelmintic. *Dose*, from ten to forty grains (0.65–2.6 Gm.).

Benzacetin. *Acet-amido-ethyl Salicylic Acid.*

$C_6H_3\begin{cases}OC_2H_5\\NH.COCH_3\\COOH\end{cases}$.—This occurs in colorless crys-

tals, melting at 205° C. (401° F.), sparingly soluble in water. It has been recommended by Frank as an analgesic in *migraine* and other forms of *neuralgia*, and as a sedative in nervous excitement. It has been used with alleged excellent results in conjunction with caffeine, ten parts to one. *Dose*, from eight to fifteen grains (0.5–1.0 Gm.) two or three times a day, or repeated in an hour for relief.

Benzanilid.—*Phenylbenzamide*, $C_6H_5NH(C_7H_5O)$, is closely related to acetanilid, containing the benzoyl radical C_7H_5O instead of the acetyl radical C_2H_3O. White to reddish, crystalline, odorless powder melting at 163° C. (325.4° F.), practically insoluble in water but soluble in alcohol. This substance has been recommended by Cahn as an antipyretic in diseases of children in *doses* of from one and a half to three grains (0.096–0.2 Gm.) for children one to three years of age; for adults the dose is ten to fifteen grains (0.65–0.9 Gm.). It has been little used.

Benzidine. (*Paradiaminodiphenyl.*) $(C_6H_4)_2(NH_2)_2$. *N. N. R.* 1917.—A grayish-yellow crystalline powder, difficultly soluble in cold water, more readily in boiling water. This substance, especially in the form of its hydrochloride, has attained a considerable use as the means of detecting the presence of occult blood. For ordinary purposes the benzidine paper is sufficiently accurate. The method of using this is to immerse the benzidine paper in the liquid suspected of containing blood and then drop upon it some hydrogen dioxide solution, and if blood be present there is produced within a minute a blue color. The blue color, however, will appear after a period of time even although no blood may be present. According to Einhorn, it may be assumed that if the blue color appears within a minute blood is present and if not that it is absent. A more satisfactory method of use is that which has been suggested by Ascarelli. (*D. M. W.*, 1908, p. 2307.) He uses a solution composed of 2 mils of a saturated alcohol solution of benzidine, 2 mils of 3 per cent. hydrogen dioxide solution and one or two drops of glacial acetic acid. This is mixed with the suspected substance and if blood be present there will immediately occur a blue color. The test appears to be much more delicate than the ordinary guaiac test. Walter (*D. M. W.*, 1909, p. 130), who employs sodium perborate instead of hydrogen dioxide, asserts that blood may be detected in a dilution of one in 100,000 parts; in fact, for the clinical detection of occult blood in the feces, the test is too delicate, for a sufficient amount of blood may occur in excreta to react to this test and yet have no pathologic significance. Schumm (*A. Pharm.*, 1909) says that the method is not absolutely reliable because other oxidizing agents, as salts of iron oxide and the sulpho-cyanides, will give a positive reaction with benzidine.

The pharmacological properties of benzidine have been investigated by Adler (*A. E. P. P.*, 1908, lviii, p. 167) who found that large doses exercised a paralytic effect upon the central nervous system and caused the appearance of glycosuria and degeneration of the red blood corpuscles. It was oxidized in the body and eliminated as diaminodioxyphenyl.

Benzoin. *Benzoin Æstivale* (L.) Nees. *Lindera Benzoin* Blume. (Fam. *Lauraceæ*.) *Spicewood. Spice-bush. Fever-bush. Benjamin Bush. Wild Allspice. Laurier Benzoin*, Fr. *Benzoelorbeer*, G.—An indigenous shrub, occurring in damp woods, throughout the Eastern and Central States, all parts of which have a spicy, agreeable flavor, strongest in the bark and berries. By warming and expression A. W. Miller obtained from the berries 50 per cent. of oily material, which, on distillation, yielded about 2 per cent. of volatile oil. The latter had a sp. gr. of 0.850, was thin, bright green, of a warm aromatic taste, and a fragrant odor. J. M. Jones found it to be of the cinnamyl series. (*Proc. A. Ph. A.*, xxvi, 772; also *A. J. P.*, xlv, 300; xlvii, 246.) The small branches are said to be employed in the form of infusion or decoction, by the country people, as a vermifuge, and an agreeable drink in *low fevers*, and the bark has been used in *intermittents*.

Benzo-Iodo-Hydrine. $C_3H_5ClC_7H_5O_2$.—Prepared by mixing *benzoyl iodide* and *epichlorhydrin*. It forms a brown, fatty mass, soluble in ether, alcohol, and petroleum oils, insoluble in glycerin. It is decomposed at 100° C. (212° F.), with separation of iodine. For dispensing, it is usually mixed with powdered sugar, so that the mixture contains 3¼ per cent. of benzo-iodo-hydrine, and a teaspoonful is about the equivalent of sixteen grains of potassium iodide. It is used as a substitute for potassium iodide, because of its freedom from irritating properties and from tendency to produce iodic poisoning.

Benzo-Naphthol. *N. N. R.* 1917. *Betanaphthol Benzoate. Benzoyl-Naphthol. β-Naphthyl Benzoate.* $C_6H_5COOC_{10}H_7$.—This compound is made by the action of benzoyl chloride upon β-naphthol. It is a whitish, crystalline powder, without taste or odor, melting at 110° C. (230° F.) and prone to darken with age. It occurs in microscopical crystals, almost odorless and tasteless, nearly insoluble in water at ordinary temperatures, more soluble in alcohol, with solubility rising rapidly with the temperature, but most soluble in chloroform. "A hot alcoholic solution should not give any cherry-red coloration when an equal volume of nitric acid and a few drops of mercuric nitrate solution are added, which would indicate the presence of free β-naphthol." This substance, which was proposed by Yvon and Berlioz (*Pract.*, Dec., 1891) as especially efficacious as an intestinal antiseptic, has been reported upon by Gilbert (*S. M.*, May, 1892), who affirms that it is of little value in *gastric fermentation*, but very valuable in *intestinal fermentation*. It is probably slowly broken up in the intestines into benzoic acid and naphthol, and the experiments made by Ewald (*B. K. W.*, 1892) indicate that it has a positive influence upon intestinal fermentation, a conclusion confirmed by various French clinicians. It appears to be free from irritant properties, and to be a very useful remedy in chronic *diarrhea*; also in *senile pruritus* dependent upon intestinal indigestion. It is best administered in small *doses* of from four to eight grains (0.26–0.5 Gm.), repeated frequently, in capsule; as much as seventy-five grains (5 Gm.) daily may be given to an adult. It is incompatible with antipyrine, camphor, phenol, ferric chloride, menthol, potassium permanganate or ethyl carbonate.

Benzo-Phenoneid. *Tetra-methyl-diapsido-benzo-phenoid.*—This substance, which is soluble in 100 parts of water, has been proposed by Galezowski as a non-irritant and efficient germicide, and as a local application in ulcerative diseases of mucous membranes or skin. (*L. L.*, Jan., 1891.)

Benzosalin. *N. N. R.* 1917. $C_6H_4\begin{cases}O.COC_6H_5\\COOCH_3\end{cases}$

Methyl-benzoyl Salicylate.—This compound is the methyl ester of benzoyl salicylic acid. It occurs as white, acicular crystals which melt at 85° C. (185° F.), insoluble in water, sparingly soluble in ether, but readily soluble in alcohol and chloroform. It is incompatible with acids or highly acid salts. This compound is asserted to pass through the stomach unchanged and be split up by the intestinal juices into its component parts, salicylic and benzoic acids, which exercise their characteristic antiseptic action upon the bowels, and after absorption their anodyne and antirheumatic properties. It has been employed with success in the treatment of *articular* and *muscular rheumatism* and in *neuritis, neuralgia* and similar conditions where the coal tar analgesics are of service. Freund (*D. M. W.*, 1907) believes that the benzoic acid lessens the excessive sweating as well as the local irritant action produced by salicylic acid. The *dose* is eight to fifteen grains (0.5–0.9 Gm.) three or four times a day.

Benzosol. *N. N. R.* 1917. *Benzoyl Guaiacol. Guaiacol Benzoate.*—A colorless, crystalline powder, almost free from odor and taste. It melts at 59° C. (138.2° F.). It is prepared from guaiacol, $C_6H_4\begin{cases}OCH_3,\\OH\end{cases}$ and benzoyl chloride, or benzoic acid, and has the formula $C_6H_4\begin{cases}OCH_3\,(1)\\OCO.C_6H_5\,(2)\end{cases}$ The compound is insoluble in water, soluble with difficulty in hot glacial acetic acid, readily so in chloroform, ether, and hot alcohol. In the digestive tract, it soon splits up into guaiacol and benzoic acid; this decomposition occurs partially in the stomach, but chiefly in the small intestine. It is said to appear in the urine as guaiacol and benzoic acid, and their derivatives. Benzosol is incompatible with alkali hydroxides.

Benzosol was first made by Bougartz, and highly commended by Walzer and Hughes (*D. M. W.*, 1891) as a substitute for creosote in *phthisis*, and has been used to a considerable extent by clinicians as an intestinal antiseptic in *intestinal indigestion, diarrhea*, and other conditions. It has also been used successfully in *cystitis*, and is affirmed by Piatokowski, J. Blake White, and others to be valuable in the treatment of *diabetes*. *Dose*, five to ten grains (0.3–0.6 Gm.) several times a day.

Benzoyl-acetyl-peroxide. *N. N. R.* 1917. *Benzozone. Acetozone. Acetyl Benzyl Peroxide.* $C_6H_5CO.O.O.CH_3CO$.—The pure peroxide forms a white, crystalline mass melting at 36.6° C. (98° F.). When gradually heated it slowly decomposes and evaporates; if suddenly heated it almost instantly decomposes and in a tightly-stoppered bottle an explosion will follow. Grinding, compressing, or pounding the undiluted substance will often bring about the same result. In crystalline form, the substance is soluble in oils to the extent of about 5 per cent., slightly soluble in alcohol, moderately soluble in ether, chloroform, and carbon tetrachloride, although gradually decomposed by all the solvents with the exception of neutral petroleum oils. It is decomposed by contact with alkaloids and organic matter of all kinds. It is slowly hydrolyzed and decomposed by water. Acetozone of the markets is benzoyl-acetyl-peroxide diluted with a neutral drying powder so that 50 per cent. of the pure article is represented. Benzoyl-acetyl-peroxide is moderately soluble in water so that fifteen grains of it may be dissolved in one-half gallon of boiled or distilled water; the solution should be used within thirty-six hours after it is made. If the commercial drug be employed, thirty grains may be used in the half gallon; the solution should be allowed to settle and be decanted without filtration. A mixture of acetyl-benzoyl-peroxide and chlorbutanol (chloretone) in liquid petrolatum is known as *acetozone inhalant*.

Benzoyl-acetyl-peroxide is a very active germicide. Experiments in the laboratories of the United States Government in the Philippines show that 1 part of the hydrolyzed substance to 177 of water, and containing only 0.05 per cent. of active oxygen, destroys all germs, including spores, almost instantly; even at a dilution of 1 in 3000, vegetating germs, as a rule, are killed within one minute, but the spores require an appreciable time. It was further shown that 1 part in 1000 absolutely destroys and that 1 in 30,000 distinctly inhibits the growth of the comma bacillus. In the experiments of Ferer and Novy (*Am. Chem. J.*, vol. xxvii, No. 3, March, 1902), one drachm (3.9 Gm.) of it a day, given for several weeks to a dog weighing eight kilos, produced no sensible effect. Charles L. Bliss has shown that acetozone is eliminated in the form of hippuric acid. In internal medicine benzoyl-acetyl-peroxide has been used in the United States hospitals with most excellent results in the treatment of *cholera*, given in double capsules in *doses* of from three to five grains (0.2–0.32 Gm.) every two to four hours. It was found that when the stomach was full at the time of administration vomiting frequently occurred, probably being due to the decomposition of the peroxide by the organic matter present, since no irritation was produced when the stomach was empty. Benzoyl-acetyl-peroxide has been employed by Wasdin, and subsequently by Harris and others (*T. G.*, 1902–1903), in *typhoid fever* with alleged most extraordinary results in the reduction of the local and general symptoms—one hundred and thirty to two hundred and ten grains (8.3–13.6 Gm.) being administered in the twenty-four hours. Acetozone has also been employed locally as a germicide in *gonorrhea, malignant edema, tinea tonsurans, infected ulcers*, and similar affections. In surgical cases acetozone may be applied directly to the wound. When used as an intestinal antiseptic in typhoid fever or in conditions similar to those resulting from this disease, a 1 in 1000 solution should be freshly prepared each day, and administered almost *ad libitum*.

Benzoyl Ecgonine. $C_{16}H_{19}O_4N + 4H_2O$.—This substance is made by heating cocaine in aqueous solution to decomposition. For details, see Paul, (*P. J.*, Oct. 17, 1885, March 27, 1886); (also Skraup, *Sitzungsb. Wiener Akad.*, 1885). The reaction consists in the substitution in cocaine [$C_{16}(CH_3)H_{18}O_4N$] of an atom of hydrogen (H) for the methyl group (CH_3). There results $C_{16}(H).H_{18}NO_4$ or $C_9H_{14}(C_7H_5O)O_3N$ = benzoyl ecgonine; while CH_3OH (methyl alcohol) is formed at the same time. M. R. Stockman (*J. A. P.*, vol. xxi) finds that it acts like caffeine, but less powerfully. It does not paralyze the sensory nerves.

Benzoyl-Eugenol.—*Benzeugenol*, $C_{10}H_{11}(C_7H_5O)O_2$, occurs in colorless prisms or crystals, melting at 70.5° C. (158.9° F.), soluble in alcohol, ether, and chloroform, insoluble in water. It is similar in its properties and medicinal uses to *cinnamyl-eugenol*, $C_{19}H_{18}O_3$. Both are used as antiseptics and in the treatment of *tuberculosis*.

Benzoyl Para Cresol. *Para kresol benzoate. Cresol Benzoate.*—This substance is prepared by the addition of para cresol to a solution of benzoyl

chloride previously rendered alkaline. It occurs in colorless crystals insoluble in water, soluble in alcohol and ether. As an intestinal antiseptic it is given in *doses* of four to five grains (0.25 Gm.).

Benzoyl Succinyl Peroxide—This occurs as a colorless, crystalline substance with an aromatic odor, and a warm taste, soluble in chloroform and in alcohol. In water it is decomposed, liberating benzoic and succinic acids. It has been brought forward as an antiseptic.

Benzoyl Superoxide. *Benzoyl peroxide. Lucidol.* $C_6H_5.CO.O.O.CO.C_6H_5$.—Sodium peroxide and benzoyl chloride are dissolved in water and heated. The resulting product is filtered and the crystals in the filter are washed with warm alcohol. The crystals of benzoyl superoxide are lustrous, white and prismatic, almost insoluble in water but a little more soluble in alcohol. According to Loevenhart (*Th. M.*, 1905, p. 426), it exercises a more powerful oxidizing effect than even hydrogen peroxide. When locally applied it is non-irritant. He recommends it as an antiseptic and analgesic application, either used pure in the form of a dusting powder, or in the form of a 10 per cent. ointment in *burns* and *skin diseases.*

Benzoyl Tropeine, $C_{15}H_{19}O_2N + 2H_2O$, is formed by heating tropine with benzoic and dilute hydrochloric acids to 100° C. (212° F.), when the benzoyl radical, C_7H_5O, derived from benzoic acid, $C_6H_5CO.OH$, replaces a hydrogen atom of the tropine, $C_8H_{15}NO$, and $C_8H_{14}(C_7H_5O)ON$ is produced. It forms silky needles, fusing at 58° C. (136.4° F.). When deprived of water, the anhydrous base fuses at from 41°–42° C. (105.8°–107.6° F.), and can be sublimed without decomposition. It has a strong basic reaction, and its salts are not very stable.

Filehne (*B. K. W.*, vii, 1887) has found that benzoyl tropeine is a powerful local anesthetic, also affecting the pupil and accommodation like other tropeines. He also found other benzoyl compounds to be local anesthetics, *benzoyl methyltriacetonalkamine* being the most powerful, *benzoyl quinine* next, *benzoyl morphine* the least.

Betaine.—This is an alkaloid of weak basic properties which Scheibler discovered in the juice of the sugar beet. (*A. J. P.*, xli, 559.) Husemann showed it to be identical with *lycine*, and to have the composition $C_5H_{11}NO_2$. (*A. J. P.*, 1875, 209.) Liebreich also obtained it by the oxidation of choline, and called it *oxyneurine*. (*Ber. d. Chem. Ges.*, iv, 735.) It has been made synthetically, and its relation to choline and similar compounds established. It is now known to be *trimethyl glycocoll*, $\begin{matrix} CH_2.N(CH_3)_3 \\ | \\ COO \end{matrix}$.

Waller and Plimmer (*P. J.*, lxxi, 517) find that betaine is feebly but distinctly toxic. In dose of 0.1 Gm. per kilo it produced in rabbits fall of blood pressure with final paralysis of the heart. They assert that pure betaine is less poisonous than the commercial. Boger and Josué (*S. M.*, 1898) believe that they have shown that betaine is capable of neutralizing tetanus toxin. Pelicaut (*Press. Med.*, 1904, p. 485) has recorded one case of recovery in which the alkaloid was used in *doses* of eight grains (0.5 Gm.) hypodermically twice a day. Since, however, both chloral and antitoxin were employed in this case, it is doubtful whether the favorable results were due to the betaine.

Betaine Hydrochloride. N. N. R. 1916. *Acidol. Lycine hydrochloride.* $C_5H_{11}NO_2HCl$.—It is prepared by the action of hydrochloric acid on betaine and consists of colorless crystals, freely soluble in water, and contains 23.8 per cent. absolute hydrochloric acid. When dissolved in water it gradually liberates the acid, and has been used by Flatow (*D. M. W.*, 1905) and others as a substitute for hydrochloric acid in *gastric indigestion. Dose*, eight grains (0.5 Gm.).

Beta-Naphtholsulphonic Acid. *Acidum Betanaphtholinsulphonicum.* $C_{10}H_6(OH).SO_3H$.—*Betanaphtholinsulphonic acid* occurs in white pearly scales, tinged with red. It is readily soluble in water and alcohol, and is of medical interest as a test for albumin in the urine. According to E. Riegler, the reaction is so delicate that it will make plainly visible the presence of one part of albumin in forty thousand of water. Albumoses and peptones are also thrown down, but such precipitates disappear on the application of heat, which does not occur with albumin. *Riegler's test* is best performed by adding from twenty to thirty drops of a 5 per cent. aqueous solution of the reagent to five or six milliliters of the urine.

Beta-Sulpho-pyrin. *Antipyrin Sulphanilate. Sulfopyrine.*—This combination of antipyrin with sulphanilic acid consists of a white powder fairly soluble in warm water and having a pronounced acid taste. It is asserted to be a specific in the treating of *iodism* and is also used in *asthma* and *influenza*, etc. *Dose*, fifteen grains (1 Gm.) three or four times daily.

Betol. *Naphthalol. N. N. R.* 1917. *Naphthosalol. Salinaphthol. Salicylic-naphthyl ester. Betanaphthyl Salicylate. Salicylic acid ester of β-naphthol.* $C_6H_4OH.CO.O.(C_{10}H_7)$.—Betol occurs in white, shining crystals, is odorless and tasteless, melts at 95° C. (203° F.), and is insoluble in cold or hot water, soluble in cold alcohol with difficulty, but readily dissolves in hot alcohol (1 in 3), in ether, and in benzene. It is not decomposed by acids or alkalies in the cold, but the alkaline pancreatic fluid has the power to decompose it into β-naphthol and salicylic acid.

Betol was proposed by Sahli as a substitute for salol, on the ground of its being less disagreeable and yielding in the intestines naphthol instead of the more poisonous phenol. It contains, however, 10 per cent. less salicylic acid than does salol, and, having a much higher melting point, splits up much less readily in the intestines; a fact which gains importance from the observation that frequently salicylic acid cannot be found in the urine after its ingestion. Sahli has given as much as one hundred and eighty grains (11.6 Gm.) in twenty-four hours. Betol may be used in *rheumatism*, and is especially commended by Kobert in ammoniacal *cystitis*. Butter of cacao will dissolve one-fourth of its weight of betol, so that suppositories or bougies are readily made. *Dose*, four to eight grains (0.26–0.5 Gm.).

The *salicylic ester of α-naphthol*, an isomer of betol, is known as *alphol*. It is also said to resemble salol in therapeutic effect. The *dose* is from eight to fifteen grains (0.5–1.0 Gm.).

Betonica. *Betonica officinalis*, L. *Wood Betony.*—A perennial European labiate herb, feebly aromatic and astringent. Its root has been considered emetic and purgative.

Betula. *Betula alba* L. *Paper, Canoe or European White Birch. Bouleau*, Fr. *Birke*, G. (Fam. *Betulaceæ.*)—Various parts of this tree have been applied to medicinal uses. The young shoots and leaves secrete a resinous substance, having acid properties, which, combined with alkalies,

is said to produce the effects of a tonic laxative. (*J. P. C.*, xxvi, 208.) The *inner bark*, which is bitterish and astringent, has been employed in *intermittent fever*. The epidermis is separable into thin layers, which may be employed as a substitute for oiled paper, and applied to various economical uses. The bark contains *betulin*, or *betula camphor*, which Hausemann (*Ann. Ch. Ph.*, 182, 368) has shown to be a diatomic alcohol, as it forms a diacetate. Its formula is $C_{36}H_{60}O_3$, fusing point 258° C. (496.4° F.). When oxidized it yields *betulinic acid*, $C_{36}H_{54}O_6$, and *betulinamaric acid*, $C_{36}H_{52}O_{16}$. When the bark is distilled, it yields an empyreumatic oil known variously as *dagget, oleum rusci, oleum betulinum, oleum muscoviticum, oleum fagi*, and *oil of birch tar*. This is a thick, brownish-black liquid, sp. gr. 0.955, having the odor of Russia leather, in the preparation of which it is employed. This oil has been found very useful as a local application in *chronic eczema* and other *skin diseases* in strengths varying between 1 and 20 per cent. Its medicinal properties closely resemble, if they be not identical with, those of oil of cade. (See *Oleum Cadini*, Part I.) Dutch and German *oil of birch* are quite different from the Russian oil. (See *P. J.*, xv, 769.) The National Formulary IV has introduced a rectified oil of birch. See *Oil of Birch Tar*. The *leaves* of birch, which have a peculiar, aromatic, agreeable odor, and a bitter taste, have been employed, in the form of infusion, in *gout, rheumatism*, and *dropsy*. Active diuretic properties are claimed for birch leaves and attributed to the *betulorentinic acid* in them. An alcoholic extract has been used in daily *doses* of from twenty-five to fifty grains (1.6–3.2 Gm.). When the stem of the tree is wounded a saccharine *juice* flows out which is considered useful in complaints of the kidneys and bladder, and is susceptible, with yeast, of the vinous fermentation. A beer, wine, spirit, and vinegar are prepared from it in some parts of Europe. *Tinctura Rusci* is made, according to Hager, as follows: Ol. Rusci 10, Alcohol, Æther, of each 15, Ol. Lavandulæ, Ol. Rosmarini, Ol. Rutæ, of each 0.4 part; filter. (*A. J. P.*, 1881.)

Bezoar.—This name has been given to concretions formed in the stomach or intestines of animals, which were formerly thought to possess extraordinary medicinal virtues. Many varieties have been noticed; but they were all arranged in two classes, the *oriental bezoar* (*lapis bezoar orientalis*), and the *western bezoar* (*lapis bezoar occidentalis*); the former was most esteemed. The bezoars are essentially impure calcium phosphate, except in the vegetable bezoars where the concretions are made up of plant hairs.

Bichetia. *Bichetia officinalis. Mureré Juice* is extracted in Brazil from the incised bark of this plant; it is a thick reddish liquid, sp. gr. 1.100, and is said to contain an alkaloid and to be useful in *rheumatism* and *syphilis*. The *dose* of the juice is one fluidrachm (3.75 mils) in water; in large doses it is drastic.

Bidens. *Bidens bipinnata*, L. *Spanish Needles.*—An indigenous composite plant, of which the root and seeds are popularly used as emmenagogues, and by the eclectics in *laryngeal* and *bronchial diseases*.

Biodal. *Monoiodo-dibismuth-methylene-dicresotinate.*—A pink, odorless, insoluble powder, suggested as a substitute for iodoform.

Bird-Lime. *Bird-glue. Vogelleim*, G.—A viscid substance, existing in various plants, particularly in the bark of *Viscum album* L. (mistletoe), and *Ilex Aquifolium* L., or *European holly*, from the latter of which it is usually procured. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing the latter in proper vessels in a cool situation, where it is allowed to remain till it thickens, when it is washed to separate impurities. Bird-lime thus prepared is greenish, tenacious, glutinous, bitterish, and of an odor analogous to that of flaxseed oil. Exposed to the air in thin layers it becomes dry, brown, and pulverizable, but reacquires its viscidity upon the addition of water. It is a complex body, but is thought to owe its characteristic properties to a proximate principle, which is called *glu* by the French chemists. This principle is without odor or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by ether and oil of turpentine. According to Macaire, it is insoluble in the fixed oils, either hot or cold, a property which distinguishes it from the resins. Macaire proposed for it the name of *viscin*. (*J. P. C.*, xx, 18.) Its analysis corresponds to the formula $C_{20}H_{48}O_8$ (or possibly $C_{30}H_{32} + 8H_2O$). After the extraction of the viscin by ether, Reinsch found a substance soluble in oil of turpentine which he called *viscaoutchin*, because of its elastic caoutchouc-like character. He gives it the formula $C_8H_{16}O$. Bird-lime is so tenacious that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it, are unable to escape.

Under the name of *viscum aucuparium verum*, or *viscin*, bird-lime has become a commercial substance which, when dissolved in benzene, gives a syrupy, intensely green solution capable of any degree of concentration, and possesses extraordinary adhesive powers, adapting it for use as the basis of plasters and also as a vehicle for various dermatological remedies. The ordinary base of *viscin plasters*, as proposed by Riehl, consists of a mixture of 1500 Gm. [or 52 oz. av., 399 grains] of solution of viscin, 100 Gm. [or 3 oz. av., 231 grains] of powdered orris, 400 Gm. [or 14 oz av., 48 grains] of starch, to which are added 280 Gm. [or 9 oz. av., 384 grains] of Venice turpentine, and 31 Gm. [or 1 oz av., 41 grains] of Dammar gum, the whole reduced to a paste by evaporation. In the preparation of salicylic viscin plasters the same formula is followed, excepting that the last two substances are replaced by 5 to 10 per cent. of salicylic acid. Various viscin plasters are made with mercury, iodoform, and other active substances. *Zincum viscosum* is a viscin solution of the consistency of linseed oil, containing 10 per cent. of zinc oxide. For medicinal properties of mistletoe, see *Viscum*.

Bismal. $4C_{15}H_{12}O_{10} + 3Bi(OH)_3$. *N. N. R.* 1916.—The bismuth salt of methylene-digallic acid. A grayish-brown powder, insoluble in water or the gastric juice, but soluble in alkaline solutions. It is used as an astringent in *diarrhea*, especially in prolonged cases that are not benefited by opium treatment. The color of this compound becomes darker with age and is found to vary from yellow to dark brown. *Dose*, from one and one-half to five grains (0.096–0.32 Gm.).

Bismon. *Colloidal Bismuth Oxide.* *N. N. R.* 1917.—A substance said to be produced by the reaction between bismuth salts and alkaline solutions of *sodium lysalbinate* or protalbinate. It occurs as a translucent amorphous mass, contain-

ing 22.3 per cent. of bismuth oxide; freely soluble in warm or cold water, the solution up to 25 per cent. being a reddish-yellow and slightly opalescent tasteless fluid; when stronger, syrupy or gelatinous. It has been highly recommended in the treatment of *gastro-intestinal catarrh*, especially in infants. It cannot be used hypodermically on account of its tendency to produce local disturbances and nephritis. Eighty minims (5 mils) of a 10 per cent. aqueous solution may be given three or four times a day to young children, and *doses* of fifteen grains (1 Gm.) are said to be borne without difficulty by older children; always given in solution and not in powder.

Bismutan. *Isutan.*—A yellow, odorless powder, consisting of bismuth, resorcinol, and tannin.

Bismuth Albuminate. *Bismuthi Albuminas. Bismuthum Albuminatum. Wismutalbuminat*, G. *Bismuthose.*—A compound of indefinite composition made by adding a solution of 75 parts of dried egg-albumin to 25 parts of bismuth and ammonium citrate dissolved in a small quantity of water and drying the product at a low temperature.

A pale gray or white powder, not wholly soluble in water, containing from 10 to 12 per cent. of bismuth. It is used in gastric and intestinal cramps in *doses* of from eight to fifteen grains (0.5–1.0 Gm.).

Bismuth Benzoate. $Bi(C_7H_5O_2)_3$. *Bismuthi Benzoas.*—It is a white powder, insoluble in water, and was originally proposed by P. Vigier as a substitute for the bismuth salicylate; it may be made by double decomposition between bismuth nitrate and sodium benzoate; like the salicylate, it is decomposed in the alimentary canal, benzoic acid being set free. It contains about 65 per cent. of bismuth, and may be given as an intestinal antiseptic in *diarrheas*, in *doses* of from eight to fifteen grains (0.5–1.0 Gm.) four to six times a day. It has been commended by Finger as a substitute for iodoform.

Bismuth Borate.—*Bismuthi Boras*, $BiBO_3$, is a grayish-white powder which has been used as an intestinal antiseptic in *doses* of from seven to fifteen grains (0.45–1.0 Gm.).

Bismuth Borophenate.—*Bismuthi Borophenas, Markasol*, has been recommended as a slightly astringent absorbent powder, to be used in the same way and for the same purposes as iodoform. It is free from odor, and is alleged to be locally antiseptic.

Bismuth-Cerium Salicylate is a reddish-white powder, insoluble in water and alcohol. This salt has been highly commended in *diarrhea, enteritis,* and *dysentery* by Salaya. *Dose*, ten grains (0.65 Gm.). With ferric salts it gives a violet color and is decomposed by acids and acid salts.

Bismuth Chrysophanate. *Bismuthi Chrysophanas. Dermol. Bismuthum Chrysophanicum.* $Bi(C_{15}H_9O_4)\,2Bi_2O_3$.—This is a yellow, amorphous, insoluble powder, which has been used in the treatment of various diseases of the skin.

Bismuth Citrate. *Bismuthi Citras. U. S. VIII. Bismuthi Citricum, Citrate de Bismuth*, Fr. *Wismut-citrat, Citronensaures Wismutoxyd*, G. $BiC_6H_5O_7$.—This salt which was formerly official may be prepared as follows: "Bismuth Subnitrate, *one hundred grammes* [or 3 ounces av., 231 grains]; Citric Acid, *seventy-five grammes* [or 2 ounces av., 282 grains]; Distilled Water, a *sufficient quantity*. Mix the Bismuth Subnitrate and the Citric Acid with *four hundred milliliters* [or 13½ fluidounces] of Distilled Water, and heat on a bath of boiling water, with frequent stirring, until a drop of the mixture yields a clear solution with ammonia water. Then add *five thousand milliliters* [about 11 pints] of Distilled Water, allow the suspended matter to deposit, wash the precipitate, first by decantation, and afterwards on a strainer, with Distilled Water, until the washings are tasteless, and dry the residue at a gentle heat." *U. S. VIII.* Bismuth citrate is formed; the completion of the process is known by the precipitate yielding a clear solution with ammonia water.

It is a white, amorphous or micro-crystalline powder, odorless and tasteless. Insoluble in water or alcohol, but soluble in ammonia water, and in solutions of alkali citrates. See *U. S. D.*, 19th ed., p. 237. A combination of bismuth citrate and ferric citrate (*Bismuthi et Ferri Citras*) corresponding to 21 per cent. bismuth and 9 per cent. of iron is marketed as *bismuth and iron citrate (soluble)* (*N. N. R.*, 1917). It occurs in yellowish-green scales and is readily soluble in water. It combines the therapeutic properties of its constituents and is intended for *dyspepsia* associated with *anemia*. *Dose*, five to ten grains (0.32–0.65 Gm.). The same manufacturers have also brought out a similar combination of lithium and bismuth citrate (*N. N. R.*, 1917) in soluble, colorless scales. It corresponds to 40 to 45 per cent. bismuth and 2.5 to 3 per cent. of lithium. It is incompatible with strongly alcoholic liquids, mineral acids and with some salts of heavy metals. It is recommended for *gouty dyspepsia* and *intestinal catarrh* in *doses* for adults of from five to fifteen grains (0.3–1.0 Gm.).

Bismuth Disalicylate.—Under the name of *gastrosan* appears in commerce a white powder insoluble in cold water and alcohol which is asserted to be a disalicylate of bismuth. In hot water one molecule of the salicylic acid is split off, leaving behind the ordinary bismuth subsalicylate. It is claimed for this preparation that it is superior in intestinal fermentation to other preparations of bismuth, because the second molecule of salicylic acid is liberated in the bowel and exercise a powerful antiseptic influence. Witthauer has employed it with beneficial effects in *diarrhea* and in *gastric disturbances*. (*Ph. Centralh.*, 1909, p. 716.) It is marketed in the form of lozenges each containing twelve grains (0.75 Gm.) of the salt and one or two lozenges may be given three times a day.

Bismuth Ditannate. *Bismuth Tannate, Bismuth Bi-tannate. N. N. R.* 1917.—Under the trade name of *Tannismuth* this salt has been introduced into medicine. It is a light yellow powder, insoluble in water, and represents from 17 per cent. to 21 per cent. of bismuth, one atom of bismuth being combined with two molecules of tannic acid. It has been used in the treatment of *intestinal catarrh*, and by some is believed to be more astringent than the other insoluble salts of bismuth on the supposition that one of the tannic acid molecules will be split off in the intestinal tract. The *dose* is five to thirty grains (0.3–2.0 Gm.).

Bismuth Dithiosalicylate. *Bismuthi Dithiosalicylas. Thioform.* $(S.C_6H_3(OH)COO.BiO_2 + Bi_2O_3 + 2H_2O$.—This is a yellowish-gray, odorless and tasteless powder, insoluble in water, alcohol, or ether, containing 72 per cent. bismuth oxide. It has been used externally as a dusting powder in *skin diseases* and in surgery, and probably acts precisely as does dermatol. It has been employed upon the eye to a considerable extent and is not irritant. Internally it has been given in *diarrhea* as an intestinal antiseptic in *doses* of five

grains (0.32 Gm.) three or four times a day in capsules.

Bismuth Formic Iodide.—This is a mixture of formaldehyde-gelatin, thymol iodide, and bismuth sub-iodide in the form of a yellowish powder and used as an antiseptic dusting powder applied to *ulcers* and *sores* that require stimulant action.

Bismuth Iodo-oxyquinoline-sulphonate. *Bismuthi Loretinas. Loretin Bismuth.*—This compound has been used in the *dose* of eight grains (0.5 Gm.) every four hours in the treatment of *tubercular* and other obstinate *diarrheas*, and as a local application in powder form to *epithelioma, syphilitic* and other forms of infected *ulcers*. The 10 per cent. ointment made with lanolin has been recommended in *eczema* and *psoriasis*.

Bismuth Lactate. *Bismuthi Lactas.* $C_3H_4O_3Bi$ $HC_3H_4O_3$.—This salt may be made as follows: Take of bismuth subnitrate, *sixty-one parts;* ammonia water, *fifty parts;* lactic acid, *fifty-five parts;* distilled water, a *sufficient quantity*. Mix the bismuth subnitrate, in a flask, with the ammonia water previously diluted with *seventy-five parts* of distilled water. Let the mixture stand for one hour, pour off the supernatant liquid, and wash the residue thoroughly with distilled water. To the moist residue add the lactic acid, and evaporate the mixture to dryness on the water bath. The product is a white powder, slightly soluble in water and insoluble in alcohol. It may be used in *diarrhea* in *doses* of one to two grains (0.065–0.13 Gm.).

Bismuth Metacresolate. *Bismuthi metacresolas.*—A pale gray or white powder, odorless and tasteless, insoluble in water and alcohol. It is used as an intestinal antiseptic and also as an antiseptic dusting-powder, to take the place of iodoform.

Bismuth Nucleinate.—*Bismuth paranucleinate* or *parabismuth* is a pale yellow, odorless, insoluble powder, containing about 50 per cent. of bismuth. It has been employed in the treatment of *enteritis* of both the acute and chronic types. *Dose*, fifteen to thirty grains (1–2 Gm.).

Bismuth Oleate. *Bismuthi Oleas.* $Bi(C_{17}H_{33}CO_2)_3$.—A compound resulting from the reaction between sodium oleate and bismuth trinitrate. It forms an insoluble powder or mass and is used as an emollient and astringent.

Bismuth Oxide. *Br.* 1898. *Bismuthi Oxidum. Bismuth Trioxide. Bismuthum Oxydatum, Oxydum Bismuthicum. Oxyde de Bismuth*, Fr. *Wismutoxyd*, G.—"Bismuth Oxide ($Bi_2O_3 = 464.00$), may be prepared by boiling bismuth oxynitrate with solution of sodium hydroxide." *Br.*, 1898. It is decomposed by solution of sodium hydroxide in this process, bismuth hydroxide being formed, which is precipitated, while sodium nitrate remains in solution.

$$2BiNO_4.H_2O + 2NaOH = Bi_2O(OH) \text{ (or } Bi_2O_3.3H_2O) + 2NaNO_3$$

At the temperature of 100° C. (212° F.) the bismuth hydroxide is decomposed, water is liberated, and the anhydrous oxide is left. Bismuth oxide is a powder of a dull lemon-yellow color, insoluble in water, but soluble without effervescence in nitric acid, mixed with half its volume of water. The British Pharmacopœia. 1898. describes it as "a slightly brownish-yellow powder. It should answer to the general characters and tests enumerated under 'Bismuth Oxycarbonate.' Each gramme should yield 1.1 grammes of bismuth sulphide. Heated to incipient redness it is scarcely diminished in weight (absence of bismuth oxycarbonate, bismuth oxynitrate, and moisture)." *Br.*, 1898. It resembles bismuth subnitrate in its medicinal properties, and may be administered in *doses* of from ten to thirty grains (0.65–2.0 Gm.).

Bismuth Oxybromide. *Bismuthi Oxybromidum. Wismutoxybromid*, G. BiOBr.—This is an impalpable yellow to a brown powder, used internally in gastric affections.

Bismuth Oxychloride. *Bismuthi Oxychloridum seu Subchloridum. Bismuth Subchloride. Bismuthyl Chloride. Oxychlorure de bismuth*, Fr. *Wismutoxychlorid*, G. BiOCl.—Made by slowly pouring a solution of bismuth trinitrate, in diluted nitric acid, into a solution of sodium chloride, collecting the white precipitate, washing and drying. It is sometimes known as *pearl white*, and in France as *blanc de fard*. Bismuth oxychloride is insoluble in water, soluble in acids. and is used for the same purposes as bismuth subnitrate and also for cosmetic purposes.

Bismuth Oxyiodide. *Bismuthi Oxyiodidum.* BiOI. *Bismuth Subiodide.*—For F. X. Moerk's process for the preparation of this salt, see *U. S. D.*, 19th ed., p. 1416. The oxyiodide has a light yellowish-red color, and contains no water of crystallization. (*A. J. P.*, 1887, 273.) In 1877 the bismuth oxyiodide was recommended as a local antiseptic and substitute for iodoform, by A. Sidney Reynolds. It has been used to a considerable extent with success in the Philadelphia Hospital, but its high price interferes with its general adoption. It has also been given internally in *gastric ulcer* and other gastric affections for which bismuth is usually employed. The *dose* is from five to ten grains (0.32–0.65 Gm.).

Bismuth Oxyiodogallate. *Bismuth Iodsubgallate. Airol. Airoform. N. N. R.* 1917. $C_6H_2(OH)_3COO(BiOHI)$.—This is a basic combination of bismuth, oxygen, iodine, and gallic acid, containing in 100 parts 44.6 parts of bismuth trioxide and 24.3 parts of iodine. It is prepared by heating molecular quantities of bismuth subgallate and hydriodic acid or bismuth oxyiodide and gallic acid in the presence of water until a grayish-green product results which is collected, washed and dried. It is a grayish-green odorless and tasteless powder insoluble in alcohol, ether, chloroform and olive oil, slightly soluble in glycerin. It is decomposed upon contact with water or aqueous solutions, slowly in the cold, more rapidly by heat. Airol is incompatible with water, diluted acids, dilute alkalies, etc., and it should be kept dry, as moist air causes liberation of iodine.

When airol is brought in contact with surgical secretions it becomes red from the liberation of iodine. According to the researches of Carl S. Haegler (Bruns, *B. k. Ch.*, xv, 1896), it is about as feeble an antiseptic as is iodoform, but as in the case of iodoform the substances liberated by its decomposition in wounds are actively germicidal. Von Herrenschwand (*Archiv. fur Ophthalm.*, 1913, lxxxii) finds, however, that one part of airol in a thousand is capable of killing gonococci and that one in ten thousand completely inhibits their growth. It has been largely used as a local remedy in all cases for which iodoform has been employed, having the superiority over that substance of being nearly free from odor. It does not irritate, but rapidly desiccates ulcerated surfaces. In the only case of poisoning by it which we have found recorded, symptoms of bismuth poisoning followed the injection into the

cavity of an abscess of nine and a half fluidrachms (35 mils) of its 10 per cent. glycerin solution (Nemmer).

Injected into the peritoneal cavities of the lower animals in the dose of from one to two grammes per kilo, airol causes colonic convulsions, with coma, nephritis, and fatty degeneration of the liver.

It may be used as a powder or as a 10 to 20 per cent. salve, which should be prepared with lard or vaseline free from water, since with water, airol undergoes rapid decomposition. Airol is used as an antiseptic dusting powder in the treatment of *wounds*. It has been found of service as a local remedy in various *catarrhs*, as *vaginitis* or *rhinitis*. Bernheimer has used airol successfully in the treatment of gonorrheal *ophthalmia*. The eye is first carefully cleansed and the everted lids are then dusted with the finely powdered drug. This procedure is to be repeated several times a day. A 10 per cent. glycerin emulsion has been recommended as an injection into *tubercular abscess* cavities.

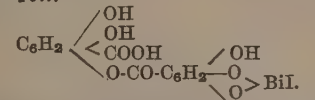
Bruns' Paste, which has been much used in various skin diseases and ulcerations, is made according to the following formula: Airol, *one part;* Mucilage, *two parts;* Glycerin, *two parts;* Argilla Alba (Kaolin), *sufficient to make a soft paste.* If the paste becomes too dry, use glycerin; if it be too soft, kaolin may be added. No metal instruments should be employed in preparing the paste, since many metals liberate iodine from airol. For the same reason, no water, only glycerin, should be used in the preparation. The paste is preserved in well-stoppered glass or porcelain jars, which are to be kept closed.

Bismuth Oxyiodo-methyl-gallol. *Bismuthi Oxyiodo-methylgallolum. Iodo-gallicin.* $C_6H_2COOCH_3(OH)_2O.BiOH.I$.—Made by acting upon gallicin (methyl gallate) with bismuth oxyiodide. It is in the form of a light, amorphous, dark gray powder, insoluble in ordinary solvents and containing 23.6 per cent. of iodine and 38.4 per cent. of bismuth.

It is used as a siccative and antiseptic powder to replace iodoform.

Bismuth Oxyiodo-pyrogallate. *Bismuthi Oxyiodo-pyrogallas.* $C_6H_2(OH)_2.O.Bi(OH)I$.—Made by digesting bismuth oxyiodide with pyrogallic acid or by precipitating a solution of potassium iodide and pyrogallic acid with bismuth nitrate in acetic acid. A fine, amorphous, yellowish-red powder, permanent in light and air. It is recommended as a surgical antiseptic powder.

Bismuth Oxyiodo-tannate. *Bismuthi Oxyiodotannas. Ibit.*



Bismuth oxyiodo-tannate is a greenish-gray, odorless, tasteless powder, becoming brownish on exposure, insoluble in water, and has been suggested as a surgical substitute for iodoform.

Bismuth Peptonate. *Bismuthi Peptonas.*—Prepared by adding a solution of 80 parts of dried peptone to 20 parts of bismuth and ammonium citrate, dissolved in a small quantity of water, and drying at a low temperature. A grayish-brown powder containing from 7 to 8 per cent. of bismuth. It is used in *dyspepsia* and *gastralgia* in *doses* of from fifteen to sixty grains (1.0–3.9 Gm.).

Bismuth Permanganate. $Bi(MnO_4)_3$.—A black bulky powder, soluble in dilute acids, used as an external antiseptic in the form of a dusting powder for *wounds* and *ulcers*, combining the properties of permanganates and bismuth compounds.

Bismuth Phenolate. *Bismuthi Phenolas. Bismuth Carbolate. Phenol-Wismut,* G. $C_6H_5O.Bi(OH)_2$.—Made by a reaction between solutions of bismuth trinitrate and sodium phenolate. A gray, insoluble, inodorous powder, used as an intestinal antiseptic, in *doses* of from eight to fifteen grains (0.5–1.0 Gm.), also as an antiseptic dusting-powder.

Bismuth Phosphate, Soluble. $BiPO_4$.—*Bismuthi Phosphas Solubilis,* which is prepared by the melting together of bismuth, sodium hydroxide, and phosphoric acid, is a white powder easily soluble in water, precipitated by alkalies, acids, or heat, and undergoing spontaneous decomposition when in concentrated solution. It contains 20 per cent. of bismuth, and has been used as an intestinal antiseptic in *choleraic* and other acute *diarrheas* in the *dose* of from three to eight grains (0.2–0.5 Gm.) three times a day.

Bismuth Pyrogallate. *Bismuthi Pyrogallas. Helcosol, Helsosal,* $C_6H_3(OH)_2OBiOH$.—It is a yellowish-green amorphous powder, insoluble in water and alcohol, soluble in acid and alkaline solutions and in the gastro-intestinal juices. According to von Heyden, it represents about 60 per cent. of bismuth oxide. It is said to be non-poisonous, and to be a valuable intestinal antiseptic; if, however, pyrogallic acid should be liberated in the alimentary canal, it might produce disagreeable effects, and the remedy seems to us dangerous. It is asserted that *acids* liberate pyrogallic acid from this combination, thus contradicting the previous statement. It is incompatible with strong alkalies and alkaline sulphur compounds.

Bismuth Resorcinate. *Bismuthi Resorcinas. Resorcin-Wismut,* G. $[(C_6H_4O_2)_3Bi_2]_3 + Bi_2O_3$.—Prepared by adding a solution of bismuth trinitrate to a solution of resorcinol in an excess of alkali. A yellowish-brown powder containing about 40 per cent. of Bi_2O_3. It is used in *chronic* and *acute catarrh* of the stomach. *Dose,* two to eight grains (0.12–0.5 Gm.).

Bismuth Subbenzoate, or *basic bismuth benzoate,* is official in the French Codex, $Bi(C_7H_5O_2)_3Bi(OH)_3$.—It is a white powder containing 60 to 70 per cent. of Bi_2O_3. It is insoluble in water and used externally as a dry dressing in *syphilitic ulcers.*

Bismuth Sulphite. *Bismuthi Sulphis,* $Bi_2(SO_3)_3$, is made by reacting on normal bismuth nitrate with sodium sulphite. It is used as an antiseptic and anthelmintic.

Bismuth Valerate. *Bismuthi Valeras. Valérianate de Bismuth,* Fr. *Wismutvalerianat,* G. $Bi(C_5H_9O_2)_32Bi(OH)_3$.—This salt is formed by double decomposition between solutions of bismuth trinitrate and sodium valerate. Bismuth valerate precipitates as a white powder, which is washed with water, and dried with a gentle heat. It has been recommended by Righini in *neuralgia,* and in *gastrodynia.* The *dose* is from half a grain to two grains (0.032–0.13 Gm.), repeated several times a day, and given in the form of pill.

Bismuthol. *Bismuthal.*—This substance, which is probably a mixture of the bismuth phosphate and sodium salicylate, is a white, crystalline, odorless powder, soluble in water. It has been commended by Radlauer as an antiseptic in the

treatment of *wounds* and inflammations of the mucous membrane. It has been especially recommended for excessive *sweating of the feet.*

Bismutose.—This substance is said to be an albuminous compound containing 22 per cent. of bismuth, and 66 per cent. of albumin. It is a tasteless, white powder which gradually acquires, under the influence of light, a slaty-gray color. It is insoluble in water and most other solvents; dilute acids partly dissolve it when warmed. With dilute alkaline solution it forms rapidly, especially when heated, an opalescent fluid from which it is precipitated by alcohol. It is affirmed to be non-poisonous. It has been highly praised by Laquer (*Ther. Geg.*, 1901) as a remedy, specially for children, in all those forms of *gastric* and *intestinal irritation* or *ulceration* for which bismuth has been employed. The *dose* for infants is fifteen to thirty grains (1–2 Gm.), for children a drachm (3.9 Gm.), and for adults larger quantities. It is also employed as a dusting powder in the treatment of *burns* and *intertrigo* as an absorbent.

Bistort. *Snakeweed. Bistorte, Couleuvrine,* Fr. *Weissenknöterich, Natterwurz,* G.—This is the rhizome of *Polygonum Bistorta,* L. (Fam. *Polygonaceæ*), a perennial herbaceous plant, growing in Europe and the north of Asia. The rhizome is cylindrical, somewhat flattened, about 1 to 2 cm. in thickness, marked with annular or transverse wrinkles, furnished with numerous rootlets, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. Externally it is dark purplish or blackish-brown. The fracture is nearly smooth, reddish or purple, the taste being astringent. It contains much tannin, some gallic acid and gum, and a large proportion of starch. H. K. Bowman found 21 per cent. of tannin in bistort root. (*A. J. P.*, 1869, 193.) Its medicinal properties are like those of kino, but it is less efficient. It may be employed in powder, decoction, or extract. The *dose* of the powder is twenty or thirty grains (1.3–2.0 Gm.).

Besides the bistort, some other plants belonging to the genus *Polygonum* have been used as medicines. Among these are *P. aviculare,* L., or *knot weed,* a mild astringent, formerly employed as a vulnerary and styptic; *P. Persicaria,* L., or *lady's thumb,* of a feebly astringent saline taste, and at one time considered antiseptic; and *P. Hydropiper,* L., common *smartweed,* or *water-pepper,* the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic, and have been used with asserted success in *amenorrhea* and other *uterine disorders.* Its irritant and also medicinal properties are due to an acid, *polygonic acid,* discovered by C. J. Rademaker. *Polygonum Hydropiper* has been used by Krawkoff (*Russki Vratch,* 1912) in the treatment of *internal hemorrhages,* especially of the uterus. He administered from thirty to forty drops of a fluidextract of the leaves. (*A. J. P.*, xliii, 490.) The *water-pepper* or *smartweed* of this country—*P. acre* H. B. K.—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic *ulcers,* and internally in *gravel.* B. Woodward found that the dried plant contains 18 per cent. of tannin, and used a saturated tincture with great advantage in *diarrhea* and *dysentery,* in *doses* of from twenty to sixty minims (1.3–3.75 mils). Aughey finds that *P. amphibium,* L., is readily cultivated, with a yield of from three to six tons to the acre, that the roots contain 21.75 per cent., the stems 17.1 per cent. of tannic acid, and urges the growth of it for tanning purposes. (*N. R.*, 1876, 75.)

Fagopyrum esculentum Moench is common *buckwheat.* The leaves of this plant have been found by Ed. Schunck to contain a crystallizable coloring principle, identical with the *rutin* or *rutic acid* previously discovered by Weiss in the leaves of the common rue, and probably, with the *ilixanthin* of Moldenhaus, existing in the leaves of *Ilex Aquifolium* L., or the common holly. Buckwheat leaves yielded to Schunck somewhat more than one part of rutin in a thousand. (*Chem. Gaz.*, No. 399, 201.)

From *P. cuspidatum* L. has been separated a glucoside, *polygonin,* and also *emodin.* (*P. J.*, Feb., 1896.) The bark of the rhizome has been recommended by Goris and Crète (*Bull. Sci. Pharmacol.*, 1907) as a laxative. The leaves of the *P. dumetorium* are, according to Tunmann (*Ph. Centralh.*, 1906), also practically useful as a laxative.

Various species of the genus *Polygonum* are used for the production of dye-stuffs; thus, indigo is obtained largely in China, Japan, and in some parts of Russia, from the leaves of *P. tinctorium* Ait., and is said also to be yielded by those of *P. aviculare* and *P. barbatum,* L.; while in India, China, and Japan the roots of the *P. cuspidatum* are employed for making a yellow dye. (*J. Chem. S.*, Dec., 1895.)

Bituminol. *Ammonium Sulpho-Bituminolate.*—This substance, manufactured by a German firm, is used as a substitute for ichthyol.

Blenal. *Santalol Carbonate.*—Blenal is the carbonic acid ester of santalol. It is a yellowish, oily fluid, soluble in alcohol and ether, but not in water. It is almost free from taste or odor, and represents 94 per cent. of santal oil. Blenal may be used for all the purposes for which santal is serviceable. It has, however, been employed chiefly as an internal remedy in the treatment of *gonorrhea.* The *dose* is fifteen drops three times a day, preferably given stirred up in milk, or it may be administered enclosed in capsules each of which may contain half of this quantity.

Blennostasine. *Cinchonidine dihydrobromide.*—This forms yellowish, deliquescent crystals and is freely soluble in water. W. F. Campbell (*N. Y. M. J.*, lxiv, 1896) asserted that it is a powerful sedative to the brain and spinal cord, and that in *doses* of from one to four grains (0.065–0.26 Gm.) every hour it is a valuable remedy in nasal and laryngeal hyperesthesia. It has been especially recommended to check excessive secretions in *acute coryza.*

Blepharis. *Blepharis capensis.* (Fam. *Acanthaceæ.*)—This plant is said to be physiologically very active and useful in the treatment of *anthrax.* (*P. J.*, lx, p. 140.)

Blood of Bullocks.—As long ago as 1852, Samuel Jackson, of Philadelphia, employed as a tonic the blood of bullocks carefully dried *in vacuo,* giving from five to ten grains (0.32–0.65 Gm.) of it as a *dose.* At one time it was used considerably in Europe, and even drinking fresh bullock's blood was at one time in fashion. *Bioferrin* is a liquid preparation of hemoglobin. It is prepared from carefully examined tubercle-free ox blood, by a process which renders it sterile and palatable. It is a brownish-red fluid with a peculiar, though not unpleasant taste and odor, and containing for its conservation 2.5 per cent. alcohol and 20 per cent. glycerin. It is used in the treatment of

anemic children. Under the name of *Sanguis Bovinus Exsiccatus*, F. E. Stewart introduced defibrinated dried bullock's blood, claiming for it that, by the simple addition of water, bullock's blood can be reproduced minus a small quantity of fibrin. There is no reason for believing that dried blood is more valuable than the more usual ferruginous tonics, if indeed it be of equal value.

Apparently by increasing the fibrinogen of the blood, foreign blood serum accelerates coagulation and has therefore been used in the treatment of *internal hemorrhages*. There are at least two derivatives of blood serum upon the market known respectively as *coagulose* and *coagulin*. Coagulose appears to be merely the desiccated sterilized serum of horse blood. It is marketed in sealed bulbs each containing one grain (0.65 Gm.) of the powder, which is equivalent to 10 mils of blood serum. It is administered by dissolving this powder in sterile water and injecting the resulting solution hypodermically. The injection may be repeated every two or three hours or less frequently as the case requires. There is, however, some objection to the use of horse serum on the possibility of anaphylactic reactions, and Curtis (*J. A. M. A.*, 1915, lxiv, p. 332) has found the hypodermic injection of whole human blood to be equally efficacious. He administered subcutaneously from ten to twenty mils. Coagulin was introduced by Kocher and Fonio (*Korrespondenzbl. f. Schweiz. Aerzte*, 1913) and is obtained by the action of the ferment thrombozyme on blood serum. It is used especially in the treatment of primary or secondary *hemorrhages* and of *wounds*.

Blue Flag. *N. F. IV.* (*U. S. P.* 1890.) *Iris Versicolor.*—"The dried rhizome of *Iris versicolor* Linné (Fam. *Iridaceæ*), without the presence of more than 5 per cent. of the roots and leaf bases." *N. F.* In all the species belonging to this genus, so far examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, *Iris fœtidissima* L., *I. florentina* L., *I. germanica* L., *I. pseudoacorus* L., and *I. tuberosa* L. have at various times been admitted into use, and the unpeeled roots of *I. germanica* are still sold in the Indian bazaars under the name of *Irisia*. *Iris versicolor* L., or blue flag, is found in all parts of the United States, flourishing in low wet places in meadows. The flowers afford a fine blue infusion, which serves as a test for acids and alkalies. The recent root is without odor, and has a nauseous, acrid taste, which is imparted to water by decoction, and still more perfectly to alcohol, the acrimony as well as medicinal activity is impaired by age. If cut, when fresh, into slices, dried at the temperature of about 37.8 ° C. (100° F.), then powdered and kept in bottles excluded from the air, the root retains its virtues unimpaired for a considerable time (Andrews). It is described as follows in the National Formulary IV:

"Rhizome frequently branched, up to 10 cm. in length and 2 cm. in thickness, usually cut into longitudinal pieces; outer surface grayish-brown to purplish-brown, somewhat annulate, the upper surface with markings of leaf bases, the lower with numerous root scars and remnants; fracture short, the broken surface pale purplish-brown and exhibiting a central stele with whitish fibro-vascular bundles distributed throughout, a distinct endodermis, and cortex. Odor slight, not distinctive; taste acrid, nauseous. The powder is light purplish-brown and, when examined under the microscope, exhibits numerous resin cells filled with yellow to brown resin; starch grains few, or, in some specimens, abundant, simple, or two- to four-compound, the simple grains being spherical or elliptical, up to 0.022 mm. in diameter; calcium oxalate in prisms, up to 0.35 mm. in length; tracheæ with spiral or reticulate markings or with bordered pores; sclerenchymatous fibers few, lignified and with oblique pores. Blue flag yields not more than 7 per cent. of ash." *N. F.*

D. W. Cressler found in this plant starch, gum, tannin, sugar, and acid resin, fixed oil, and indications of an alkaloid. (*A. J. P.*, 1881, p. 602.)

Blue flag is a cathartic and emetic, said to have been used by the Southern Indians, and may be given in *doses* of from ten to twenty grains (0.65–1.3 Gm.). *Iridin*, or *irisin*, of the eclectics, is an oleoresin obtained by precipitating a tincture of the root with water, and mixing the precipitate with an equal weight of some absorbent powder. Wm. E. Jenks (*A. J. P.*, 1881, p. 601) prepares the *oleoresin of iris* by exhausting the root with alcohol, sp. gr. 0.835, and distilling off the alcohol. (See also a paper on the constituents of the oleoresin by W. L. Cliffe, *A. J. P.*, 1884, p. 616.) The so-called irisin is undoubtedly purgative and is generally believed to have a very decided action upon the liver. Power and Salvay (*A. J. P.*, 1911, 14) isolated *isophthalic acid*, $C_6H_4(CO_2H)_2$. It may be given in pill in the *dose* of from three to four grains (0.20–0.26 Gm.).

The Pharmacopœia formerly recognized a solid *extract* (*Extractum Iridis*), made by the following process: "Iris, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*. Moisten the powder with *four hundred mils* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until *three thousand mils* [or 101 fluidounces, 3½ fluidrachms] of tincture are obtained, or the Iris is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*, 1890. The *dose* of the extract of iris is one to two grains (0.065–0.13 Gm.).

A fluidextract is official in the N. F. (see Part III).

Blumea. *Blumea lacera* DC. (Fam. *Compositæ*.)—From this plant, which is used in India as an insect powder, Dymock has obtained a light yellow volatile oil. It has a sp. gr. of 0.9144 at 26.7° C. (80° F.), and an extraordinary rotating power, 1 mm. turning the ray 66° to the left.

Bocconia.—It is probable that various species of this papaveraceous genus have active medicinal properties. *B. arborea* Watson, of Mexico, has been found by Elliott to contain two alkaloids, one of which is probably *sanguinarine;* and the leaves of other species are used in South America as an abortifacient and purgative. (See Rusby, *Bull. Pharm.*, 1891.) Murrill and Schlotterbeck (*Proc. A. Ph. A.*, 1900, p. 128) examined all parts of *Bocconia cordata*, and isolated protopine, homochelidonine, chelerythrine and sanguinarine.

Boldo. *N. F. IV. Boldo Leaves.*—It is described by the N. F. as "the leaves of *Boldu Boldus* (Molina) Lyons (Fam. *Monimiaceæ*), without the presence of more than 2 per cent. of stems or other foreign matter. Broadly ovate or oval,

from 3 to 7 cm. in length and from 1 to 4 cm. in breadth, the base varying from rounded to very slightly indented, the summit rounded or slightly notched, the margin entire and sharply revolute; thick, coriaceous, rigid and brittle; from pale-green to brownish-green, papillose, roughened on both surfaces, the principal veins coarsely reticulate, impressed above, sharply prominent underneath; the petiole stout and rigid, from 1 to 5 mm. in length, reticulate. Odor peculiar; when crushed very strong, disagreeable, and somewhat like that of oil of chenopodium; taste bitter, warm and pungent, camphoraceous and slightly terebinthinate. Under the microscope a transverse section shows a well-marked hypodermis from which develop papilla-like excrescences, each crowned with a group of radiating, one-celled, thick-walled hairs; on the lower surface stomata numerous and hairs somewhat smaller, mesophyll with numerous oil secretion cells. Boldo yields not more than 10 per cent. of ash." This plant is an evergreen shrub, frequenting the meadows of the Andes in Chili, where its yellowish-green fruit is eaten, its bark used in tanning, and its wood is employed in charcoal making. The leaves contain an aromatic, volatile oil, of which they yield, on distillation, about 2 per cent. The oil boils between 175° and 250° C. (347° and 482° F.) and gives a green coloration with ferric chloride; it contains terpene and oxygenated bodies which have not as yet been investigated. For chemistry of the *Oil of Boldo*, see *Schim. Rep.*, Oct., 1907, p. 19. They have found that the oil is chemically related to the Oil of Chenopodium. A peculiar alkaloid, *boldine*, has been found in them by Bourgoin and Verne (*J. P. C.*, 4e sér., xvi, 191), and a glucoside, *boldoglucin*, $C_{30}H_{52}O_8$, a thick syrupy liquid, by P. Chapoteaut. (*C. R. A. S.*, xcviii, 1052.) According to Sigismond Pascaletti (*Terapia Moderna*, 1891), boldine when injected hypodermically paralyzes both the motor and sensory nerves, and also attacks the muscle fibers. When given internally in toxic dose it produces great excitement, with exaggeration of the reflexes and of the respiratory movements, increased diuresis, cramps, disorder of coördination, convulsions, and finally death from centric respiratory paralysis, the heart continuing to beat long after the arrest of respiration, finally stopping in diastole. Boldine has in recent years come into wide use in veterinary medicine as a remedy for *jaundice*. It has also been used in man in the treatment of hepatic affections, given in *doses* of one one-hundredth to one-twentieth of a grain (0.0006–0.003 Gm.) in conjunction with calomel. Boldoglucin is said to act on the lower animals as a narcotic, and has been given by Réne Juranviller in *doses* of one to three grains (0.06–0.2 Gm.) in diseases of the liver. Fifteen minims (0.9 mil) of the oil of boldo cause in man some warmth in the epigastrium; thirty minims (1.8 mils), much gastric irritation, with pain and vomiting, and passage of urine smelling strongly of the oil. Dujardin-Beaumetz finds the oil useful in *genito-urinary inflammations* in *doses* of five drops (0.25 mil) (*B. G. T.*, March, 1875), in diseases of which character the drug has long been employed in South America. (*Ibid.*, lxxxvi, 165.) In France boldo has been employed as a tonic in *chronic hepatic torpor* and in *hepatitis*, and Fedeli (*Il Policlinico*, 1907) reports favorable results in the treatment of *cholelithiasis*. Eight minims (0.5 mil) of a 20 per cent. tincture or four minims (0.25 mil) of the N. F. fluidextract may be considered as the commencing *dose*, increased *pro re nata*. Large doses are apt to vomit and purge.

According to A. T. De Rochebrune (*Toxicol. Africaine*, i, 1897), the tree *Monimia rotundifolia*, of Australia, contains an abundant volatile oil, an alkaloid, and a glucoside, which are very similar to, if they are not identical with, those obtained from the *Boldo*, and may be substituted for the latter in therapeutics.

Bole Armenian. *Bolus Armeniæ. Bolus Rubra. Argilla Ferruginea.*—The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in color or in place of origin. Such were the *Armenian*, *Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terræ sigillatæ*. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared by trituration and elutriation, from certain native earths existing in different parts of Europe. It is in pieces of various sizes, reddish, soft, and unctuous, adhesive to the tongue, and capable of forming a paste with water. It consists chiefly of a hydrated aluminum silicate with ferric hydrate. The boles were formerly employed as absorbents and astringents in *acidity of the stomach* and in *relaxed bowels*. Bole Armenian is used chiefly as a coloring ingredient in tooth-powders.

Boliformin.—A condensation product of formalin with an aluminum salt is exploited under this name, as an antiseptic dusting powder, mainly used in veterinary practice.

Bonduc Seeds.—These are seeds derived from several species of the genus *Cæsalpinia* (Fam. *Leguminosæ*), which are used in India as febrifuges, tonics, and antiperiodics. Heckel and Schlagdenhauffen have discovered in them a bitter principle (*C. R. A. S.*, ciii, 89), probably identical with that previously isolated by Flückiger. (*Pharmacographia*, 2d ed., 212.)

Bone. *Os*, Lat., Fr. *Knochen-Asche*, G. *Ossa*, It. *Huesos*, Sp.—Under the name of *Os Ustum*, or *Bone ash*, the Br. Pharmacopœia formerly recognized "the residue of Bones, which have been burned to a white ash in contact with air. Bone ash consists principally of phosphate of calcium, mixed with about 10 per cent. of carbonate of calcium and a little calcium fluoride, silica, and magnesium phosphate." When bones are subjected to destructive distillation, in *closed* vessels, they are decomposed without alteration of shape, lose about three-sevenths of their weight, become brittle, and are converted into a black substance, containing the earthy salts of the bone, and constituting the species of animal charcoal called *bone black*. (See *Carbo Animalis*.) The portions which distil over consist of the usual ammoniacal products derived from animal matter, but are especially rich in nitrogenous bases of the pyridine and quinoline series. (See *Ammonii Chloridum*.)

When calcined in open vessels, bones are converted into a white friable substance consisting of the incombustible part, and commonly called *bone earth*, or *bone ash;* and a similar residue is obtained by calcining horns, and is termed *Cornu Ustum*. When bones are treated with boiling water, a small portion of the gelatinous matter is dissolved; but when acted on by water in a Papin's digester, the whole of it is taken up and the earthy salts, deprived of their cement, crumble

into powder, and become diffused through the solution. When acted on by diluted hydrochloric acid, the earthy salts are dissolved, and the bone softens without losing its shape and becomes semi-transparent and flexible. The portion remaining unattacked by the acid is the gelatinous tissue, which may be converted into gelatin by boiling with water. The hoof bones of the ox, boiled with water, furnish a peculiar oil, called *neat's-foot oil.*

The bones of different animals, and of the same animal at different ages, vary somewhat in composition. Dry ox bones consist of bone gelatin (cartilage of bone) 33.3, calcium bone phosphate with a little calcium fluoride 57.35, calcium carbonate 3.85, magnesium phosphate 2.05, and sodium hydroxide with a very little sodium chloride 3.45. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese. According to W. Heintz, however, bones exhausted by water, so as to remove the coloring matter of blood, do not contain a trace of iron. Marchand found 1 per cent. of calcium fluoride in human bone. *Calcium bone phosphate* consists of the tribasic phosphate, $Ca_3(PO_4)_2$.

Borago. *Borago officinalis,* L. *Borage. Bourrache,* Fr. *Borasch, Boretsch,* G. (Fam. *Boraginaceæ.*)—This European annual abounds in mucilage, and the stems and leaves contain potassium nitrate with other salts. To these constituents the plant owes its feeble medicinal properties. An infusion of the leaves and flowers is employed as a demulcent, refrigerant, and gently diaphoretic drink. The expressed juice of the stems and leaves is also given in the *dose* of from two to four fluidounces (60–120 mils).

Bornyval.—This isovaleric ester of borneol, $CH_3CH(CH_3).CH_2CO.O(C_{10}H_{17})$, $C_{10}H_{17}O.C_5H_9O$, is a limpid fluid with an aromatic odor, suggesting valerian; soluble in alcohol and ether, insoluble in water; boiling under ordinary pressure, at 255° to 260° C. (491°–500° F.); sp. gr. at 20° C. (68° F.) 0.951. Polariscopic rotation: $[\alpha]_D$ 20° = 27° 40′. Bornyval has been highly lauded by a number of physicians in the same class of cases in which valerian is commonly employed, such as *nervous headache, neurasthenia, dysmenorrhea,* and the like. It has also been recommended in the treatment of various forms of *sexual disturbances,* and even in *epilepsy.* The *dose* is four to eight minims (0.25–0.5 mil) several times a day.

Under the name of *Neo bornyval, N. N. R.* 1917, the iso-valeryl-glycolic ester has been introduced. This is supposed to have the advantage over the older bornyval in that it is less easily affected by the gastric juices and therefore less liable to give rise to disturbances of the stomach. It is used for the same purposes as bornyval and appears in commerce in the form of pearls, each of which contains 0.25 Gm. (3½ gr.). Of these one to three may be given at a *dose.*

Under the trade name *Gynoval* (*N. N. R.* 1917) $CH_3CH(CH_3)CH_2COOC_{10}H_{17}$, is marketed, being the isovaleric acid ester of isoborneol. It is similar in appearance and properties to Borynval. (See also *Brovalol,* p. 1290.)

Boro-Benzoic Acid is a colorless, crystalline product with the characteristic benzoic odor and a pungent taste. It is almost insoluble in cold water and slightly soluble in warm water and alcohol. It is employed as an internal antiseptic, in *doses* of ten to twenty grains (0.6–1.3 Gm.).

Boro-Citric Acid.—A combination of the two acids, forming a white, very soluble powder. It is used in *doses* of from five to twenty grains (0.32–1.3 Gm.) as a solvent for the urates and phosphates in *urinary calculi* and *gout.*

Borogen.—This is the ethyl ester of boric acid, $B(O.C_2H_5)_3$. It is a liquid, boiling at 120° C. (248° F.), which is decomposed by water into boric acid and alcohol. It is inflammable, burning with a green flame. This substance has been suggested as a local remedy in diseases of the nasal and respiratory mucous membrane, under the belief that it is decomposed into its constituents in the throat and lungs. Borogen is used by inhalation.

Boroglyceride. *Boroglycerinum. Glyceryl-borate.*—This substance has been largely employed as a convenient form of obtaining boric acid in a soluble condition. It is made by heating boric acid and glycerin together so as to effect a combination without discoloring the product by overheating. (See *Glyceritum Boroglycerini,* page 524.) James Kennedy (*Nat. Drug.,* 1887, 46) maintained that it is a chemical compound, and not a mere mechanical mixture, as has been supposed; he gave it the formula $C_3H_5BO_3$, and expressed the reaction in its formation thus:

$$C_3H_5(OH)_3 + H_3BO_3 = C_3H_5BO_3 + 3H_2O$$

The metallic boroglycerides, such as sodium and calcium boroglyceride, are not explained, however, in this case. Aqueous solutions of boroglyceride were formerly used for preserving milk, meat, fruit juices, etc., but are now prohibited by law. Boroglyceride has been largely sold in England under the name of *glacialin.*

Borol.—This is a compound possessing the structural formula $SO_2{<}^{BO}_{KO}$ or $SO_2{<}^{BO}_{ONa}$, or, as it may be written, $BKSO_4$ or $BNaSO_4$. It occurs in irregular, colorless, odorless, vitreous fragments, soluble in five times its weight of water. According to H. Jäger, it is three times as powerful as phenol as an antiseptic, the 2 per cent. solution rapidly destroying most pathogenetic germs. It has been used internally in various germ diseases and externally in *diphtheria, gonorrhea, ozena, psoriasis,* and other surgical affections. *Dose,* from thirty to fifty minims (1.8–3.1 mils) of a 20 per cent. solution well diluted. Locally a .1 to 2 per cent. solution has been used. (*Ther. Woch.,* iv.)

Boro-Phenol is a combination of borax and phenol. It has an agreeable odor, is completely soluble in water, and can be used for all the purposes for which carbolic acid disinfectants are used.

Boro-Salicylic Acid has been introduced by Cesaris and Carcano as an antiseptic; the solution contains 4 per cent. each of boric and salicylic acids.

Borsalicyl is made by Bernegau by triturating thirty-two parts of sodium salicylate with twenty-five parts of finely powdered boric acid with a little water; the hardened mass is dried and powdered. It is used as an antiseptic. (*Ap. Ztg.,* 1894, 876.)

Bowdichia. *Bowdichia virgiliodides* H. B. K. (Fam. *Leguminosæ.*)—Under the name of *Sucupira,* the hard, yellow, very bitter bark yielded by this tree is employed in Venezuela and Brazil in *fevers* and *rheumatism.* Petit has found it in a mydriatic alkaloid. (*P. J.,* June, 1885.)

Bragantia. *Bragantia Wallichii.* (Fam. *Aristolochiaceæ.*)—The roots of this shrub of India contain an alkaloid allied to *aristolochine,* a soft

resin, a resinous acid, and a substance related to dulcite. (*P. J.*, 1894, 231.)

Brassica.—In China the oil of *Brassica sinensis*, or *petsai*, is used for lighting, and is said also to be purgative, and useful in *skin diseases*, while the Japanese employ the yellow oil of *B. Campestris*, L., under the name of *aburana*, for culinary and lighting purposes. (*A. J. P.*, June, 1885.)

Brazil Nuts. *Cream Nuts. Butter Nuts* (not to be confused with the nuts similarly named and obtained from *Juglans cinera* L.). *Para Nuts. Chataigne du Brésil*, Fr. *Paranuss*, G.—These are edible nuts imported from Brazil, and sometimes employed in making cream syrups for giving flavor to carbonic acid water. In Brazil an expressed oil is obtained from them, which is said to be used for burning, making ointments, and adulterating copaiba. The nuts are the product of *Bertholletia excelsa* Humb. et Bpl. and *B. nobilis* Miers, a large and beautiful tree of the Fam. *Myrtaceæ*, growing over extensive regions in South America. Cornwinder has found in the kernel of the nut 65.60 per cent. of oil, and 15.31 per cent. of nitrogenous matter. (*P. J.*, Aug., 1873.) Hugo Kühl obtained from the seeds an average fat-content of 62.73 per cent., with 2.59 per cent. of nitrogen, corresponding to 16.20 per cent. of proteins. (*P. Zeit.*, 1909, No. 6, 58.)

Brazil Wood.—A red dye-wood, the product of different species of *Cæsalpinia*, growing in the West Indies and South America. Two varieties are known in commerce—1, the proper Brazil wood, said to be derived from *Cæsalpinia echinata* Lam., and sometimes called *Pernambuco* or *Fernambuco wood*, from the province of Brazil, where it is collected; 2, the *brasiletto*, produced by *C. brasilensis*, L., and *C. Crista*, L., which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The *Nicaragua* or *peach wood* is also analogous to the brasiletto, and is said by Bancroft to be derived from a species of Cæsalpinia. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its coloring matter to water. It was formerly used in medicine, but has been abandoned as inert. In pharmacy it serves to color tinctures, etc., but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink. Its dyeing properties are due to a crystallizable coloring principle, named *brazilin* or *brasilin*, $C_{16}H_{14}O_5$. This, as usually obtained, is of a sulphur-yellow color, which it preserves in the dark, but in the sunlight, to which it is remarkably sensitive, changes to a reddish hue after a few minutes' exposure, and also more slowly in diffused daylight. The principle should, therefore, be kept in perfectly opaque vessels. It is now stated that when absolutely pure it is colorless, and becomes red on exposure to the air. The change is due to the formation of *brasilein*, $C_{16}H_{12}O_5$, which can be prepared from the brasilin by a variety of methods, such as oxidation by nitrous acid, by alcoholic iodine solution, etc. Brasilin is sparingly soluble in water, yielding a sweet and almost colorless solution which is not changed by acids, but is deeply reddened by alkalies. In alcohol and ether it is somewhat more soluble than in water, giving a light yellow solution. Brasilin and hematoxylin (from logwood) are now recognized as related, each being derived from the pyrone nucleus $C_5H_4O_2$, from which the two groups, the xanthone group and the flavone group, are also taken. The coloring principles of most dye-woods are now referred to this source. (Kupe, *Die Chemie der natürlichen Farbstoffe*, Braunschweig, 1900.)

Brea Gum.—This substance, which has been proposed as a substitute for gum arabic, is believed to be derived from *Cæsalpinia præcox*, a Brazilian tree. It occurs in stalactitic pieces or oval reddish-yellow tears, isolated or agglomerated. It forms with water a viscous, pale reddish-yellow mucilage, of acid reaction, which may be partially decolorized by heating with a few drops of hydrochloric acid. It is said to contain 77 per cent. of arabin.

Bremen Blue or **Bremen Green.**—This substance, chemically, is *cupric hydroxide*, although sometimes *cupric carbonate* is sold under the same name. It is made by precipitating a copper salt with an alkali, and drying the precipitate below 40° C. (104° F.). When used as a water-color, it is blue, but when mixed with oil, a soap is formed which is of a green color.

Bromal. *Tribromacetaldehyde.* C_2HBr_3O.—This substance resembles chloral in its chemical properties, like it existing as an oily, colorless liquid, or, when united with water or alcohol, as a crystalline hydrate or alcoholate. It boils at about 172° C. (341.6° F.), and distils without decomposition. It is prepared by adding, little by little, from 3 to 4 parts of bromine to refrigerated alcohol. After fifteen hours of contact the mixture is distilled. The excess of bromine and the other volatile products come over first, and afterwards, at a temperature of from 160° C. (320° F.) to 180° C. (356° F.), the bromal, with an oily substance insoluble in water. Water being added, *bromal hydrate*, $C_2HBr_3O.H_2O$, is formed in rhombic scales fusing at 53.5° C. (128° F.). Much care should be exercised not to dispense bromal in combination with alkaloidal solutions and tinctures, due to the fact that bromal hydrate precipitates alkaloids from solution. Bromoform is formed when an alkali is added to a solution of bromal hydrate, and an alcoholate separates in a layer when an elixir or a tincture is added. According to S. Steinauer (*V. A. P. A.*, May 19, 1870), in frogs and mammals bromal produces at first great restlessness, followed by sleep of moderate intensity, accompanied by an almost complete analgesia. Dyspnea was usually very marked, and death sometimes occurred in convulsions. The cardiac ventricles after death were relaxed or tetanized, according as the dose had been large or small. Steinauer believes that the succession of symptoms is due to the first action being that of the bromal, and the subsequent, that of bromoform and nascent bromides generated in the blood from the bromal hydrate. Steinauer administered the drug to several patients, in *doses* of three grains (0.2 Gm.) at bedtime, with the effect of relieving pain or producing sleep. In *epilepsy* it seemed to avert the paroxysms.

Bromalbacid. *Albumen Bromate.*—This substance, whose therapeutic action is said to be identical with that of the bromides, is a *bromated egg albumen.* It is soluble in water and is administered in seven to ten (0.48–0.65 Gm.) grain *doses.*

Bromamide. *Tribromaniline Hydrobromide.* $C_6H_2Br_3NH_2HBr$.—This substance, which is said to contain 75 per cent. of bromine, and to be very stable, occurs in odorless, tasteless, colorless, needle-shaped crystals, insoluble in water, but soluble in sixteen parts of boiling alcohol, in chloroform, ether, and the fixed oils. It melts at

117.2° C. (243° F.), and volatilizes at 154.4° C. (310° F.) without change. It has been proposed by A. Caillé (*N. Y. M. J.*, 1892) as an antipyretic, antirheumatic, and analgesic. *Dose*, from ten to fifteen grains (0.65–1.0 Gm.).

Bromauric Acid. *N. F. IV. Acidum Bromauricum.*—The N. F. requires it to "contain HAu $Br_4 + 5H_2O$ (607.97) corresponding to not less than 32 per cent. of gold, Au. Preserve it in glass-stoppered, amber-colored bottles. It occurs as dark red-brown, flat, needle-shaped crystals, or as irregular, coarse granular masses; odorless, and having a metallic and acid taste. Permanent in the air when pure; when chloride is present the salt is deliquescent. Bromauric Acid melts at about 27° C. (80.6° F.). It is very soluble in water and in alcohol. Its aqueous solution is strongly acid to litmus, and yields with silver nitrate T.S. a yellowish-white precipitate, insoluble in nitric acid and but slightly soluble in ammonia water. Ignite 0.1 Gm. of Bromauric Acid, heat the resulting residue of gold with 5 mils of nitric acid, add 15 mils of distilled water and filter; no weighable residue remains on evaporating the filtrate and igniting. Dissolve 0.2 Gm. of Bromauric Acid in 10 mils of distilled water, add 16 mils of tenth-normal silver nitrate V.S. and 12 mils of ammonium carbonate T.S., digest the mixture for ten minutes on a water bath, then cool and filter. The filtrate, on super-saturating with nitric acid, does not become more than slightly opalescent (*chloride*). Bromauric Acid is decomposed on exposure to red heat and leaves a residue of metallic gold equivalent to not less than 32 per cent. of the weight taken."

It is used in the preparation of the N. F. solution of gold and arsenic bromide (see Part III). The *dose* is one-tenth grain (0.006 Gm.).

Brometone. *Tribrom Tertiary-Butyl Alcohol. Acetone Bromoform. N. N. R.* 1916. $CBr_3C(OH)(CH_3).CH_3$.—It is produced by the action of acetone on bromoform in a caustic alkali solution. It occurs in fine, white, prismatic crystals possessing a camphoraceous odor and taste. It is soluble in water and in almost all organic solvents. Brometone is said to have the sedative action of the bromides without the disadvantage of producing bromism. *Dose*, five grains (0.32 Gm.).

Bromile.—This is a combination of bromine with an unknown organic base. It occurs in large white scales, which are soluble in 8 parts of water, and, according to Filippi, represents 24 per cent. of bromine. It is used as a substitute for the bromides, especially in *epilepsy*, in *doses* of from thirty to sixty grains (2–4 Gm.).

Bromine. *N. F. IV* (*U. S. P. VIII*). *Bromum. Brominium. Brome*, Fr. Cod. *Bromum*, P. G.; *Brom*, G. *Bromo*, It., Sp.—Bromine was official in *U. S. VIII*, but it was dismissed and is now official in the National Formulary. "It contains not less than 98 per cent. of Br (79.92) and not more than 2 per cent. of Cl. Preserve Bromine in glass-stoppered bottles in a cool place, the bottle being enclosed in a larger vessel with the space between filled with some substance capable of absorbing and combining with any vapors which might escape." *N. F. IV.*

Bromine is an elementary body, possessing many analogies to chlorine and iodine. It was discovered in 1826 by Balard, of Montpellier, in the bittern of sea salt works, in which it exists as a magnesium bromide. Since then it has been found in the waters of the ocean, in certain marine animals and vegetables, in various aquatic plants, as the water cress, in numerous salt springs, and in the mineral kingdom. It has also been detected by Mène in the coal gas liquor of the Paris gas works. In the United States it was first obtained by Silliman, who found it in the bittern of the salt works at Salina, in the State of New York. It was discovered in the salt wells near Freeport, Pa., by David Alter, and is now obtained in largest amount from the brines of Ohio, Pennsylvania, Michigan, and West Virginia. The chief works are located at Parkersburg and Mason City, W. Va.; Pomeroy, Ohio, and Midland County, Mich. The annual production of bromine in the United States for the years 1914 and 1915 was as follows: 1914, 576,991 lbs., valued at $203,094, and in 1915, 855,857 lbs., valued at $856,307. The bromides contained in the mother liquors of the salt wells are oxidized by manganese dioxide in West Virginia and Ohio, while potassium chlorate is the favorite oxidizing agent in Michigan, because of the large proportion of calcium chloride in the liquor. Much is also produced in the latter state by electrolytic processes.

Preparation.—The original salt liquor or brine is pumped out of the ground at 9° B., evaporated to about 15° in large iron pans, then allowed to settle, and is further evaporated in wooden tanks heated by steam pipes to the point of crystallization of the salt. These tanks, five in number, are placed at different elevations, one above the other. Each day the liquor is run off from No. 1, the highest, to No. 2, next day to No. 3, and so on until it reaches No. 5, the crystallized salt being removed from each tank after draining off the liquor. The brine which reaches No. 5 is bittern, and consists chiefly of calcium magnesium, sodium, and some aluminum chlorides, with varying percentages of sodium and calcium bromides.

The bittern marking 30° to 38° B. is evaporated to about 45° B. By this further evaporation an additional percentage of impure salt is removed; the liquor is then run into stone stills, materials for generation of chlorine added, and heat applied by means of steam until the bromine has been all eliminated and vaporized. It is condensed and collected in cooled receivers. (*Proc. A. Ph. A.*, 1877, p. 448.) A bromine still is figured in *N. R.*, April, 1887; see also *N. R.*, 1883, 108; *Am. Drug.*, 1884, 121. The chief source of the bromine abroad is at Stassfurt in Germany, where the magnesium bromide remains as a residue in the working of the potassium salts. The bromine is extracted from the solution of bromide in a continuous process by the joint action of chlorine gas and steam.

Bromine has also been obtained from sea weeds by carbonizing them, lixiviating the carbonaceous residue, and then separating the ingredients, among which are iodine and bromine. For details, see *Chem. News*, July 6, 1866, p. 2. More than two-thirds of the bromine of commerce is used for the manufacture of bromides for medicinal use, and for photography; the remainder is used for aniline colors.

Properties.—The National Formulary IV gives the following description: "Bromine is a heavy, dark, brownish-red, mobile liquid, evolving, even at ordinary temperatures, reddish fumes, highly irritating to the eyes and lungs, and having a peculiar, suffocating odor, resembling that of chlorine. Specific gravity: about 3.016 at 25° C. (77° F.). Boiling point: about 63° C. (145.4° F.). One mil dissolves in about 90 mils of water; it is

freely soluble in alcohol, ether, chloroform, or carbon disulphide. On exposure to air it volatilizes. It destroys the color of solutions of litmus or indigo, and imparts a yellow color to starch T.S. Add 5 mils of Bromine to an excess of sodium hydroxide T.S.; it combines to form a permanently clear liquid, without the separation of oily drops (*organic bromine compounds*). Shake 10 mils of a saturated aqueous solution of Bromine with a slight excess of reduced iron until it becomes nearly colorless, filter the liquid and add 5 drops of ferric chloride T.S. and 5 drops of starch T.S.; it does not assume a blue color (*iodine*)."

Assay.—"Dissolve 10 Gm. of potassium iodide in 25 mils of distilled water, introduce the solution into a 100 mil measuring flask, stopper and determine accurately the weight of the flask and its contents. Add about 1 Gm. of Bromine to the contents of the flask, determine its exact weight and then fill the flask to the mark with distilled water and titrate 25 mils of this solution with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 98 per cent. of Br with not more than 2 per cent. of Cl. Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.007992 Gm. of Br. or 0.003546 Gm. of Cl. Each gramme of Bromine (containing not more than 2 per cent. of chlorine) corresponds to not more than 128.3 mils of tenth-normal sodium thiosulphate V.S." *N. F. IV.*

Bromine congeals at −7° C. (19.4° F.) and at −20° C. (−4° F.) becomes a hard, brittle, crystalline solid, having a dark leaden color, and a luster nearly metallic. It boils at about 63° C. (145.4° F.), forming a reddish vapor resembling that of nitrous acid, and of the sp. gr. 5.54. It evaporates readily, a single drop being sufficient to fill a large flask with its peculiar vapor.

Bromine is sparingly soluble in water to which it communicates an orange color, more soluble in alcohol, and still more so in ether, chloroform, and carbon disulphide. By the aid, however, of potassium bromide, it may be dissolved to any desirable extent in water. Its alcoholic and ethereal solutions lose their color in a few days and become acid from the generation of hydrobromic acid. It bleaches vegetable substances like chlorine, destroys the color of indigo sulphate, and decomposes organic matters. Its combination with starch has a yellow color. It corrodes the skin and gives it a deep yellow stain. Bromine is intermediate in its affinities between chlorine and iodine, since its combinations with metals are decomposed by chlorine, while, in its turn, it decomposes those of iodine. It forms acids which are analogous in properties and composition to the corresponding acids of chlorine and iodine.

Commercial bromine sometimes contains as much as 6 or 8 per cent. of *carbon tetrabromide*, as ascertained by Poselger. He discovered the impurity by submitting some bromine to distillation, during the progress of which the boiling point rose to 120° C. (248° F.). The residuary liquid at this temperature was colorless, and when freed from a little bromine, proved to be carbon bromine, as an oily, aromatic liquid. It is stated by T. L. Phipson that he has found in commercial bromine, accounted pure, a notable amount of cyanogen, and that it may be detected as follows. Take of iron filings and bromine, of each, half an ounce; add to the filings 2 or 2.5 ounces of water; introduce the bromine very gradually, stirring steadily; filter rapidly while warm from the reaction; and put the filtered liquid in a partially closed bottle. In the course of some hours a deposit of iron ferricyanide (Berlin blue) will have formed, and may be collected on a filter. In about two days the whole of the cyanogen will be deposited. In the samples of bromine thus examined he had found from 0.5 to 1 per cent. of cyanogen. (*Chem. News*, 1873, p. 51.) Chlorine and iodine are frequently found in bromine, the former being more common in American and the latter in German bromine.

In testing for bromine in mineral or saline waters, the water is evaporated in order to crystallize most of the salts. The solution, after having been filtered, is placed in a narrow tube, and a few drops of strong chlorine water are added. If this addition produces an orange color, bromine is present. The water examined, in order that the test may succeed, must be free from organic matter, and the chlorine not be added in excess. Bromine may be detected in marine vegetables by carbonizing them in a covered crucible, exhausting the charcoal, previously pulverized, with boiling water, precipitating any alkaline sulphide present in the solution by zinc sulphate, and then adding successively a few drops of nitric acid and a portion of ether, shaking the whole together. If bromine be present it will be set free and dissolve in the ether, to which it will communicate an orange color. (Dupasquier.) According to Reynoso, a more delicate test is furnished by hydrogen dioxide, which liberates bromine from its compounds without reacting on it when free. The mode of procedure is as follows: Put a piece of barium dioxide in a test tube, and add successively, distilled water, pure hydrochloric acid, and ether. The materials are here present for generating hydrogen dioxide; and as soon as bubbles are seen to rise to the surface, the substance suspected to contain bromine is added, and the whole shaken together. If a bromide be present, the hydrochloric acid will give rise to hydrobromic acid; and the hydrogen dioxide, acting on this, will set free the bromine, which will dissolve in the ether, and give it a yellow tint and the odor of Bromine.

Uses.—In concentrated solution Bromine is a powerful caustic and germicide. Its disinfectant properties appear to be somewhat inferior to those of chlorine; according to Koch, a 2 per cent. solution destroys the anthrax spores in twenty-four hours and Miquel gives the antiseptic limit as 1 in 1600. At one time it was employed internally in *scrofulous* and *syphilitic diseases*, but there is no reason to believe that it exercises any different effect upon the system from the salts of hydrobromic acid, and it has been entirely abandoned as an internal remedy. In dilute solution, from 10 to 40 minims to a pint of water, it is occasionally employed as a wash for *ulcers* but has no advantage over other disinfectants. It has been highly lauded by Goldsmith and others for its caustic and germicidal action in *hospital gangrene*. Applied pure it was found to destroy the diseased tissues more rapidly and thoroughly than did even strong nitric acid. Smith (*A. J. P.*, 1863, p. 202) suggested the following as a convenient formula for the application of Bromine in *hospital gangrene:* Dissolve 160 grains of potassium bromide in two fluidounces of water, add one troyounce of bromine, and, stirring diligently, pour in sufficient water to make the solution measure four fluidounces. The solution should be kept in tightly stoppered bottles. In overdoses it is a corrosive poison. About an ounce ingested caused

violent inflammation of the lips, mouth, tongue, and esophagus, with incessant burning pain, followed, in two hours and a half, by prostration, ending in death. (Snell, *N. Y. Journ. of Med.*, Sept., 1850.) In a vaporized state, it is one of the poison gases so frequently used in the trench warfare in France and Belgium in the European War. The best antidote, according to Alfred Smee, is ammonia, given largely diluted and mixed with sweet oil. Thiosulphates are also antidotes and an effective mask to prevent the inhalation of the fumes is provided by covering the mouth and nose with gauze which has been recently saturated with an aqueous solution of sodium thiosulphate.

Bromine Chloride. *Bromi Chloridum.* BrCl. —This chloride is prepared by passing chlorine gas through bromine, and condensing the vapors which form, by a freezing mixture. It is a reddish-yellow, very mobile and volatile liquid, emitting dark yellow fumes, which have a very powerful odor and cause a flow of tears. Its taste is hot and unpleasant. Lebeau doubts the existence of bromine chloride and states that it is a mixture of bromine and chlorine in which the chlorine is simply in solution in bromine. (*Chem. News*, 1906, 241.) Bromine chloride is used by Landolfi, of Naples, internally, in the treatment of *cancer* and as an ingredient in his caustic.

Bromipin. *N. N. R.* 1917.—*Brominized Sesame Oil* is probably a simple addition compound of bromine with the unsaturated oleins of sesame oil. The exact composition of this substance is not known, but it is asserted to be a stable combination of bromine and sesame oil. It is claimed for it that it has the sedative powers of potassium bromide and other alkaline bromides, but does not produce disturbances of the intestinal tract, skin, and general system which occur in bromism. Bromipin is used like the inorganic bromides in the treatment of *epilepsy, insomnia, neurasthenia*, and other conditions of chronic hyper-excitability of the nervous system. It appears to be more slowly absorbed than the ordinary bromides and therefore exercises a more evenly continuous effect. Although Bermann (*Th. M.*, 1910) has found that the larger part of the bromine appeared in the urine as an inorganic bromide, there is reason to believe that a larger proportion of the bromine of bromipin than of the inorganic bromides is taken up by the central nervous system, because of the fatty combination.

Bromipin is marketed in two forms, one of which contains 10 per cent. and the other 33⅓ per cent. of bromine. Of the weaker solution, which is the one generally preferred, 1 teaspoonful corresponds to about eleven grains (0.7 Gm.) of potassium bromide. The ordinary *dose* of the 10 per cent. bromipin is one-half to one fluidrachm (2–4 mils), which may be gradually increased to two or three fluidrachms (7.8–11.7 mils).

Bromochinal. *Bromoquinal Acid. Quinine dibromsalicylate.* $C_{20}H_{24}O_2N_2.2(C_6H_2Br_2.OH.COOH)_2$.—Bromochinal occurs in yellow crystals, sparingly soluble in water, alcohol, or ether. According to Von Noorden, in *doses* of nine to twelve grains (0.6–0.78 Gm.) given twice a day, it acts as a feeble antipyretic and is also soporific. (*Ther. Geg.*, v.)

Bromocoll. *Dibromtannin-gelatin.*—This is a yellow, tasteless, odorless powder, composed of 20 per cent. of bromine, 10 per cent. of water, 30 per cent. of gelatin, and 40 per cent. of tannic acid. According to the experiments of Brat (*Th. M.*, 1901, xv, 4), bromocoll is very resistant to gastric juice, but is readily dissolved with decomposition in the intestinal juices. It is claimed that it acts precisely like the bromides, but produces the disagreeable symptoms of bromism only in a very mild degree. Friedländer (*Th. M.*, 1901) determined by experimentation that it depresses the irritability of the psychomotor centers. Meier (*Med. Klin.*, 1906) has found that the subcutaneous injection of bromocoll is useful, at least in the lower animals in strychnine poisoning and in *tetanus*. The *dose* is thirty to seventy-five grains (2–5 Gm.) a day.

Bromol. *Tribromophenol. Tribromphenol.* $C_6H_2Br_3OH$.—Bromol is obtained as a white flocculent and gradually crystallizing sediment when bromine water is added to an aqueous solution of phenol. Pure tribromophenol occurs as a white, crystalline substance which melts at a temperature of 92° C. (197.6° F.), and is nearly insoluble in water, but readily so in alcohol, ether, chloroform, glycerin, and in fatty and ethereal oils; the odor is disagreeable, like that of bromine, but more penetrating; the taste is sweet and astringent. According to Grimm and Rademacher, tribromophenol is a powerful antiseptic and disinfectant, which, when in concentrated form, acts as a caustic, and is especially valuable in the treatment of *tuberculous ulcers* and *gangrene*. Grimm considered the remedy too caustic to be used upon the mucous membrane of the upper air-passages, but Rademacher has used it in the solution of olive oil (2 to 30) with asserted excellent results in *diphtheria*. It is said to be very slowly acted upon by the intestinal juices, and has been used as an intestinal disinfectant in *doses* of from three to eight grains (0.2–0.5 Gm.) a day. That it is absorbed in some form is shown by the fact of its excretion in the urine in the form of *tribromophenol-sulphonic acid*.

Bromolecithin. *Bromlecithin.*—This is asserted to be an additive product of bromine and lecithin containing from 25 to 30 per cent. of bromine, and is supposed to combine the tonic effect of lecithin with the sedative action of bromine. It is marketed in the form of tablets, each one of which represents three-quarters of a grain (0.05 Gm.) of the compound. From five to ten tablets may be given daily.

Bromolein is an addition product of bromine in which the unsaturated fatty oleins of the almond oil have taken up the bromine necessary for their saturation. This substance, introduced by Coronedi and Marchetti (*Settimana med.*, 1899, liii), is a yellow, clear, oily liquid, containing 20 per cent. of bromine combined with olein of the oil of sweet almonds. It is asserted that it may be used hypodermically or upon the skin, and affords an excellent means of using the bromides in nervous diseases, acting like the older bromides without causing bromism. It is said also not to be decomposed by the enzyme of the pancreas. The *dose* of bromolein is from one-half to one fluidrachm (1.9–3.9 mils).

Bromo-mangan is a ferro-mangan with the addition of 3 per cent. bromo-peptone which contains 11 per cent. bromine. It is a dark brown liquid of agreeable odor and taste, and is asserted to be a reconstructive tonic, especially efficient in the treatment of nervous conditions associated with anemia.

Bromophenol. *Phenol Monobromate. Orthomonobromphenol,* $C_6H_4Br.OH$, is obtained by the combination of bromine and phenol at a temperature of 150°–180° C. (302°–356° F.). It is a dark

yellow, oily, strong smelling fluid, soluble in alcohol and ether, slightly in water. It is used as a 2 per cent. ointment in the treatment of *erysipelas*, also to disinfect the sputum.

Bromophor.—This preparation, which is stated to be the *dibrom-ricinoleate*, is recommended as an external application in *pruritus* and *erysipelas*. According to Linke, however (*Ther. Neuheiten*, March, 1910), its use in *erysipelas* is not to be recommended because of its intense irritation of the skin.

Bromopyrin. *Monobromantipyrin.* $C_{11}H_{11}BrN_2O$.—This occurs in white, crystalline needles, almost insoluble in cold water, scarcely soluble in hot water, easily soluble in alcohol and chloroform. Its melting point is 114° C. (237.2° F.). Its influence upon the system seems not to have been investigated. A mixture of antipyrin, caffeine, and sodium bromide has also been sold as bromopyrin which must not be confused with the original compound.

Bromosin is a preparation similar to Bromalbacid (see p. 1286) containing 10 per cent. bromine.

Bromotan. *Bromotannin-methylene urea* is a light brown, odorless and tasteless powder, insoluble in water. It has been employed by Rockstroth (*Th. M.*, 1906) in the treatment of moist *eczema*. He finds it especially of service to control the itching. It may be mixed with four to five times its weight of talcum or zinc oxide and used as a dusting powder or as a 10 per cent. ointment.

Bromural. *N. N. R.* 1917. *Alpha-monobrom-isovaleryl urea.* $(CH_3)_2CH.CH.Br.CO.NH.CO.NH_2$.—This occurs as white, almost tasteless, needle-like crystals, soluble in hot water, ether, and alcohol, but only sparingly in cold water. Its melting point is 147°–149° C. (296.6°–300.2° F.). Bromural has been widely employed as a general nerve sedative and as a mild somnifacient. Eeckhout (*A. E. P. P.*, lvii, p. 338) administered to a rabbit 0.1 Gm. daily for two weeks with no apparent disturbance of the health. Sollmann and Hatcher (*J. A. M. A.*, 1908, li, p. 487), however, have found that in cats the relation of the sleep-producing to the fatal dose of bromural was practically the same as that of chloral, and that the effects of bromural come on even more quickly than those of chloral hydrate and last for a comparatively short time. According to Eeckhout, the action is similar to that of the bromides. Takeda (*A. I. P. T.*, 1911, xxi, p. 203) has, however, shown that only a small percentage of the molecule is decomposed in the body, and believes that the drug acts as bromural, not as its constituent parts.

While it is often of service in the milder types of *insomnia*, in severer cases bromural is an uncertain hypnotic. Its most important use is as a general nerve sedative, for which purpose it appears to combine the sedative actions of both the bromides and valerian. Like the bromides it has a certain amount of anodyne power in *neuralgic* pains and like valerian is useful to control the various *hysterical* manifestations. It appears, also, according to the experience of Ferrata and Golinelli (*Gaz. Internaz.*, 1908, No. 13), to exercise the motor sedative effect of the bromides in *epilepsy*. It has also been recommended as a sedative in *asthma*, in *whooping cough*, and for *sea-sickness*. The *dose* of bromural, as a sedative, is from five to ten grains (0.32–0.65 Gm.) several times a day, as may be required, as a hypnotic from ten to twenty grains (0.65–1.3 Gm.) should be administered immediately before retiring. It may be prescribed either in the form of a tablet or as a powder enclosed in a capsule.

Brovalol. *N. N. R.* 1917. *Brom-iso-valeric acid borneol ester. Bornyl brom-valerate. Valisan.* $CH_3CH(CH_3).CHBr.CO.O.(C_{10}H_{17})$.—A colorless, oily liquid, having a slightly aromatic odor, prepared by esterification of borneol with brom-isovaleric acid or its derivatives. It contains 25.2 per cent. bromine. Brovalol has been used as a nerve sedative in the same type of cases in which valerian is employed. It appears on the market in "pearls," each of which contains four grains (0.25 Gm.). The *dose* is one to three pearls, repeated as required.

Brunswick Green.—A color pigment, chemically either *copper oxycarbonate* or *oxychloride*.

Bryonia. *N. F. IV. Bryony.*—The N. F. describes it as "the dried root of *Bryonia alba* Linné or of *Bryonia dioica* Jacquin (Fam. *Cucurbitaceæ*), without the presence of more than 5 per cent. of foreign matter. Usually in circular or elliptical slices, obtained by cutting the root more or less transversely, from 1.5 to 10 cm. in breadth and from 3 to 15 mm. in thickness; the edges light gray or yellowish, rough and striate, the cut surface white or faintly yellow, showing a thin cortex and a wood with numerous projecting, collateral fibro-vascular bundles arranged in concentric zones; fracture short and mealy, whitish internally. Odor faint but distinct and characteristic; taste bitter and nauseous. The powdered drug is of a light yellow color and, when examined under the microscope, shows simple, rounded, or two- or more compound, starch grains from 0.004 to 0.024 mm. in diameter, frequently with a central cleft, tracheæ from 0.035 to 0.25 mm. in width, reticulate or with bordered pores, and large yellow cork cells. Add sulphuric acid to the powdered drug; it becomes reddish-brown and then brownish-purple. Bryonia yields not more than 8 per cent. of ash."
